however, would soon swamp the treasury at a statutory price of one dollar per ounce. If gold is going down, there is no need of increasing the destructive momentum by adding the weight of silver. Actually the limit of productivity for the mines of the Transvaal is now in sight; not many years will elapse before the annual output of gold will seriously contract; the gross production today is lessening, and the relative yearly addition to the world's supply is far below the increase in the volume of business transacted. We are not at all inclined to think that depreciation is the result of the existing accumulation of gold reserves; it is more likely to be found in the changed proportions between producers of raw materials and those engaged in manufacturing and other occupations that add nothing to the fundamental commodity-stocks of commerce.

The recent advance in the price of silver, which began in April, was a logical response to a growing use in coinage. The European nations were employing larger quantities, and the Oriental demand was more insistent than it had been in the last few years before the outbreak of hostilities. Upon our entry into the War it became necessary for the United States to coin more silver to be used abroad in connection with our military operations. It was more convenient than to use gold, and it kept our stock of that metal at home. The upward tendency of the silver market was deliberate but steady until the latter part of August, when the quotation stood at 90.75 cents. From that date the market was distinctly speculative, and trading became wild and unreasoning. A price of 108.50 cents was unjustified, and the sharp recoil has recorded the uncertainty of dealers. Regulation of the price would undoubtedly benefit the producers, but this could not be done except through an international agreement without affecting the gold standard and thereby deranging prices to an even greater extent than at present.

## Exemption From Assessment Work

It is a pleasure to be able to print in full herewith the text of the Act exempting locators and owners of mining claims from the obligation to perform the customary annual labor for holding their claims. The exemption is clean-cut and absolute, without qualification of any sort, and includes not only the present year, but also the year 1918. As approved the bill was designated 'Public Resolution No. 12, 65th Congress (S. J. Res. 78)', and it became law by the signature of the President on October 5. As originally introduced simultaneously in both houses of Congress the measure required certain other performances for the benefit of the Army and Navy, or for the National treasury, in lieu of the regular assessment work on the mining claims. The bill was accepted in committee during the last days of the session, and many congressmen even were unaware that it had finally passed both the Senate and the House. The difficulty experienced in trying to obtain a reliable and authentic

statement may be judged from the fact that we received a positive announcement as late as October 15 from the private secretary of a distinguished senator that the bill had failed. The text is quoted in full from an official copy printed by the Government:

"Joint Resolution To suspend the requirements of annual assessment work on mining claims during the years nineteen hundred and seventeen and nineteen hundred and eighteen.

*"Resolved by the Senate and House of Representatives of the United States of America in Congress assembled,* That in order that labor may be most effectively used in raising and producing those things needed in the prosecution of the present war with Germany, that the provision of section twenty-three hundred and twenty-four of the Revised Statutes of the United States which requires on each mining claim located, and until a patent has been issued therefor, not less than \$100 worth of labor to be performed or improvements to be made during each year, be, and the same is hereby, suspended during the years nineteen hundred and seventeen and nineteen hundred and eighteen: *Provided*, That every claimant of any such mining claim in order to obtain the benefits of this resolution shall file or cause to be filed in the office where the location notice or certificate is recorded on or before December thirty-first, of each of the years nineteen hundred and seventeen and nineteen hundred and eighteen, a notice of his desire to hold said mining claim under this resolution: *Provided further*, That this resolution shall not apply to oil placer locations or claims.

"This resolution shall not be deemed to amend or repeal the public resolution entitled "Joint resolution to relieve the owners of mining claims who have been mustered into the military or naval service of the United States as officers or enlisted men from performing assessment work during the term of such service," approved July seventeenth, nineteen hundred and seventeen.

"Approved, October 5, 1917."

It should be said that any claim-owners who already have performed the statutory annual labor for the current year, either purposely or incidentally in connection with development work that would apply directly or through benefit conferred on adjacent claims, would do well to file affidavits to that effect, stating the amount and cost of the work done, as usual, since it advances the position of the claim toward patentability, and there is a bare possibility that such work later might be made to inure to the further benefit of the claimants through legislation covering a period beyond 1918. It is recommended that such affidavits be filed in addition to the notice of desire to hold the claim under the Exemption Act, and that this is to be done whether the State mining regulations make affidavits of annual labor obligatory or merely permissive.

The last paragraph of the new law expressly states that it neither amends nor repeals the previous resolution relieving enlisted men from the necessity of doing annual labor. This reservation is because the exemption granted by the two bills does not cover identical periods of time; for the general public the relief applies to 1917 and 1918 only, while for those who have joined the colors it extends throughout their term of service.

# Russia in War Time

By HORACE V. WINCHELL

The total area of the Russian Empire is 8,600,000 square miles. Its population is estimated at 181,000,000. The total area of Europe is 3,800,000 square miles and the population about 450,000,000. The climate of Russia is continental and the variation between the summer and winter temperatures is great. The mean January temperature at Moscow is 54° lower than that of July. Central Germany has a temperature-range of 34°. The snow lies for many months over a large portion of the vast Muscovite territory. The annual rainfall in northern and central Russia is moderate, being from 20 to 24 in., but quite sufficient for crops, being distributed throughout the year. As one goes south the rainfall decreases rapidly, averaging from 8 to 12 in., and in the extreme south there is very little precipitation in the fall and winter, so that the period of vegetation is too short to permit the growth of trees. Thus we find the forests of northern Russia contrasted with the steppes of southern Russia, and this contrast makes itself felt in every department of economic and national life. The forest district begins at the Arctic circle, where the trees are coniferous, consisting largely of spruce, fir, pine, and birch, and extends southward to the latitude of Moscow and the upper waters of the Volga. The mixed forest region covers central and western Russia as far south as the Black Sea. In the Caucasus I saw the finest forests of white oak, white ash, Persian walnut, and beech, together with beautiful fir and hemlock.

The population of the coniferous belt varies from 1½ to 36 per square mile. In Finland, which is somewhat warmer, the population is 21 per square mile, but agriculture and stock raising are comparatively unimportant. The population of the mixed forest region is from 50 to 150 per square mile, exclusive of Moscow. The population of the Baltic region is from 60 to 80 per square mile, while Poland, which is extremely fertile, has a dense agricultural and industrial population amounting to 288 per square mile. The great agricultural region of Russia is found in the steppes. This is largely known as the 'Black Earth' region. It has a moderate rainfall and produces all kinds of grain, and large crops of sugar beets. The population is from 120 to 230 per square mile.

PEOPLE. Just as varied as the physical features of the country are its inhabitants. The different peoples have through long years of conquest become united to form one nation, but they are still far from being welded into one race. There are wide discrepancies in language, physical type, customs, dress, and religion. The two main races in Russia proper are the Indo-Europeans in

the south-west and the Finns in the north-east, the Finns being an offshoot from the Mongolian race. Russians or Slavs of Aryan or Indo-European descent amount to about 75% of the population of European Russia. They are members of the Greek Catholic church, of which several sects exist, and they are divided into three stocks. The Great Russians, numbering about 52,000,000 in European Russia, live in territory from which they have driven the Finns, with which people they are somewhat mingled, and thus occupy northern and central Russia, including the north-eastern part of the 'Black Earth' region, and also territory in eastern and south-eastern Russia from which they have driven the Tartars. Physically they are blond, blue-eyed, and vigorous, with broad shoulders and bull necks, often somewhat clumsy, and with a strong tendency to corpulency. Their character has been influenced not only by a long history of subjugation to feudal despotism, but also by the gloomy forests, the unresponsive soil and the rigorous climate, and especially by the enforced inactivity of the long winters. In disposition they are melancholy and reserved, clinging obstinately to their traditions, and full of self-sacrificing devotion to Czar, Church, and feudal superior. They are easily disciplined, and so make excellent soldiers, but they have little power of independent thinking or of initiation. The normal Great Russian is thus the mainstay of political and economic inertia and reaction. Even the educated Russian gives apparently little response to the actual demands of living. He is more or less the victim of fancy and temperament, which sometimes lead to a despondent slackness, sometimes to emotional outbursts. Here we have the explanation of the want of organization, the disorder, and the waste of time, which strikes the Western visitor to Russia. This pessimistic outlook finds expression in the word which is forever on Russian lips—"Nitechevo," 'it doesn't matter.'

The White Russians number about 6,000,000, and probably derive their name from the white color of their clothing. They occupy the provinces of Minsk, Mohilev, Vilna, Vitelsk, and Grodno. They are the poorest and least advanced of the three Russian stocks.

The Little Russians, numbering 20,000,000, are settled in the 'Black Earth' district or Little Russia proper, and in the Ukraine, which includes the provinces of Kiev, Poltava, Kharkov, and Tchernigov. They have also spread into Galicia and north-eastern Hungary, and have colonized in other directions. They are slender and dark, with the emotional southern temperament, and speak a dialect different from the other Russians.

The Cossacks are not a distinct stock, but are descended from the refugees and outlaws that occupied frontier districts between the settled and the nomadic tribes. They were afterward organized as a frontier militia and as a light cavalry. The Cossacks are found in the valley of the Don, in the Urals, and in Siberia.

About 8,000,000 Poles are found in western Russia. Other races included within this vast nation are the Letts, 1,400,000; the Lithuanians, 1,200,000; Germans, 2,000,000; Swedes, 370,000; Rumanians, constituting the bulk of the population in Bessarabia, 1,000,000; Bulgarians and Greeks, who are fairly numerous in southern Russia; Jews, 5,100,000, until recently not permitted to live in either Great Russia or East Russia, speaking a German dialect mixed with Hebrew, but also familiar with the Russian language; Mongolians, of whom there are said to be 9,000,000 in Russia proper, and many more in Siberia; 170,000 Kalmucks of Mongol blood professing the religion of Lama; the Ural Mountain people, 5,400,000, consisting of eastern Finns, which includes the Ugrians, the Permiaks, the Syryenians, the Samoyedes, the Volga Finns, the Votyaks, and the western Finns, amounting in all to nearly 4,000,000, including the true Finns, the Esthonians, the Lapps, the Tchudes, and the Livonians. There are also Mohammedan Turks, Tartars of various branches, Bashkirs, Kirghizes, and many others, including Georgians, Lesghians, Daghestanians, and more besides. It will thus be seen that, if in America we have a melting-pot of nations, in Russia there is a racial volcano from which eruptions may be expected for a long time to come.

**ECONOMIC CONDITIONS.** Russia, by virtue of its geographical situation, its natural features, and its history, is a land of raw products, although in the past 50 years the manufacturing industry has developed rapidly. Fully 80% of its population lives by agriculture, yet only 26.2% of the total area is under tillage, and 15.9% is devoted to gardens, meadows, and pastures. Forests cover 28.8%, and 19.1% is wholly barren. The manufacturing industry is as yet of minor importance. There is a great lack of native capital and of competent workmen. The products are limited to articles of common use for distribution in Russia and in central Asia. In Poland the predominant industry is the manufacture of cotton and other textiles. One important industrial district in central Russia extends on the south from Moscow to the coalfields of Kaluga and Tula, on the north to Tver and Yaroslavl, and on the east to Ivanovo and Vladismir. The chief manufactures here are textile and metal wares, together with wooden articles. The iron industry of southern Russia, where coal and iron are found together in the Donetz basin, has already materially decreased the imports from foreign countries, and a few years before the War it developed a small export trade. This district now has a production twice as great as the old and famous iron district of the Urals, where charcoal and lignite were used for fuel.

There are manufacturing establishments producing

cotton, metal wares, machinery, and chemicals in the cities on the Baltic, such as Petrograd and Riga. In Finland the great abundance of timber and water-power support wood-pulp, paper, and other industries, and in the steppe-region are flour mills and beet-sugar factories.

The railroad system of European Russia is nearly as large as that of Germany. Considering mileage alone, 25,447 miles were open for traffic on January 1, 1912, but the ratio of mileage to area was one mile of railroad for every 59 square miles of territory, which is less than for any other country except Norway. The United Kingdom has one mile of railroad for each 5.3 square miles; Germany one mile for 5.8, and the United States one mile for every 15.7 square miles. The Russians use a broader gauge than the other railroads in Europe and this difference is a serious obstacle to through traffic.

The people of Russia, including the Jews and nomads, are divided into four classes: nobles, officials, clergy, and peasants, the latter including the laborers. The really sharp distinction, however, is that between the great mass of the people on one side and the hereditary and official nobility and the burgess class on the other. Alongside of the admirable achievements in all spheres of intellectual activity, we find also a great deal of merely outward imitation of Occidental forms with a tendency to rest content with a veneer of Western culture and a stock of Western catch-words. Side by side with the unquenchable desire for scientific knowledge, which shuns no sacrifice, and is constantly drawing new elements from the lower classes, there is only too often a total inability to put into practice and to make efficient use of what has been learned. Fancy and emotion are much more widely developed in the soul of the Russian than true energy and joy in creation. The upper classes are noted for their luxury and extravagance, and for their reckless gambling, their better side showing itself in their unlimited hospitality. The lower classes live in unspeakable poverty and destitution. Beggars are numerous and troublesome, especially in the vicinity of churches. At the present time conditions of living are most difficult. With the declining value of the Russian ruble, which is normally worth 51c., and which is now quoted at about 14c., with its actual purchasing-power still less, together with the extremely high prices asked for whatever small stocks of supplies still remain in the hands of the merchants, it is a wonder how the ordinary individual can support himself and his family. A pair of boots costs from 100 to 200 rubles, and can be obtained with difficulty even at such prices. Food of all kinds is scarce in the larger centres of population, and can be obtained only in limited quantity by means of bread-cards, sugar-cards, and the like. A lemon or a small apple costs from one to two rubles. A Russian pound of strawberries, which is nine-tenths of a pound avoirdupois, costs from two to four rubles. These strawberries, by the way, are the finest I have ever eaten. I saw canteloupe selling at 40 rubles; cucumbers, of which the Russians are very fond, at one to two rubles each. No white bread was to

be had in even the best hotels in Petrograd and Moscow for a number of weeks before my departure. The Russian black bread seemed to be composed of tar and cobblestones. I broke two teeth upon this locally esteemed Russian delicacy.

The procuring of a railroad ticket is a matter of extreme difficulty, and it was not an unusual experience to wait two or three weeks, sending a man each day to stand in line at a total expense of perhaps 100 rubles, to find your space in the train occupied by soldiers who had

ever assembled in one country. From 15,000,000 to 18,000,000 men have been taken out of industrial life, and, regardless of their usefulness to the nation in the fields or factories, are now being supported in idleness. The quantity of man-power now rusting and doing nothing but eating and talking is appalling. During the last three months of my sojourn in Russia I saw hundreds of thousands of soldiers, but not once during that time did I see a soldier drilling, although I passed hundreds of barracks and drilling grounds, nor was my heart glad-

PETROGRAD AND BRIDGE ACROSS THE NEVA

taken possession and were going home for a vacation, or returning to the front, or deserters who had paid no fare whatever. It was even the experience of myself and wife to be obliged to stand up in the corridor outside of a first-class compartment all night long, while nine soldiers occupied, free of charge, the space for which we had waited weeks and had paid full rates.

The entire Russian people, men and women, are mobilized for war and are under military orders: Every person over the age of 18 must have a passport, and the men all wear uniforms and are drafted for military duty. Thus Russia has under arms the greatest number of men

dened once by the sight of a squad of these men working upon the roads or engaged in useful occupation. It is true that many of the idle soldiers find ways of earning money. They act as porters at railway stations, asking ten times the normal fee, and perhaps absconding with the baggage entrusted to their care. They are the only purveyors of food and clothing when there is absolutely none to be had from the merchants. More than once we were able to buy from some soldier butter, bread, sugar, and other commodities when none could be had at the stores. I was informed of an instance in which a railway bridge was washed away, the rails and ties remaining,

and a board-walk laid to permit the foot-passengers to cross. One lady engaged two soldiers to carry her baggage across. They agreed upon a price of 10 rubles. Upon reaching the middle of the stream the soldiers informed the lady that if she did not immediately pay them 100 rubles they would throw the baggage in the river. She finally compromised by paying them 65 rubles, all the money on her person, and got her baggage across. I had a similar experience with some horse-packers in the Caucasus. I engaged them for a week at a certain price. When we were a few days out they demanded more, threatening otherwise to leave me in the mountains without horses. I promised to accede to this, but when we reached the end of our journey I paid them the price originally agreed upon and no more.

It is not, however, the common people alone who are thus biased as to their understanding of the sacredness of a contract. The Government owns the telegraph service and many of the railways. The managers of these public utilities are Government officials; yet it was the universal practice for the telegraph companies to exact three times the regular rate for a telegram, saying that there was great congestion and that a telegram must be rated as 'urgent' in order to receive attention. After accepting triple payment these Government officials would perhaps put a postage stamp upon the telegram, or would pay no further attention to it whatever. Occasionally telegrams from Petrograd to the Caucasus would come through in 10 days. Occasionally they arrived after three weeks and frequently not at all. Likewise with the railway officials. I paid several hundred rubles to have my baggage transported by railway from Petrograd to the Caucasus. On arriving at the Don river, where a bridge was out, I found thousands of soldiers fighting for a chance to cross upon the small steamers, and there was no possibility of getting my baggage across unless I took it myself. I was told that the bridge might not be repaired for a month, but that the baggage would eventually be forwarded. Having heard so many tales of the loss of baggage I took my trunks from the possession of the railway company on the west side of the river Don, and at an expense of 300 rubles and after much labor, I got it across the river and presented it to the officials of the same railway on the eastern side of the river. These officials informed me that having once taken my baggage from the custody of the railway, it was again necessary to pay several hundred rubles to get it carried to its destination.

I could relate many instances of Governmental graft that came within my own experience or that of my friends. Every merchant who has succeeded during the last three years in getting merchandise ordered for the Government or for private consumption from Archangel or Vladivostok to Petrograd will tell of innumerable instances in which he has been obliged to pay extortionate graft to the railway officials before he could get a car in which to forward his freight. At the time of leaving Russia factories were closing, and all kinds of business was rapidly coming to a standstill. The workingman has

no conception of a limit to what he may demand. Pay has been increased and hours shortened again and again. Efficiency, which was never great, has fallen off to such an extent that no one can operate at a profit, notwithstanding the high prices commanded by his products. Take for example the cost of mining coal in the Donetz basin; before the War this may have been at most three rubles, or \$1.50 per ton. At the present time the cost is not less than \$8 gold, and is probably nearer \$12. Manufacturers in this district are losing money. They are required by the Government to continue operating, and as a result they are borrowing from the Government to meet their payrolls.

Politically the situation in Russia is decidedly mixed. There are many different parties and no one can say which will secure the adherence of the mass of the people. These parties include the following:

First: Anarchists.

Second: Quite similar to the anarchists, but denying this appellation, since the object of the anarchists was to establish a Government without laws and primarily to overthrow the Czar's régime, which has been accomplished, are the Maximalists or Bolsheviki. These Bolsheviki are extreme socialists who demand confiscation of all kinds of property without compensation and the carrying on of all business by the Government.

Third: Minimalists or Mensheviki. These are socialists whose programme includes the taking over of all forms of business by the Government, and involves Government ownership of all lands now in private estates, but they do not demand that this be done without compensation to the present owner.

Fourth: The Social Revolutionists, whose programme is still somewhat more moderate.

Fifth: The Labor Group allied with the previous two, but concerned more with labor questions than with the question of land ownership.

Sixth: The National Freedom party, the 'Narodniki', or Liberal party, of which Miliukoff, Lvoff, and others are members.

Seventh: The Octobrists, or Monarchists, who believe that Russia is not yet ready for a democracy and who wish an autocracy to be re-established.

Eighth: The extreme right or supporters of the old Czar, Grand Dukes, and the rest.

Today the Socialists are in power, but not the most radical section. The Bolsheviki are the most dangerous and make the most noise. They are the disturbing element; they consent one week to the authority of the Provisional Government and the next week, because this government does not act in all respects in accordance with their demands, they revolt against it. The Liberal party has been forced into the background. Its members are some of the finest men in Russia, but they are persons of markedly Russian type, lacking in both determination and executive ability. These men had for years spasmodically striven to educate the people and to bring about political reform. When the revolution was accomplished they were appointed Ministers under a Pro-

visional Government, and had it not been for the strong socialistic tendencies and propaganda of the soldiers and workmen, there would have been established in Russia under their guidance one of the most advanced democracies of the world. Miliukoff is a splendid character. He was lecturer on international law at the University of Chicago. He has traveled. He is a magnetic speaker, and is one of the finest men in Russia today. Fearless and honest, he, it was, who at the risk of his life, denounced in the Russian Duma the former Prime Minister Stuermer who was accused of being a German spy and a traitor to Russia, and who is said to have died in Petrograd on the eve of his trial for treason. The former Minister of War, Sukhomlinoff, has been condemned to life imprisonment for betraying his country; and Protopopoff, former Minister of Railways, is still awaiting trial. These men were accused of being in the pay of Germany, and are said to have been directly responsible for the loss of hundreds of thousands of Russian lives.

Now, as to the future: Americans are interested to know what can be expected of Russia, first in the present War; second, as a land of opportunity after the trouble. It is my belief, although I realize that no one can speak with any assurance, that there is at present no general sentiment in Russia for a separate peace with Germany. The majority of the people do not favor it. I believe further that, although disorganized, Russia will continue to hold a line which will require the presence of large German and Austrian forces in opposition. I do not look for any great and general offensive by Russia, certainly not this year. No country in the throes of a revolution can at the same time vigorously conduct a foreign war. The wonder is that she has done so well. I do not believe Germany will get to Petrograd, nor will she capture large stores of food in Little Russia; but even the taking of Petrograd would not mean Russia's downfall or surrender. Russia is too great. There is too much territory and, as someone has said, "Russia is like a feather-bed—the further you push in the more you smother." Moreover, the Russians themselves have not that sentimental and affectionate feeling for Petrograd that they have for Moscow. Russia is no place today in which to set on foot new industrial enterprises. Labor is too scarce, too inefficient, and too expensive. Titles are insecure until we know whether or not the socialistic programme is to be carried out to its full extent. Taking a broad view, I should say that Russia is a land of opportunity. The favorable and unfavorable factors may be summarized as follows:

Among the favorable factors I would specify, (1) governmental and political, (a) the country is now on a democratic basis. It is the general belief that it will remain so and will become an advanced republic; the Octobrists and Czarists are in the minority, and only the unexpected failure of the efforts now being made to preserve the freedom of the people will make it possible for the monarchists to organize a successful counter revolution; (b) there are able men in Russia, men of character and of patriotism, and some of these are conducting

its affairs. Kerensky is one of the strong figures in public life today, and in determination and fixed endeavor he is a super-Russian. So long as he remains the guiding spirit the Russian people will be in excellent hands for the solving of their problems and the working out of their destiny; (c) the United States is looked upon as a sincere ally. The Russian people are proud to feel that they are politically on a par with us, and they wish to show us that they are worthy of our trust; (d) the War is sure to result favorably for us and for them. Whatever aid we, as a nation, may render to Russia will be appreciated, and our investments will be repaid tenfold in the satisfaction derived from the performance of a duty to a struggling people and in the industrial opportunities which will surely develop; (e) the old laws which were frequently impracticable and discouraging to foreign investors are now being revised and simplified. (2) Practical consideration of the favorable side of the case needs to take into account, (a) that the great territory of Russia and Siberia is the largest undeveloped domain. Other things being equal and favorable, it presents the largest field for exploration and the investment of capital; (b) it is in the north temperate zone, and covers a wide range of climate and latitude. Its products are as varied as those of the United States, both in mineral and agricultural wealth. Its population, which is already nearly twice as great as ours, is rapidly increasing; (c) whatever the form of its future government, the country is now on the eve of great development, and will furnish a market for all forms of products, especially those which can be manufactured and produced within its borders; (d) the people are friendly by nature, and especially friendly to Americans. They are also moderate, and will, I think, with a little education, be fair in their dealings with us; (e) prohibition prevails throughout the land, and there is no disposition to make a change in that respect; (f) although there is need of money for large undertakings, there seems, nevertheless, to be an abundance for the purchase of every-day necessities and luxuries; (g) Russia no longer trades with Austria nor with Germany, which latter country formerly supplied the greater part of the Russian imports; (h) she no longer wishes to trade in a large way with England.

The unfavorable factors are the following:

(1) Governmental and political; (a) The present Government, which is frankly provisional, will exist only so long as it holds the confidence of the soldiers and the people. The organized force behind it has limited power for compelling obedience to its mandates. Under the guidance of patriotic men who seek only the common good, it finds itself obliged to decide between the selfish and conflicting demands of the various classes of society, many of whom, especially the peasants and laboring men, have not the slightest conception of the meaning of the words 'freedom' and 'democracy'. The ship of state is in perilous waters, and requires a skilful skipper. Among the temporary ministers are representatives of all classes with the possible exception of the peasants, and an occa-

sional clash of interests is unavoidable. The socialists demand the distribution of lands formerly held by the Cabinet and now in large estates (two different varieties of large holdings); the laboring men clamor for concessions and privileges which they believe are enjoyed by laborers in other countries; the tribes are demanding freedom and even rising in revolt to obtain it, although lacking entirely in the ability to govern themselves; and the soldiers have an idea that 'freedom' means that they can have everything without price, and, often in large numbers, are riding on street-cars and railroad-trains without paying fare; and while there is rejoicing over what has been accomplished, there is also unrest and apprehension for the future. (b) The concessions which have already been made to the Poles and Finns, without requiring any guarantee of future support and allegiance, are felt by some to constitute a menace. The same may be said of the privileges thus early granted to the workingmen. (c) The old Russian laws, most of which remain in force, are cumbersome and inapplicable to business. Until they are revised, new enterprises will of necessity be undertaken with great caution. (d) The Jews, who are returning to Russia in great numbers, and who have long exerted an influence beneath the surface, are now becoming more outspoken and often arrogant. Their presence will be valuable in a way, for they are already acquiring property which formerly they were forbidden to hold, and will not favor the confiscation of real estate, but if they become too bold and prominent disturbances will arise from existing racial antipathies.

(2) PRACTICAL DIFFICULTIES. (a) The most obvious difficulty in the way of business at present is the lack of transportation. The railway systems are totally inadequate. Rolling stock is out of order, and little effort seems to be made to repair it. Repair shops are needed, but even if provided there would be no mechanics to fill them. There is a shortage of every conceivable commodity all over the Russian dominions. It is impossible to get freight forward. Most of the available cars and engines are needed for transporting troops and war-supplies. Hundreds of thousands of tons of freight have been lying for months at Vladivostok without means of moving it to the western centres of population. Nothing but war-supplies may be brought over the railways from Archangel and Mourman. There are but few wagon-roads, and those very bad. The railroad from Sweden is almost useless for handling freight since the neutrality laws forbid the bringing of supplies that way. What is most needed just now is 10,000 American railroad men and mechanics to build shops and repair the rolling-stock already on hand and to operate the Siberian road properly, and thousands more of new cars and hundreds of locomotives from the United States; but to such a programme there is an objection which will be mentioned later. Transportation now is frightfully slow, and this applies as well to passenger traffic. The American railroad commission is doing much to improve the situation, but it is still bad. (b) In the next place there is a lack

of men for almost every kind of work, and when they can be hired they are arbitrary, expensive, indifferent, and unreliable. (c) There is an inordinate number of holidays, about 30 under the old régime, each lasting from a day to a week, and during these festal occasions laborers of all kinds refuse to work, stores are closed, the post-office goes out of business, hotels and restaurants refuse to serve meals, and industry is out of joint. (d) The Russian workman cannot be said to be particularly industrious or efficient. He has little initiative and less executive ability. For ages he has been dependent upon his master, has earned little more than his keep, and has not learned to think for himself. His ideas now are greatly confused, and he spends a considerable portion of his time discussing with his mates the wonderful thing that has happened and what to do. The results of his deliberations are sometimes grotesque indeed. Whatever the outcome, the present effect is low efficiency and poor discipline. (e) In these days when the people see property of various kinds being confiscated by the new Government, they are apt to believe that there is no limit to possible confiscations. There is a desire on the part of the proletariat to take from those that have and give to those that have not; and there is fear on the part of those who have that they will not long be permitted to own and enjoy that which they possess.

In spite of the inability of the Russians to furnish all the supplies needed for the army and at the same time provide ample supplies of food, fuel, clothes, and other necessities for the non-belligerents, there is an insuperable reluctance to permit Americans or anyone else to perform this service for them. In their pride and in their desire to develop their own resources they object to the introduction of foreign labor or manufactured products. Thus they are in dire need of railways, but in their charters for new roads they always require the use of rails and other structural materials of Russian manufacture, even though it is quite apparent that these cannot possibly be obtained. They need skilled men in their shops and factories and for operating their railroads, but will not permit them to be imported even for the time necessary to put things in order. Under these circumstances it will be next to impossible to render them the greatest service within our power.

In summing up the Russian situation I will quote a well-known Moscow merchant now in this country: "Day after tomorrow Russia will be all right, but there may be a long day and a couple of dark nights in the interval."

To the business man I would say: "Keep your eyes on Russia, but your money out of it for the next few years." To the younger men, students of business and of engineering: "Study the language of Russia, become familiar with its history, its geography, its people. The time is near when such knowledge will be valuable and will command high wages and will offer rich rewards in the opportunity to take an active part in the development of a great nation."

# Skip-Changing Devices at the Butte Mines

By THEODORE PILGER

The continued development of greater orebodies in the Butte district and the increasing average depth from which the ore is hoisted have made necessary the adoption of more advanced methods of handling both

neath a single-deck cage on which the station tenders ride. The fact that all workmen at Butte are lowered on 'company time,' that the shafts are already pushed to the limit of capacity for hoisting ore, and that all the

Fig. 3

men and ore, to secure greater capacity and to save time. At first a single-deck cage was used, for all purposes. Then a cage was added below, then another, and another. As the mines continued to enlarge, some more

shaft repairing that can be accomplished has to be done between shifts, makes important every minute that can be saved in the handling of men. This condition led to the development of changing devices which would admit

Fig. 4-A.

Fig. 4-B.

rapid method of hoisting than could be done by hoisting mine-cars and tramping them to the ore-bins had to be devised. The mechanism used for this purpose in the vertical shafts at Butte is the skip with trunnion-wheels and half shoe, hung by a cross-head and bail from be-

of a rapid change from skips to multi-deck man-cages, and the reverse. There are several systems of these skip-changing devices now in use in the Butte mines, namely, the underground-chamber method, such as is employed at the Anaconda and St. Lawrence mines;

the head-frame chamber system, as seen at the Leonard; and the overhead-crawl system in use at the West Stewart and the new shaft of the Black Rock.

In the old incline-shafts the changing device was as follows: The skip to be taken off was pulled up high in the head-frame, a section of the guides below the skip was then swung to one side, and the skip, which ran on wheels, on being lowered, would be run upon a horizontal carriage that had in the meantime been pushed on tracks over the collar of the shaft. The cables were then detached, and the carriage carrying the skips was run back upon the tracks from the hanging-wall side of the shaft. Other carriages for transporting man-cages would be run over the collar of the shaft, the cables attached, and the cage hoisted into the head-frame. The guides then swung back into place, were locked with pins, the empty carriage was withdrawn from above the shaft, and the operation was complete.

This plan could not be used in vertical shafts because the angle at which the cages must be removed was too great. The advantage of the method was that the skips and cages resting on these carriages could easily be run directly to the shops for repairs, which can more easily be made when the cages are in a horizontal position than when suspended or lying at an angle. As the inclined shafts were gradually discarded on account of their general inconvenience, great cost of maintenance, and the great proportion of power wasted in hoisting, the underground-chamber method was developed in connection with the vertical shafts, and still is in general use in the older mines of the district. The essential parts of this system are an underground-chamber containing two sets of inclined guides in each compartment, radiating from a point above the collar of the shaft (Fig. 1) at which point the swinging guides in the hoisting compartment are pivoted. This chamber is just below the collar and is usually on the side of the shaft through which hoisting is done. It is timbered all round, and is deep enough below the bottom end of the swinging guides to accommodate the longest set of cages that would be employed at the mine.

The swinging guides, about five feet longer than the longest cages, are locked in place at the bottom when they are in regular hoisting position. They are built of two angle-irons placed back to back several inches apart, riveted on a plate with maple guides for fillers (Fig. 2). The bottom end is pulled out to match the inclined guides which extend downward into the chamber and carry the skips and the cages. The swinging guides are pulled over the chamber by means of a compressed-air cylinder and are stopped at the proper place to match the inclined guides by lugs provided for that purpose. As these guides are usually pivoted just below the skip-dump in the head-frame, and from 20 to 30 ft. above the collar of the shaft, it is necessary to have doors in the platform at the collar, so placed that they can be opened to allow the guides to swing at the bottom. This door is also opened and closed by means of a compressed-air cylinder.

The procedure in making a change from skips to man-cages in the underground-chamber system is as follows: The station tenders, on coming to surface, spot the skips so that they are hung between the swinging guides. They then raise the door at the collar of the shaft, go below, and, having unlocked the swinging guides, pull them over at the bottom until they match the inclined guides which extend downward into the empty chamber. They then signal the engineer to lower until the skips are in their resting positions. Having withdrawn the king-bolt, the cables are pulled over and attached to the man-cages and the swinging guides are placed to match the inclined guides on which the man-cages are resting. They now signal the engineer to hoist until the man-cages are in proper position on the swinging guides, then push the swinging guides by means of the air-cylinder into position in the hoisting compartment, lock them, and the cages are ready for use. When the new head-frame of the Leonard mine was erected, the device was changed in so far that the chamber was built into the head-frame above ground and below the ore-bins. This was possible here because the skip-dump was more than 75 ft. above the collar of the shaft and because the ore-bins are set back about 20 ft. from the shaft. This arrangement is exactly the same as the underground-chamber method in every other particular.

The latest method which has been installed at the No. 3 shaft of the Black Rock mine, and which is an improvement on the method in use at the West Stewart mine, where the idea originated, consists of swinging the skip from the hoisting compartment upon an electric-power crawl which runs on the bottom flanges of an I-beam, placed parallel to the long direction of the shaft and about six feet from it (Fig. 3). This beam is suspended under structural steel frame-work as shown in the accompanying illustration. It is high enough above the platform level to give clearance for four decks of cages, and is below the skip-dump. It branches at one end, having a switch that can be operated from the platform delivering to two similar I-beams from which the spare cages and skips are suspended. A separate crawl is provided for each skip and for each cage, and these crawls are run into place as required. The crawls, as shown in the illustration, are provided with two pieces of steel-cable about seven feet long, on the ends of which are fastened the hooks used to support the cages and skips when taken off the hoisting cable. The skips and cages each have two eyes (Fig. 4A and 4B) fastened to the cross-head and extending through the bonnet into which the crawl-hooks are fastened. The guides are hinged for a distance of about five feet longer than the length of the four-deck cages. These guides are built up of two angle-irons with the corresponding flanges turned together and the space between filled with the usual maple guides. They are all hinged on a rod extending the full length of the guide and are locked every 12 ft. simultaneously (Fig. 5).

The method of changing skips with this device is the following. The station tenders, on coming to surface,

signal the engineer to lower the skip below the hinged guides. These are then opened and the skips raised until the eyes on the cross-head of the skip can be

skip out of the shaft compartment. The king-bolt is withdrawn from the skip, which is then run on the crawl to its receiving side track. The cage is now run

Fig. 2.

Fig. 5.

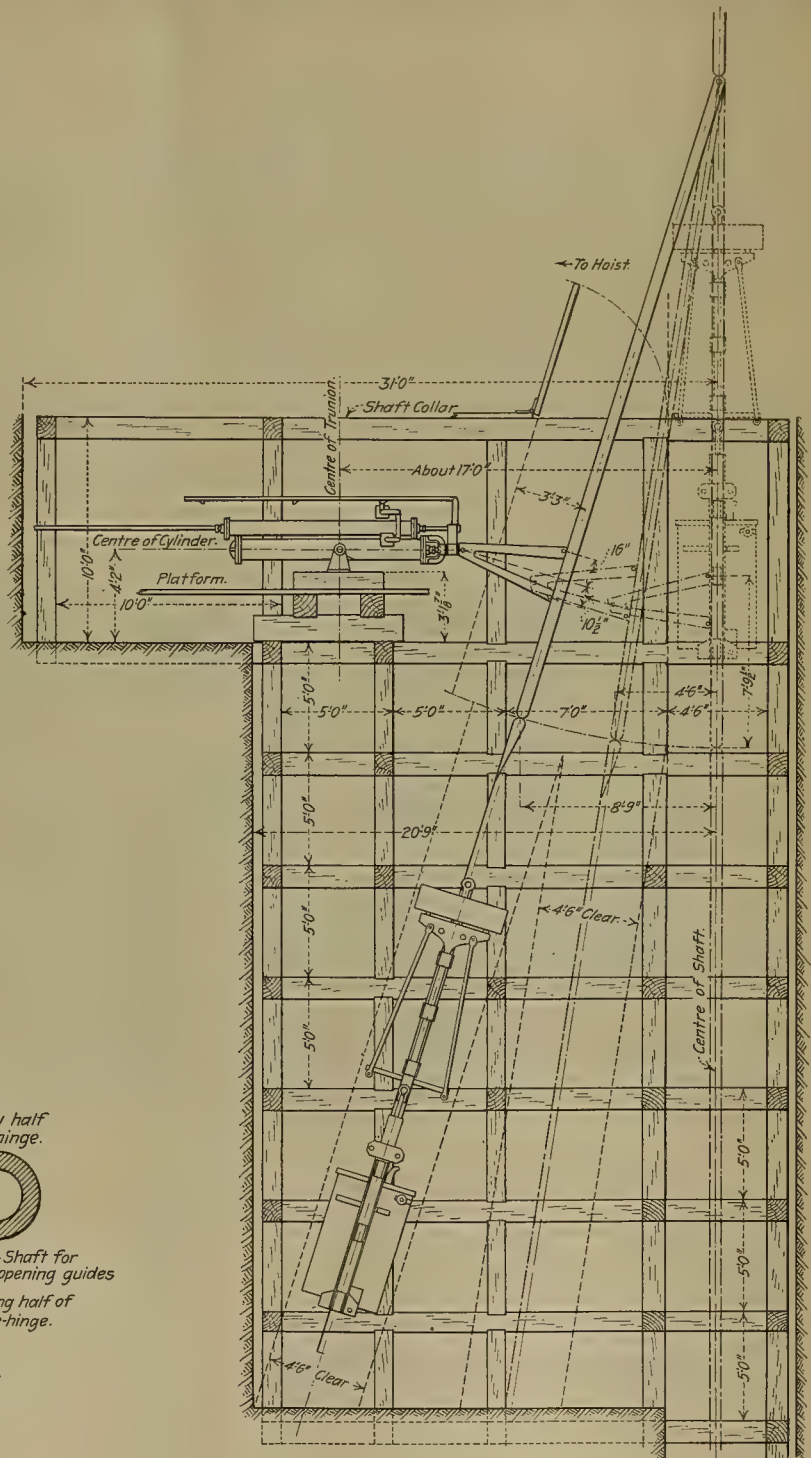

Fig. 1.

reached with the hooks attached to the crawl. They are lowered until the weight of the skip, now hanging from the crawl instead of from the hoisting cable, pulls the

from its receiving side track over a switch to the main beam, the hoisting cable is attached, and the engineer is signalled to hoist until the weight is taken off the crawl,

when the cage swings of its own weight into proper position in the shaft. It is then lowered to the guides, the hinged guides are closed into position and locked, and the change is complete.

The advantages of the underground-chamber system over a surface-change system are that it can be used readily on low head-frames, that it requires no surface-space, and the station tenders, who are perhaps wet through from riding the shaft, do not need to make the change in the wind and cold. Its disadvantages lie in the fact that it is almost impossible to make any satisfactory examination of the condition of the skips and cages, and that it is hard to discover defects, or to make repairs in a dark dirty hole underground. Furthermore, this chamber, being at the collar of the shaft, is generally in loose shifting ground, perhaps in an old dump, and the cost of holding the chamber open and keeping the shaft in good shape is very high. Also, in both the underground-chamber system and the head-frame chamber system, the skips and cages stand at such an angle that repairing is difficult. Another source of great trouble has been the compressed-air cylinder used in pulling back the swinging guides to match the inclined guides in the chamber. The connection to the bail which pulls these guides has a swivel-joint and the cylinder itself is on a rocking base, but nevertheless the piston is continually buckling and binding. The air-cylinders often freeze and cause a great deal of delay as well as danger from fire in being thawed. The door in the platform binds, particularly in winter, and often has to be opened with bars. Finally, the heavy skips and cages in passing over the swinging guide, which is fastened only at top and bottom, hammer the ends of the guide and cause it to buckle.

In the new surface-change system the greatest advantage lies in the facility with which examinations and repairs can be made on the cages and skips above ground and while they are held in a vertical position. If it is necessary to take any to the shops they can be lowered from the crawl directly upon the trucks. If it be desired for any reason to support them from the bottom they can be blocked up. The switching device will allow for the storage of extra skips and cages without the delay of hoisting which was incident to the underground-chamber method. The principal advantage lies in the fact that the taking off and changing of cages does not occupy any of the regular hoisting time because the new cages can be raised to the crawl and stored for emergency without the use of the hoisting engine.

The underground-chamber method will cost 50% more to install than the surface-rig, and furthermore, the expense attached to the up-keep of the surface-change system will be very little, while the underground-chamber requires constant repairs.

POTASSIUM NITRATE is reported to have been found recently as a constituent in dark gray arenaceous shale in Presidio county, Texas.

## Photo-Micrographs in Color

Lantern slides representing photo-micrographs of sections should closely resemble the appearance of the section itself. This can be attained by making the print in stained gelatine instead of by the usual photographic process. The procedure for making such a print is as follows: Lantern plates (Seed or Standard plates are satisfactory) are sensitized by bathing for five minutes in a 2½% solution of ammonium bichromate containing 5 cc. of strong ammonia to the litre, the temperature of the bath being not above 65°F. The plates are then rinsed for two or three seconds in clean water, drained, and dried as uniformly as possible, the plates being kept in the dark during drying. The sensitized plates are then exposed through the glass under the negative to the light of an arc-lamp, the average exposure being about three minutes at 18 in. distance. Printing cannot be done by daylight, or sharp images will not be obtained. The exposed plates are then developed by rocking in trays of water at about 120°F. until all soluble gelatine is removed. Under-exposure is indicated by the high-light detail washing away, and over-exposure by the film being insoluble to too great a depth. The plates are then rinsed in cold water, fixed in hypo, and washed free of the hypo. They are then ready for staining. The staining is done with a 1% solution of dye containing 1% of acetic acid, the dye being selected to stimulate most closely the original stain of the section, the time of dyeing being chosen so that the necessary depth is obtained. When sections stained with two different colors are being photographed negatives are made through suitable color-filters and are then dyed in the two stains and placed face to face so that a two-color slide is obtained. For example, suppose that a section is stained red and green. Two negatives are made on pan-chromatic plates, one with a red filter, which will cause the green to appear as clear spaces in the negative and will not record the red, and the other with a green filter, which will record the red and not the green. The slides made as described from these in bichromated gelatine are stained—that from the red negative with the original green stain, and that from the green negative with the original red stain.

The filters required can be chosen from the set prepared for photo-micrography under the name of Wratten M filters. The choice of the filter is decided by visual trial under the microscope, the filters chosen being those which most nearly absorb one color and transmit the other. Thus, photographing a section stained with Delafield's hæmatoxylin and precipitated eosin, the *A* filter (red) shows no trace of the eosin and gives a good strong negative of the hæmatoxylin. The *B* and *C* filters are used together for the other negative, giving a blue-green color and recording the eosin and hæmatoxylin both fully, and from these two negatives positives are made and stained with a blue and a red dye. Prints thus made beautifully reproduce the original colors.

# Recovery of Converter-Fume at Tooele, Utah

By L. S. AUSTIN

The installation and operation of a Cottrell plant at Garfield, Utah, was described by W. H. Howard in 1911.\* This consists of seven units containing in all 2520 five-inch pipes, 10 ft. long, and was to precipitate the dust and fume from an average of four Pierce-Smith

installations was built to recover converter-fume. O. M. Kuchs describes† a bag-house intended for collecting the lead and zinc fume formed in the converting of leady copper-matte coming from the silver-lead blast-furnace of these works. This was made possible by carefully

COTTRELL TREATER AT INTERNATIONAL SMELTER, TOOELE, UTAH

barrel-type converters, each yielding 25,000 cu. ft. per min. of converter-gas, calculated at standard temperature and pressure. Tests made at a smaller experimental plant upon gases from the blast-furnace, roasters, and reverberatory furnaces, indicated a recovery of not less than 95% of the dust and fume. Mr. Howard states, however, that the results obtained were upon gases particularly favorable to the process, and that it does not follow that all smelter-smoke can be treated so successfully. At the International smelter at Tooele, Utah, a small Cottrell treater for two or three years has been in successful operation for collecting the dust from the Dwight-Lloyd sintering machines, and last year a similar

watching the temperature of the escaping gases, which carried enough volatilized lead and zinc to neutralize the sulphurous anhydride ( $\text{SO}_3$ ) fume produced by converters; but, for those converters when used on straight copper-matte this was not practicable, and to take care of some dust and the abundant fume from this source the more enduring Cottrell apparatus was installed.

The converter-house at the Tooele plant has a single row of five converters extending in a row from north to south, the three converters at the north end, treating copper-matte, delivering the fume to a flue going southward to the new Cottrell treater, whereas the two southern converters, which treat leady matte, blow to a paral-

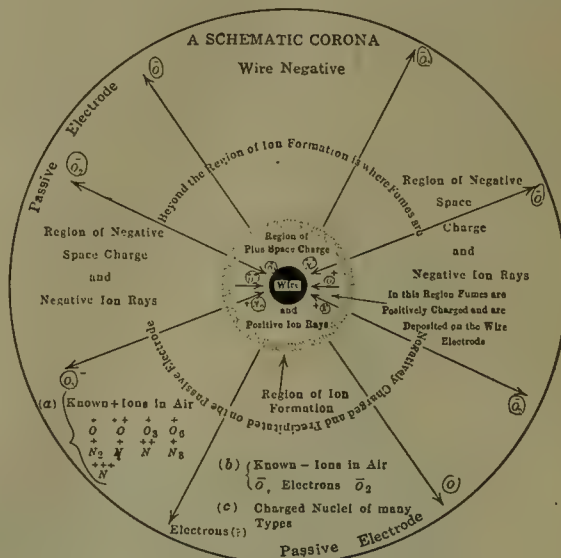

\*Trans. A. I. M. E., Vol. XLIX, 540.

†Trans. A. I. M. E., Vol. XLIX, 579.

lel flue which leads north to the bag-house above mentioned. There is provided a branch pipe from the treater-flue, so that, in case of need, part of its gases can be diverted to the bag-house. The course of the converter gases is by the long bottom flue of 81 sq. ft. cross-sectional area to the distributing flue, thence by two branches to either of the two Cottrell units, each consisting of 110 pipes, upward through these pipes, thence by a down-cast flue of 45 sq. ft. area to a No. 12 Socorro suction-fan, and to the 6-ft. diameter stack. If desired the flow of gases may be by-passed directly to the stack, at the same time shutting off the treaters. Either unit of the Cottrell treater may be cut out from the flow for cleaning or repairing. Just before going to the treater at the distributing flue atomizing water sprays are inserted, by which water is sprayed into the moving gases for the purpose of wetting and cooling them. Cooled they certainly are, but the dust refuses to take up the moisture to any extent, and, when deposited on the treater-pipes, it appears as a bulky, fluffy, dry product, difficult to wet. Through each pipe, from an insulated frame above, an axial wire passes to another frame beneath the pipes. Thus the high-voltage current, of 50,000 to 70,000 v., has to jump across the 6-in. interval between the wire and the inside of the 12-in. pipe. In so doing it drives the dust particles to this inner surface. Here it attaches itself, forming a gradually thickening coating. Some dust also clings to the central wire. During each shift one of the units is cut out by switching off the electric current; the dampers leading to the unit are closed, and, by jarring the pipes, the dust is caused to fall into the hopper-shaped bottom of the unit, where it may be drawn off. The cleaning being completed, the current is turned on and the dampers re-opened to resume operation. The product as obtained is light, fluffy, dry, bulky, and, when withdrawn, is difficult to wet. Due to these qualities it is an unsatisfactory material to treat. It may be either briquetted, or added as one of the ingredients of the charge sent to the Dwight-Lloyd sintering machines.

It will thus be seen that the purpose of the installation is to pass the gases upward through a nest of tubes, each tube taking its share of the total flow. It is during the brief period of upward movement that the work of removing the fume must be done, and it is the phenomena of dust-separation that is now to be considered. At night, looking downward through a tube, one notices a glow, called the aurora, created by the high-tension current. A similar glow may be noticed at the insulators at the towers of a high-tension transmission line, at the poles of a static electric machine, and in the atmospheric phenomenon of the aurora borealis. W. W. Strong, at a recent joint meeting of the American Institute of Mining Engineers and the American Electrical Society, discussed the theoretical aspects of electrical precipitation of fine material, as a result of these observations. and his diagram, which is a cross-section of a tube, merits careful examination. It shows the central wire and the

pipe upon which the deposit is received. Upon passing a positive electric current the gases, oxygen and hydrogen respectively, are ionized, and the negative ions attach themselves to the dust-particles and are driven to the pipe by the electric field. The particles with the positive ions go to the wire from a smaller region of plus space. To clear the deposit on the wire a striking-rod

SCHEMATIC CORONA IN COTTRELL TUBE

is run just below the lower wire-guide bars and just above the weight which stretches the wire. This rod strikes the wire, jarring off its attached load.

The treater is lined with  $\frac{3}{8}$  to  $\frac{1}{2}$ -in. sheets of 'transite,' an asbestos-board made of asbestos and cement, pressed together under heavy pressure. The dampers are 'transite' sheets  $\frac{3}{4}$  in. thick.

SULPHONIC ACIDS are prepared by D. Tyrer in conformity with a patented process in which he first makes the mono-sulphonic acids of benzine and other hydrocarbons, boiling below  $200^{\circ}$ , by passing the vapor of the hydro-carbon through  $\text{H}_2\text{SO}_4$  heated to  $100^{\circ}$ . By this method the  $\text{H}_2\text{O}$  formed is steadily removed from the reaction mass. In the preparation of disulphonic acids, the current of vapor is stopped when a given amount of the mono-sulphonic acid has been formed. More  $\text{H}_2\text{SO}_4$  is added and the temperature is raised to the favorable point. The unsulphonated portion of a hydro-carbon, treated by this method, has been freed from its impurities, notably from sulphur compounds, and can be condensed in a purified form.

TRIPOLI or diatomaceous earth was produced to the extent of 2721 short tons in 1916. The chief centres of production were California, Connecticut, Maryland, Massachusetts, Nevada, New Hampshire, New York, and Washington. The market value of tripoli is about \$9.50 per ton. Large deposits are being developed in Maryland and Virginia.

# Preferential Flotation

By W. SHELLSHEAR

By preferential flotation is meant the separation by flotation of one or more sulphides from each other. It is to be regretted that there is still much confusion of terms in describing flotation work. The American nomenclature which applies to selective flotation, indicating the separation of sulphide minerals from non-sulphide gangue, as distinct from preferential flotation or the separation of one or more sulphides from each other, however, well meets the case, and its adoption should be universal. These terms will need to be modified to some extent to cover the flotation of oxides and carbonates, but these are special cases. It is intended, rather, to deal here with facts gained from experience in operation and conclusions derived therefrom than to attempt to formulate a theory to account for the action of the different processes described.

Although the possibilities of preferential flotation were hinted at by Cattermole and others, it is only in recent years that processes have been devised that have made it a commercially profitable operation. The first of this type, which has proved successful in large-scale operations, was the Horwood process, in which certain sulphides have their surfaces rendered immune to flotation by roasting, leaving the surfaces of other sulphides unaffected. The success of this process largely depends, therefore, on careful attention to the detail of roasting, such as the range of temperature, and the rate of feed. Large-scale operations, however, have demonstrated that, with modern mechanical furnaces, these factors can be kept well under control, and it is difficult to understand why this process is not in use for the treatment of many mixed sulphide ores, especially those containing lead, zinc, and iron.

It had long been recognized in the Broken Hill mills that when ore finely ground to a pulp was subjected to aeration, either by exposure to an air-surface, as in tabling operations, or else by a fall into a spitzkasten, cone, or similar apparatus, the galena and silver sulphide floated more or less imperfectly on this surface in preference to the zinc sulphide. This flotation was undoubtedly due to lubricating oil in the mill-circuit. Samples of the frothy scum from mill dewatering cones assayed in some cases as high as 60% lead, and 50 oz. silver per ton, but in all cases the scum was thin and represented only a small percentage of the sulphides present. Milling experience had thus demonstrated that there were some inherent properties possessed by the sulphide minerals, which were more marked in the cases of the lead and silver sulphides. Advantage was not taken of this fact, however, till Lyster proved that by controlling certain factors in the flotation treatment, use

could be made of the relative differences between the natural properties of the various sulphides to effect their separation from each other. This was the first important step in the evolution of preferential processes. These distinctive properties of the individual sulphides vary somewhat with the different classes of ores. Thus, for example, they are found in a more marked degree in calcitic Broken Hill ores than in the rhodonite or garnet sandstone variety. For this reason, even in apparently similar types of ore in the same locality, working conditions, as far as preferential flotation is concerned, need to be modified and adjusted to suit each particular case.

The controlling factors for preferential flotation of this type are the nature and amount of the agitation, variation in temperature, and proportioning of the medium used, the control of the air-supply during agitation, and the proportion of mineral salts in solution. It is believed by some that the preferential action in processes of this type is due to poor flotation. For instance, one writer, referring to Lyster's process, hints that it is probably due to imperfect conditions, the high grade of the lead being caused by only the finest particles of the lead floating, and that therefore the residues probably are high. This is a mistaken idea as there are large-scale plants working on the Lyster principle, obtaining lead concentrate assaying as high as 60% in that metal while the residues averaged less than 2% lead. The secret of their success is the scientific adjustment of the controlling factors previously mentioned. Although these distinctive physical properties of the sulphides, by reason of which preferential flotation of this type was rendered possible, were present in a rather marked degree in slime freshly crushed from crude ore, it was found that if the slime were allowed to settle and accumulate in dumps these properties were seriously altered. This was probably due to oxidation and to concentration of salts in solution on the surfaces of the sulphides. Especially was this the case if the sulphide particles had dried from exposure, because it was then extremely difficult to obtain preferential flotation at all along these lines. As a rule if a dump-slime is treated on the Lyster principle a poor grade of 'float' is obtained, consisting of mixed lead and zinc sulphides.

It was the continued research in the treatment of dump-products that resulted in a great forward leap in preferential work, the discovery of certain reagents or mediums, which, although used only in small quantities, could temporarily wet, or render incapable of flotation, certain sulphides, leaving the floatable properties of other sulphides unimpaired. It was found possible, by

using these reagents in conjunction with various methods of flotation, to preferentially separate one or more sulphides from each other in an efficient manner, whether these products were freshly crushed or had been stacked in dumps. The fact that these reagents cause only temporary wetting, this effect being more complete when the reagent is still active as a medium in the solution, enables a sharp line of distinction to be drawn between these processes and those of the Horwood type, in which the faces of certain sulphides, such as zinc and iron, are permanently altered by the roasting action, rendering them for the most part permanently incapable of flotation.

Another type of process in which the Horwood effect is produced by chemical means is the ferric-chloride method. The cost of chemical reagents generally makes a process of this type uneconomical.

The action of deadening reagents is extremely difficult to understand, as every medium at present known appears to act in a different way. Under certain conditions in a mixed lead-zinc sulphide-slime sulphuric acid will cause a preferential flotation of lead sulphide. This method was worked for some months as a commercial process treating the Central mine slime-dumps. Sulphuric acid in this case was added to the slime-pulp in the cold, no oil being used, although a certain amount of the soluble constituents from the oil used for the zinc flotation was returned with the circuit-liquor. In most cases the addition of fresh oil disturbed the preferential action. After floating the lead sulphide, using machines of the sub-aeration type, the zinc sulphide was floated by the addition of heat, more acid, and eucalyptus oil. This process is only workable in the case of certain Broken Hill slime. In other cases, under practically similar conditions, a mixed sulphide-float is obtained. Even in a favorable slime the preferential action is upset by an excess of sulphuric acid.

In some cases, when experimenting with this method, one can obtain a float, the upper portion of which consists of lead sulphide and the lower portion of zinc sulphide, one sulphide gradually merging into the other. This process was discovered by Hebbard and Harvey, to whom also is due the successful development on a large scale of the under-driven suction-aeration machine for flotation.

The action of reducing gases, for example, sulphur di-oxide (Bradford's patent), especially if generated in the solution, is entirely different. Sulphur di-oxide when used in treating a mixed sulphide ore deadens each sulphide in succession according to their relative flotation properties. Thus, when treating an ore containing iron, lead, and zinc sulphides by this process, conditions may be so regulated that each sulphide may be floated in succession, the conditions being practically controlled by the amount of sulphur di-oxide gas in the pulp. An excess of sulphur di-oxide will, in most cases, render all the sulphides present temporarily immune to flotation, and in this case the surface will merely be covered by a mass of thin white bubbles. Although a fine adjustment

of conditions is required to float the sulphides in succession as described, in actual practice it is not difficult to float the lead and the iron sulphides as one product, leaving the zinc sulphide in the residue. It is interesting to note that once a sulphide is wetted it is practically impossible to re-float it as long as the sulphur di-oxide gas is in the solution. To float the wetted sulphide, heat and sulphuric acid usually are required. Although this process would appear to be delicate, the working conditions are not difficult to control in a well-designed plant, as proved by the fact that several large-scale plants are working successfully at Broken Hill using a modification of this method.

The action of sulphur di-oxide appears to be unaffected by the nature and amount of the salts in solution, within reasonable limits, and the amount of gas required is usually so small that its chemical action, if any, on the surfaces of the sulphides must be very slight. In some cases, to apply this process, the gas is passed directly into the solution, while in others it is generated therein by the addition of sulphuric acid and certain salts, such as sodium hypo-sulphite.

As another instance of the action of these agents I may take the case of potassium permanganate and potassium bichromate. Both are powerful oxidizing agents, and yet each acts in a different way. Potassium permanganate when added in small quantity to a lead-zinc sulphide slime will wet the zinc sulphide, and, providing conditions are correct, the lead sulphide may be floated as a high-grade product. The addition of sulphuric acid at normal temperature to the lead residue will cause a rapid and practically complete separation of the zinc sulphide from the gangue. This proves that the surfaces of the zinc sulphide are only temporarily affected. An excess of permanganate in the primary treatment will result in both sulphides being deadened and their subsequent flotation is usually difficult, even with heat and sulphuric acid. On a slime of a similar type potassium bichromate will cause a preferential flotation of the zinc sulphide, leaving the lead sulphide in the residue.

With this reagent the conditions required are usually more intense. Thus, in most cases a 0.2 to 0.5% solution of the reagent is required at a temperature of 120° to 140° F., whereas the potassium permanganate works at normal temperatures. In some cases a long digestion of the pulp with potassium bichromate is required to effect the deadening of the lead sulphide. Although this paper deals more particularly with the preferential flotation of lead-zinc sulphides, there are other sulphides which can be preferentially floated with these reagents. Potassium bichromate, for instance, will cause a preferential flotation of copper pyrite from iron pyrite.

In connection with the processes previously mentioned, the term wetting one sulphide in preference to another has been used. This term is employed by Bradford in describing his preferential processes, and as far as one can see, no other term adequately meets the case. When agitating a lead-zinc ore with one of these reagents in a glass vessel maintaining correct conditions, it will be

found that one sulphide will be in a flocculent condition, and the other in separate grains similar to the constituents of the gangue. If the glass vessel with its contained pulp be now connected to a vacuum apparatus, and the air above the surface of the solution be evacuated, gas bubbles will be plainly seen attached to the lead sulphide, but none to the zinc. It therefore seems reasonable to conclude that the function of these agents is to rob one or more of the sulphides of gas, leaving the others with sufficient gas on their surfaces to admit of their subsequent flotation.

The sulphur di-oxide process points to a gradual displacement of gas from the various sulphides in rotation, according to their flotation properties, especially when it is considered that this gas is a powerful reducing agent. Possibly other agents of this class act in the same way.

To obtain a preferential flotation of zinc sulphide, leaving the lead sulphide in the residue, it is obvious that, as the flotation properties of galena are stronger than those of zinc-blende, the preferential agents must act in a different way. It will be found that in almost all cases of preferential lead flotation heat is not required, and only comparatively small quantities of reagents are necessary. This is not the case with the preferential flotation of zinc sulphide, since in all known cases strong solutions and high temperatures are necessary, indicating that a chemical action takes place on the surface of the lead sulphide. Thus the bichromate action is probably due to the formation of lead chromate on the surface of the sulphide, and experiment has proved that in Bradford's salt process a small percentage of lead is in solution as lead chloride. The fact, however, that the lead sulphide can be floated afterward in this process by the use of potassium permanganate and other salts indicates how comparatively slight must be the chemical action. It therefore seems probable that the flotation of any sulphide will be hindered in some degree by the presence in the solution of a salt which will chemically react with it. It was first pointed out in the case of Minerals Separation *v.* Elmore that, if virgin sulphides from certain localities were washed in ether and the ether afterward removed and evaporated, a residue was left consisting of a hydrocarbon oily in nature mixed with free sulphur which could be plainly seen in crystalline form. This has been verified by similar work on Broken Hill sulphides, but it has also been proved that some sulphide ores contain more natural oily residue than others. Whether there is any relation between the percentage of oily residue, the amount of adsorbed gases, and the floatative properties, remains to be proved. Experiments up to the present have indicated that dumps containing a relatively high percentage of this oily residue float more readily than those which do not. From the very small quantity of oil in a frothing agent necessary to produce efficient flotation, it seems possible for the adsorption of gases on the sulphides to be accounted for if merely an infinitesimal trace of oily matter be present in this composition.

Although the principles underlying preferential pro-

cesses are only imperfectly understood, by following routine conditions of working obtained by experiment in the laboratory and on the large-scale processes of this type, they may be made commercially profitable. A scientific control of such factors as rate of feed and its regularity, quantities of reagents, and the like, is, however, vital.

Regularity of feed is essential. To call attention to the importance of this factor would seem unnecessary were it not for the fact that in many cases it is not given sufficient prominence. It is important in all metallurgical operations, but even more so in the case of preferential processes, because, without regularity of conditions, it is not practicable in many cases to work these methods at all. One must aim at getting feed and conditions of mechanical running as perfect as possible, the main axiom of all flotation-work being that without smooth running the accurate adjustment of metallurgical conditions is virtually impossible. In working a plant for the treatment of a mixed lead-zinc ore preferentially, irregular conditions will spoil both the lead and the zinc products, and neither will be of marketable value.

Control of aeration is also vital. Bradford was the first to discover that aeration could be controlled by a valve on the suction-pipe of a centrifugal pump, the air thus sucked in being atomized by the action of the impeller. Owen's patent shows a further development of this principle, the aeration in this case being controlled by a pipe connected to the bottom of an ordinary agitating vessel, the required air being sucked in and atomized by the agitator. It was found that by working on these lines the ordinary spitz-box used in the Hoover machine was unnecessary, the aeration and flotation being conducted continuously from the bottom and top of the same machine. In this type of flotation-machine there are three distinct zones of action: (a) the aeration-zone, where air is sucked in by the impeller; (b) the atomizing-zone, where the air is completely broken up by the aid of baffles which also check the rotary motion of the liquid; and (c) the flotation-zone, a still zone on the top of the vessel where the flotation takes place. Similar control of aeration may be effected on either of these machines by replacing atmospheric air with air under pressure.

In considering the action of frothing-agents it must be said that it has now been definitely proved that, to float certain sulphides, oil, in the sense of an organic agent of any description, is unnecessary. Thus, when preferentially floating galena by the sulphur di-oxide process no oil or organic agent as a general rule is required. There is at the present time a commercial plant giving a high recovery of lead with this process without the use of any medium of this description. In some cases oils or organic frothing-agents have been replaced by soluble inorganic frothing-agents, such as sodium carbonate. The function of the frothing-agents in most flotation processes is to intensify the physical conditions which promote flotation rather than to produce them. When experimenting with a mixed sulphide ore with a preferen-

tial agent, if a strong stream of atomized air be passed through the agitated pulp, the color of the sulphide which will float will be seen in the froth as it breaks at the surface of the solution before any oil or frothing-agent has been added at all. In the cases of most preferential processes the addition of certain unsuitable oils or frothing-agents will completely nullify the preferential action. For instance, the mixing of the pulp with an exceedingly small amount of oils of the wrong type before the addition of the preferential reagent will generally result in no separation of the sulphide minerals whatever. It is extremely difficult to separate two or more sulphides which have been floated with oil as a mixed concentrate in a previous operation, although this can be done with a process where intense conditions are used, as in Bradford's salt-process.

Although, as previously stated, the action of frothing-agents is to intensify the conditions of flotation, one of the many problems of preferential flotation is to use oils which will assist the flotation without disturbing the preferential action. As an example of a preferential process in which oil is not used, the sodium carbonate process may be taken. Freeman discovered that by treating mixed lead-zinc sulphide slime with sodium-carbonate solution varying in strength from 1 to 10%, according to the ore treated, employing an iron vessel with ordinary conditions of agitation and aeration, the lead sulphide floated preferentially. The sodium carbonate in this process serves a double purpose, being a preferential reagent and at the same time a soluble frothing-agent. The addition of any oil is generally deleterious to the successful working of the process, but in any case it is unnecessary, as the sodium carbonate usually gives a firm coherent froth. Although this process works quite successfully at normal temperatures, the grade of the lead concentrate is not affected by heating the solution up to 120°F. In a copper machine, on the other hand, sodium carbonate has a quite different action, for, if the temperature of the solution be raised to 160°F., a preferential flotation of zinc sulphide is obtained, leaving the lead sulphide in the residue. Even at normal temperatures the preferential flotation of the lead is imperfect if any copper is present as a part of the treatment-machine.

This is due to the fact that flotation conditions as a rule are materially altered if there is present in the solution even a trace of metallic salt such as a salt of copper, or mercury. If quantities of these reagents up to 2 or 3 lb. per ton be added to a pulp containing zinc sulphide or a sulphide of a similar nature, and the pulp be subjected to flotation-treatment, after flotation has taken place there is usually no trace of copper present in the solution. From this fact one is led to the conclusion that the action of these metallic salts is similar to the action of copper sulphate on scrap iron, or, in other words, that the sulphides become coated with metallic copper or mercury, as the case may be. Bradford was the first to discover the properties of these metallic salts, and in 1913 he patented the use of reagents such as cop-

per sulphate to exalt the flotation effect. Another interesting example of the action of copper salts is afforded by Bradford's salt-process. As is well known, this process consists in agitating a mixed lead-zinc ore with sulphuric acid in a salt solution varying from 7 to 10%, and heating the solution to about 140°F. The zinc sulphide floats preferentially, leaving the lead sulphide in the residue. After the zinc sulphide has been floated off, the lead sulphide may be floated by the addition of copper sulphate to the solution used for the flotation of the zinc, this being practically a continuous process. There seems to be large scope for this process, as it makes an extremely clean zinc concentrate, and yields a high recovery of zinc.

Different processes require different machines to obtain the best results, and it is only by experiment on any particular ore that the best type of machine in any case can be determined. For instance, Bradford's salt-process will work successfully in the ordinary Hoover machine, whereas processes of the Lyster type usually work to advantage in the combination of pump and spitz-box machine illustrated in Lyster's patent. Permanganate of potash and agents of this type work to the best advantage in a sub-aeration machine, but they will give good results in the ordinary Minerals Separation apparatus. Every type of machine, however, usually requires different quantities of reagents and different conditions. Although I have not seen the Callow machine tried in this particular class of work, it seems to be suited for a number of these processes, and there is no reason why it should not work successfully. The action of metallic salts clearly demonstrates that the metal used in these machines, especially in laboratory machines since commercial machines are usually made of iron or wood, is important, and for consistent results the laboratory machine must approximate the large-scale apparatus in its details.

As in ordinary flotation so in preferential treatment in order to obtain good results two distinct phases are necessary. First, the pulp is brought into a physical condition for efficient flotation, and, second, aeration takes place, enabling the sulphide-mineral that is to be floated to be separated as a froth. In the first place conditions are to be so adjusted that the mineral to be floated shall assume a clotted form, or, in other words, bound together in minute masses in the pulp. This clotted appearance is due to formation of primary gas-nuclei, and only under certain conditions will these nuclei form. If this primary phase is incomplete, aeration will cause a thin froth which is troublesome to handle and the recovery will be low.

In preferential flotation when deadening one sulphide the other, if conditions are correct, will be in a clotted condition. If aeration be now applied an efficient flotation will take place. If, however, physical conditions are such that the action of the preferential reagent is imperfect, no amount of aeration will give good results, regardless of the manner in which it is applied.

The action of oil or frothing-agents appears to be

mainly to increase the size and maintain the stability of the primary nuclei already referred to.

Every ore appears to have distinctive physical properties as far as its floatability is concerned, and consequently the method of treatment of two different ores is rarely the same. This is particularly the case with lead-zinc sulphide ores. The varying composition of zinc-blendes from various localities to a large extent accounts for this. The properties of blende, as far as flotation is concerned, appear to be influenced by the amount of iron in its composition. Thus the zinc-iron blende, marmatite, having an approximate composition of  $5\text{ZnS} \cdot \text{FeS}$ , has quite different properties from a true 'resin blende' of the composition  $\text{ZnS}$ , and even resin blendes differ to some extent in their properties. It is obvious, therefore, why one preferential process will work successfully on one class of sulphide ore and fail on an ore of a similar type. This has been previously illustrated in the case of the sulphuric-acid process, and other examples might be cited. Silver sulphide follows lead sulphide so closely in milling operations that for a time it was believed that the two sulphides were in chemical combination. Flotation has absolutely disproved this, since different preferential processes will in many cases give the same grade of lead concentrate from the same ore, but the concentrate will in some cases be high in silver and in others low. Indications show that silver sulphide is one of the most easily floated of all sulphides. The sulphur di-oxide process seems to be peculiarly adapted to the flotation of silver, and in many cases on obtaining a lead concentrate preferentially by this process the recovery of the silver is higher than that of the lead.

Preferential flotation is yet in its infancy, but most of the processes mentioned have worked or are in operation on a large scale and are not merely laboratory conceptions.

To test an ore for this class of flotation requires a great deal of experience and observation, as there are so many variable factors involved, and the disregard of minor details will usually affect the success of the treatment seriously. Preferential flotation has come to stay, and there are many fine-grained complex ores which can be made commercially profitable by these methods. Mixtures of zinc and iron sulphides, fine-grained lead and zinc sulphides, and other ores of this type, are practically dependent on these processes for commercial separation. The scope for preferential flotation is, therefore, a large one, and these methods will soon be quite universally adopted.

DOUBLE ACID-PHOSPHATE is a new product evolved by the Bureau of Soils of the Agricultural Department. The object is to provide a richer fertilizer, thus reducing the consumption of sulphuric acid direct. Phosphoric acid is obtained by electric smelting of phosphate rock, and more raw phosphate rock is treated with this, giving a compound containing 45% available phosphoric acid as against 16% in the super-phosphate of commerce.

## Manganese in Furnace Slags

\*In the production of certain alloy steels the effect of superheating the working slags results in the separating of the most readily reduced slag constituent. Thus in making manganese-steel in the open-hearth furnace the primary slag covering the molten pig-iron charge was a rich ferrous slag of the composition approximately  $\text{FeO} \cdot \text{Fe}_2\text{O}_3 = 80\%$ , and  $\text{SiO}_2 = 20\%$ , fusible at about  $1300^\circ\text{C}$ . Into this a pyrolusite ore containing

	%
$\text{MnO}_2$ .....	85
$\text{CaO} + \text{MgO}$ .....	5
$\text{SiO}_2$ .....	10

was gradually added. The  $\text{MnO}_2$  becomes  $\text{MnO}$  on superheating, the  $\text{FeO}$  being changed to  $\text{Fe}_2\text{O}_3$  by the oxygen liberated from the  $\text{MnO}_2$ . It was then found that the  $\text{FeO}$  and  $\text{Fe}_2\text{O}_3$  in the slag, if increased by further additions of 'hematite ore' (manganese) and lime, caused a rapid reduction of the manganese from the slag, manganese entering the liquid metal. When the slag contained over 50% manganese that element entered the metal, whereas if the slag was adjusted so as to contain above 50% iron, then iron was reduced from the slag in preference to manganese. The slags higher in  $\text{MnO}$  were more fluid than the rich  $\text{FeO}$  slags, and were apparently fusible at a lower temperature.

The refining of alloys may be illustrated in the case of the elimination of manganese in the puddling or open-hearth steel processes. Thus the reaction between the slag constituent  $\text{FeO} \cdot \text{Fe}_2\text{O}_3$  and the alloy constituent  $\text{Mn}_3\text{C}$  in the pig-iron is of the type:

Manganous oxide displaces the iron oxides in the slag, the manganese in the pig-iron being replaced by pure iron from the reduction of the iron oxides. Superheating the slag renders the  $\text{FeO} \cdot \text{Fe}_2\text{O}_3$  more active, while that of the molten pig-iron increases the instability of the  $\text{Mn}_3\text{C}$ ;  $\text{CO}$  gas is liberated; and the slag is enriched by the entrance of  $\text{MnO}$  at the cost of the iron oxides  $\text{FeO} \cdot \text{Fe}_2\text{O}_3$ . In such actions the active oxides  $\text{FeO} \cdot \text{Fe}_2\text{O}_3$  are the reducing agents. They are least stable and hence in the condition to react with the other unstable compounds present when by superheat their stability is decreased. Possibly at the moment of exchange it is the ferrous oxide which reacts with the  $\text{Mn}_3\text{C}$  in a reversible relation, thus:

Superheating the  $\text{FeO}$  in an oxidizing atmosphere leads to the formation of  $\text{Fe}_2\text{O}_3$ . On the other hand, liquid  $\text{Fe}_2\text{O}_3$  in contact with molten iron-alloys is readily converted to  $\text{FeO}$  providing a reducing or neutral atmosphere is maintained in the working chamber.

TUNGSTEN is being found in quantities in Rhodesia that promise an important development of the industry.

\*Abstract: Paper by J. E. Fletcher, 'Superheating of Slags.' Soc. Chem. Ind. Birmingham, England.

# Japanese Copper Production

By KENZO IKEDA

The Japanese copper output last year was about 90,000 avoirdupois tons, mainly produced in the form of electrolytic refined copper. The important smelting works and their contribution of metals are as follows:

Smelter and company	Copper production, tons	Annual capacity of blast-furnace, tons
Hitachi, Kuhara .....	17,000	400,000
Ashio, Furukawa .....	16,000	120,000
Besshi, Sumitomo .....	11,000	250,000
Kosaka, Fujita .....	10,000	400,000
Inujima, Fujita .....	4,000	100,000
Abeshiro .....	4,000	.....
Ikuno .....	3,500	.....
Osaruzawa .....	3,000	.....
Ogoya .....	2,500	.....
Others .....	10,000	.....
	90,000	

The amount of copper mentioned above is produced from copper deposits which may be classified into the following four groups:

1. Fissure-filling deposits, or true veins, the majority being in Tertiary rocks and the mineralization caused by circulating solutions, represented by the Ashio mines. The largest known vein is 3000 ft. long, averaging two feet wide, and is 3000 ft. deep, occurring mainly in a liparite intrusive through Paleozoic slate, sandstone, and quartzite. The ores are composed of rich copper pyrite in a silicious gangue.

2. Pyritic bedded deposits in crystalline schists or Paleozoic rocks, such as the Besshi mines, the rocks being chloritic, graphitic, and Piedmontite schists. The deposits consist of pyrite and some magnetite, the copper content being 3.5%. The largest lode explored up to the present time is 500 ft. long, 4 ft. wide, and 3000 ft. deep, the dip being nearly 49°. The form is nearly that of a sheet.

3. Complex sulphide deposits, or simple metasomatic replacements in Tertiary sedimentaries, but with no limestone beds, and in volcanic rocks, this class being represented by the Kosaka mines. The country rocks are liparite dikes and prophyllitic andesite intrusives through liparite tuffs. The orebody is 1600 ft. long, 400 ft. in maximum width, and 400 ft. deep, massive in form, with ores of three kinds, namely, pyritic or yellow ores, complex sulphides or black ores, and those with a quartz gangue, called silicious ores, the average mixture having 2% copper, 20% iron, 20% sulphur, not taking into account the sulphur contained in baryte, 22% SiO<sub>2</sub>, 20% baryte, 6% zinc, and 1.3% lead, carrying some silver and gold. The mines are being worked by open-cut chiefly.

4. Metamorphosed metasomatic deposits, or so-called contact-deposits, in Archean, Paleozoic (mainly), Mesozoic beds, or older sedimentaries, and rather acidic plu-

tonic rocks, as seen at the Kamaishi mines. The form and size are very irregular as compared with the other groups, and they are confined mainly to the margins between the Paleozoic clay-slates and limestones, and the intrusive granites and diorites. The copper deposit is associated with large adjacent accumulations of magnetite ore, so that the mine produces material that is treated for its iron as well as for copper.

These four classes of copper deposits are in different zones, each having characteristic features, so that usually it is possible to tell to what class a certain orebody in a district belongs, and, moreover, a fair conclusion may be hazarded from previous study and experience as to what extent it may be possible to develop the mines. More than 90% of the total copper output, considered as to its origin, is distributed as follows:

	%
From fissure-filling deposits .....	50
" bedded deposits .....	30
" metasomatic deposits .....	14
" contact-deposits .....	6

The remaining 10% of the copper production comes from miscellaneous ore deposits.

The methods of treatment followed are in outline as follows: Ores from fissure-filling and contact-deposits are subjected to concentration and are then smelted in blast-furnaces by semi-pyritic smelting. The coke on the charge is from some 8 to 16%.

Ores from bedded, as well as from metasomatic deposits are usually smelted direct in blast-furnaces by pyritic smelting. The coke consumed amounts to about 2 to 5%. The blast-pressure employed is 1.5 lb. per sq. in. as a maximum, but generally is kept close to 1 lb. The ash-content in the coke is from 20 to 25%. The ores treated in these smelters are obtained chiefly from mines belonging to the same company.

I may cite another example of a pyritic smelter, namely, the Inujima, which was recently designed by myself. The smelter consists of one blast-furnace 180 in. long for matting the ore, another furnace 110 in. long for matte concentration, and 14 Mabuki hearths for making blister copper. The smelter is for treating custom ores only, the charges being composed of a mixture of nearly 40 different kinds and sizes of ore. The blast-pressure is about 0.8 lb. per sq. in., and the amount of blast supplied per minute is about 500 cu. ft. of free air for each foot in length of the hearth. No coke is used in the normal charge, but coal fed at the tuyeres as auxiliary fuel amounts to about 3%. The average copper-tenor is nearly 2.6%, the amount of fine in the charge being 35%. This is subjected to a preliminary stamp-briquetting, or to pot-roasting, according to the nature and degree of fineness. The Mabuki hearth may be called a Japanese copper converter. It is rather primitive, and is very simple in construction, but it requires some well-trained workmen. In addition to the furnaces in regular daily operation in this plant there is a spare 160-in. blast-furnace and six extra Mabuki hearths.

# REVIEW OF MINING

## LEADVILLE, COLORADO

DEVELOPMENT AT BIG EVANS.—DOWN TOWN MINES.—HILL TOP.

The discovery of an extensive shoot of low-grade sulphide ore on Prospect mountain has disclosed many important geological facts and has opened the way for intelligent development. In a cross-cut that is being driven from the 300-ft. level of the Silver Spoon shaft, in Big Evans gulch, north, under Prospect mountain, Warren F. Page, manager for the Luema Mining Co., has cut an extensive ore-shoot. The cross-cut has penetrated it for 120 ft. and is still in ore. The shoot occurs in the big Monarch fault-fissure, which has been identified with all the important orebodies in the Big Evans district, and is believed to extend to the west from the fault on the white-lime contact. This has not been determined to date, as no development, other than advancing the breast, has been done. The ore is stated to be a low-grade sulphide of a character entirely new to the Big Evans area. It carries gold, silver, and lead. Small bunches of extremely high-grade lead-silver ore have been found in the deposit, indicating that larger shoots of the rich ore will be found as development proceeds. The greatest importance attached to the discovery at this time is the fact that it proves the continuation of the regular Leadville formations under Prospect mountain. Following the theory of the pioneers, mining men have regarded Prospect mountain as a barren territory and have believed that the ore-bearing formations of the district extended no farther north than Big Evans gulch. This theory has now been exploded. The presence of ore on the white-lime contact proves that conditions in this area will be similar to those on Iron and Breece hills, and opens to development a territory greater in area than both of them. Ore has now been found in the upper and lower contacts of Prospect mountain. Last year, Mr. Page completed the Valley tunnel 1600 ft. into the mountain, and cut an immense body of iron oxide near the breast. A winze put down a depth of 100 ft. at this point remained in ore throughout. The conditions found made it impracticable to operate through the tunnel, and early last spring the driving of the cross-cut from the Silver Spoon shaft was started to get under this deposit. Although driving proceeded along the big Monarch fault, the cutting of ore before nearing the shoot opened above was not expected. The sulphide deposit was encountered a distance of 600 ft. north from the shaft.—Mr. Page states that the breast will be pushed ahead until reaching a point under the winzes, regardless of what conditions are found. Then cross-cuts and raises will be driven into the orebody to determine its extent and value.

A new leasing company with M. M. McGinnis, a well-known Leadville mining man, as manager, has secured a sub-lease from the Down Town Mines Co., on the P. O. S. property on Carbonate hill. Work is now under way repairing the surface buildings and installing machinery. The P. O. S. is one of the properties in the Down Town area, just south of the Penrose. It is believed to be rich in silver-bearing iron and manganese ore. The property, at one time a heavy producer of iron and silver, has been idle for twenty years.—The A. V. shaft, near the old Harrison reduction plant in California gulch, is to be re-opened by a company of Leadville mining men that has secured a lease on the property. The

shaft is now being examined and plans completed for erecting hoisting and pumping machinery. The A. V. is in the iron and manganese zone that extends west from the Carbonate property through the P. O. S., Bon Air, Bohn, and Home Extension, and at one time was an extensive producer. The present lessees hope to discover large bodies of high-grade manganese ore.

C. H. Weaver, of Toledo, Ohio, who for some time was associated with the late W. B. Anderson in operating the Anderson adit near Birdseye, has organized a company of Eastern capitalists for the purpose of developing several properties in the Leadville district. The company has purchased the Anderson adit and has changed its name to the Ohio. Operations have been resumed and a contract to drive the main adit 1000 ft. has been let. The adit is now 1700 ft. long, following a south-easterly course through Prospect mountain toward Leadville. This distance is almost entirely in the Webber grit with a few porphyry dikes. The addition of the 100 ft. is expected to bring the breast through the grit and blue lime and into the first contact. The recent discovery of ore through development carried on by Warren F. Page at the Silver Spoon shaft adds materially to the prospects of the Ohio project. Mr. Page's cross-cut is following a course a little west of north and at a greater depth than that attained by the Ohio adit, but if continued far enough the two projects will cross each other. Ore has been found by Mr. Page both in the blue-lime and the white-lime contacts, proving that these formations continue into Prospect mountain. A slight rise in the formations beyond the Page ground will bring the ore-zones directly in the path of the Ohio project. Both of these enterprises are of great importance to the Leadville district and are being closely followed by local mining men.

Mr. Weaver and associates have also secured a lease and bond on the old Hill Top property in Park county, just over the range from Iowa gulch. Plans have been completed for extensively prospecting the property by means of a diamond-drill in the hope of discovering a lower contact or any parallel ore-shoots which may exist beyond the big vein that for years made the Hill Top a famous producer of lead and silver ore. Bodies of marketable low-grade ore are also expected to be found in the old workings. Supplies for the winter are now being brought in.

## COLORADO SPRINGS, COLORADO

CREEDE EXPLORATION CO.—WAGON WHEEL GAP FLUORSPAR MINE.

Things are livelier at Creede than they have been in many years. The increased prices of silver and lead have been partly responsible for this, but the advent of the Creede Exploration Co., a subsidiary of the American Smelting & Refining Co., which has a lease on practically all the ground on the Amethyst vein below the level of the Wooster adit as well as some of the Commodore mine above that level, has had more to do with the increased activity than anything else. This company is now unwatering the Amethyst shaft below the adit-level and expects to start unwatering the Commodore shaft as soon as the necessary machinery can be obtained, which will be within the next 30 days. As soon as these shafts are unwatered and the necessary development work can

be done, the extraction of the ore below the adit will be begun. The company has built a power-house near the Humphreys mill which will supply power for the Commodore workings. The power for the Amethyst shaft comes from the city plant at Creede.—The Mineral County M. & M. Co. is mining a little ore from the Happy Thought ground, which is being treated in the Humphreys mill.—The Del Monte & Chance Mining Co. is operating the Last Chance-Del Monte-New York property from which about 300 tons per month is shipped.—The lessees on the Bachelor are shipping about 500 tons per month.—Collins & Co. are said to have opened up a large body of ore of good grade on the Quintette at Sunnyside. They have already started shipping.—The smelters have refused to receive more than a limited quantity of low-grade ore, which has greatly restricted the output of the district.—The fluorspar mine at Wagon Wheel Gap is producing 1500 or 2000 tons per month. About 40 men are employed at present and more will be put on as soon as additional bunk-houses can be built. A track has been built from the lower terminal of the tramway to the railroad, a distance of nearly two miles, and the spar is hauled in cars of 3000 lb. capacity by horses and dumped into the railroad cars; a great improvement over wagon haulage. An air-compressor is being erected at the mine. The underground development has been very satisfactory. The vein is over 20 ft. wide in some places. This mine was opened primarily to supply flux for the Colorado Fuel & Iron Co.'s plant at Pueblo, but the product is now being shipped to steel works all over the country and some, under a guarantee of 98% purity, to chemical works.

### MAYER, ARIZONA

ARIZONA BINGHAMPTON.—BLACK CANYON.—BIG LEDGE COPPER.

The output of the Arizona Binghampton mine, east of Mayer, is steadily increasing. The first six days of October showed a daily output from the flotation mill of 12,500 lb. of copper in a concentrate averaging between 25 and 27% copper. The mill-head averages 4% copper. On this basis, the output of the company for this month will be better than 375,000 lb. of copper. The management announces that at the 500-ft. level an extension of the main orebody from the 400-ft. level has been cut, showing 25 ft. of 9% and 15 ft. of 3% copper. The new strike was made in a raise from the 600-ft. level. It is expected that this same orebody will be broken into at any time on the 600. This strike of ore is considered to be one of the most important ever made in the Mayer district, as it proves another portion of the great Jerome belt.—On the adjoining property, owned by the Copper Queen Co. under the management of Claude Ferguson, a good sized vein of low-grade copper ore has been found 200 ft. below adit No. 2 in a cross-cut run from this winze. Extensive development work is in progress in this property.—The Half Moon Co. has added a gasoline-hoist on the shaft on the next property south of the Copper Queen and Arizona Binghampton. This shaft is to be sunk 500 ft. A number of strong copper veins outcrop here.—Ore is expected at any time in the adit being driven by the Red Metal Mining Co. The property is being developed by Bisbee capital. The adit is being driven to strike a known vein that has been opened by a shaft.—Thorough testing of the ore of the Pocahontas mine is being made with a view to building a flotation mill. The mine is two miles from Mayer. The company has recently been financed by Eastern capital through the president, W. H. Skinner.

The Black Canyon Mining Co. is opening a large body of silver-lead ore in a property four miles south of Turkey station. A drift has been run on a vein that shows 500 ft. of continuous ore, 12 ft. wide at the face. Kansas City capital is interested.—A deal has been closed recently by Bisbee investors for a copper property 12 miles south of Mayer. The

ground was owned by J. L. Dillon and associates. The property is to be extensively developed by an adit.

Anderson and Birch, owners of a silver-lead mine one mile west of Humboldt, shipped a carload of high-grade silver ore this week. A flotation mill with a capacity of 75 tons per day is treating \$15 ore. The Silver Belt company on the north is developing an extension of the same orebody.

Work is to be resumed within a few days on all the properties of the Big Ledge Copper Co. The officials of the company will arrive from Duluth. The size of the orebody recently found in the Butternut at the 425-ft. level, is increasing. The grade continues at 8% copper. The company's smelter is to be completed by the first of the year. By then the company expects to have its two principal mines, the Butternut and Henrietta, opened sufficiently to run its smelter at full capacity.

### MAMMOTH, UTAH

BIG INDIAN.—UNITED TINTIC.—EMPIRE.—MARSHALL LAKE

Mammoth mine has paid the following dividends this year: May 12, 5c., or \$20,000; May 29, 25c., of \$100,000; June 29, 25c., or \$100,000; August 29, 25c. or \$100,000. The dividend paid on October 12, of 10c., will bring the total this year up to 90c. per share, or \$360,000, making the grand total to date \$2,780,000.

The copper-reduction mill at Big Indian is now ready to commence operations. The ore-bins are full. During the past week practically every piece of machinery in the mill has been tested and found to be in satisfactory condition. The copper-solution tanks are being steamed and are already watertight. Preston G. Peterson, secretary and manager for the Big Indian company, who is at the camp, stated that he believes the mill may be producing copper by October 15, that all the machinery will be properly adjusted, and the preliminary troubles overcome. Sulphur for the manufacture of acid is being freighted to Big Indian, and ample supply is already on hand. At first 100 tons of ore per day will be milled, but when everything is running smoothly the plant will be operated at capacity, namely, 300 tons. Fifty feet of work will give the Tintic Standard company a connection between the new shaft and the old workings. This connection will mean much to the Standard, giving better ventilation of the workings and more economical ore extraction. This week the Tintic Standard will send out about six cars of ore.—George H. Dern, manager for the company at Silver City, met with an accident while driving his auto near Hailey, Idaho, last week, and broke three ribs.

A meeting has been called at Salt Lake City for the stockholders of the United Tintic Mines Co. to consider the consolidation with the South Standard Mining Co. It has been suggested that the properties of the two companies be consolidated either by increasing the capital stock of the South Standard to 1,300,000 shares at 10c. par value, or by forming a new corporation with capital stock of 1,300,000 shares at 10c. par value. In case the first method of re-organization is favored one share of South Standard will be issued for two shares of the United Tintic Mines Co., and the balance of the stock placed in the treasury.—The Iron King Consolidated Mining Co., C. E. Loose, president, Preston G. Peterson, secretary, has filed amended articles of incorporation with the clerk of Utah county. The amendment increases the capital stock from 1,000,000 to 2,000,000 shares of the par value of \$1 each. Of this, 1,000,000 shares have been subscribed to the original incorporators and other stockholders, and 1,000,000 shares will be placed in the treasury to be disposed of by the directors for working capital.

Good progress is being made in the development of the Empire mines, at Mammoth. Two cross-cuts are being driven by the Walter Fitch Jr. contracting company, one toward the

eastern portion of the property at a depth of 1800 ft., and the other toward the west at 1500 ft.—Driving is still in progress on the 2000-ft. level of the Colorado Consolidated mine, and it is understood that the management is preparing to sink on the fissure which has been followed for some distance on this level. Aside from this work there is the usual amount of leasing being done in the Colorado mine.

A gold brick weighing 122 lb. and worth \$24,424 was shipped recently by L. T. Holte, from his mine in the Marshall Lake district, 58 miles north of McCall. This brick represents the clean-up for one month. Mr. Holte bought this mine in November 1915; since then it has produced \$300,000 in gold, and during the present year at the rate of \$1000 per day. For the month of August Mr. Holte cleaned up \$60,000. The mill has a daily capacity of 40 tons. From 40 to 60 men are employed.

### WILLOW CREEK, ALASKA

RAE-WALLACE.—GOLD CORD.—FERN AND GOODELL.

Most of the promising prospects and mines are on the tops of rugged sharp mountains, and transportation of the ore to the reduction works is by aerial tramways. Weathering goes on rapidly and slides change the face of the hills and uncover new outcrops daily; talus slides make it necessary in many places to run in open-cuts to expose the formation, but the district as a whole is one where ore is present everywhere. The wagon-road from the railroad-town of Wassile, over which all supplies must come to this district, is being patched up again this year and, while such work is not of a permanent character, it improves conditions considerably. It is to be hoped that the Alaska Road Commission will give this district more attention, so that it will not cost the operators all they make to get in supplies and machinery. Willow Creek has produced more than \$3,000,000 and has paid from the surface. Freight costs \$80 to \$100 per ton from Seattle, and over the so-called wagon road \$2.75 per 100 lb., making the cost of getting materials almost as much as if the district were 100, instead of only 16 miles from a railroad. High-grade ore, which local miners call a telluride, has been found in a number of places on the Fishhook creek. A grab-sample of the ore found on the Rae-Wallace property gave \$1800 per ton, and arrangements have been made to ship out 150 sacks. This property was purchased early in the season from William Martin for \$10,000, and from the present outlook the purchase price will soon be won from the ground.—Four miles below the camps now in operation the country grades out to large flats and rolling hills, heavily timbered, and it is only a question of time until a large central plant will be erected to work all the properties through a long tunnel, doing away with the present excessive mining costs. Ample power can be secured from the Little Susitna river and, with mine-timber near, it will be an ideal location. At the present time all ore assaying less than \$20 per ton is discarded. As no suitable timber is found near the mines, it must be brought up early in the year over the snow or on wagons later. A large tonnage can be secured from this district if mined by modern methods, but as long as the present high cost of transportation over the road and railroad to Wassile pertains, the goberning of high-grade will continue.—The adit of the Gold Cord company, where \$640 ore was discovered last year, has been advanced 175 ft., showing an orebody 9 ft. between walls, which averages \$35 per ton. The gold occurs finely disseminated through a blue quartz.

This vein has been traced over the mountain for nearly a mile, and miners on the other side, on the Archangle creek, claim that they have the northern extension. A 2350-ft. aerial tramway has been erected; the ore is run to the Independence mill for treatment. A mill will be built next year. The owners are Charles Horning, Charles Bartholf, the Isaac brothers, and Byron Bartholf.—The property adjoining the Gold Cord on the south is owned by Kemp and Bartholf, and five strong veins, averaging \$72 per ton, have been developed by open cuts.—The Brooklyn claims, owned by Milo Kelly and associates in Fishhook creek, has shown up well; the main vein is a continuation of the Independence.—William Martin of the Alaska Free Gold Mining Co. has had a successful season, despite the labor troubles brought on by I. W. W. agitators, which forced a close-down early in the year. A vein of good ore has been discovered behind the present mill.

The Independence Mining Co. has done only development work this year, and, as it should be one of the biggest producers in the section, the output for the district will suffer. High-grade ore has been found in many places.

The Rae-Wallace company, which has a bond on the Sky-line group, is developing the mine and erecting a 50-ton Gib-

INDEPENDENCE MINE, WILLOW CREEK

son mill. A 1600-ft. aerial tramway will be necessary to bring the ore down from the mine. A mill, bunk-house, and assay-office will be built during the winter. The main vein is near the top of the mountains directly above the mill-site. The ore is free-milling and carries \$35 per ton. The original discovery of high-grade was a 4-in. vein, but, in stripping this, four more parallel veins were uncovered, running from \$1800 to \$5000. From the general pitch and strike of this, it is thought by many to be a continuation of the Mabel vein. This venture is backed by Wallace, Idaho, capitalists.

At the Fern and Goodell, at the head of Archangle creek, a 100-ft. adit exposes a strong vein. The ore averages \$15. At the surface this ore was a free-milling white quartz but changed with depth to a blue sulphide ore.—Adjoining the Fern and Goodell property on the south is the Talkeetna mine. Though little development work has been done, a mill and aerial tram have been built, and a five-hour run produced 48 oz. A Denver quartz mill was erected and power secured from a 4-ft. Pelton wheel under 50-ft. head. The mine, however, is not sufficiently developed to keep the mill running more than a few hours per week.—The impression prevails at Willow Creek that the schist contact on the north of the district was of no value, but some unknown prospector brought in one this season from this section that has considerable free gold.—The Mable mine has had a successful year's run

and the striking of high-grade this year makes this one of the best little producers in the country. A Denver mill is in operation on this property; aerial tramways bring ore from the mine.—Molybdenite has been found in many places, but no development work has been done.

## COBALT, ONTARIO

NIPISSING.—MCKINLEY-DARRAGH.—KIRKLAND LAKE.

During the first week of October, 11 Cobalt companies together shipped 29 cars, containing 2,184,919 lb. of ore. This is by far the highest record this year, and, in fact, is the first time in recent years that the aggregate has amounted to more than 2,000,000 lb. during a single week. The total shipment during September was 63 cars, containing 4,600,082 lb., thus leading by a considerable margin all preceding months of the current year.—The monthly report of development at the Nipissing mine by Hugh Park, manager, states that during September the company mined ore of an estimated value of \$349,258. The total ore mined from the Nipissing during the nine months ended September 30 amounts to \$2,406,541. No new veins were found during the month, but all stopes continued to produce satisfactorily, and nearly all of the ore-shoots are extending their previously known limits.—McKinley-Darragh is in a strong financial position according to a statement sent out with the last dividend checks. Cash in bank amounts to \$180,687.96 and ore in transit and at smelter amounts to \$98,700. This with ore at the mine ready for shipment brings the total to \$392,887. Dividends paid by this company equal 229% of its issued capital. The new oil-fotation plant will be completed by the end of this month.

The Mining Corporation of Canada is producing at the rate of 5,000,000 oz. per year and by the end of the current year will have 28,000,000 oz. to its credit. The company has acquired control of the old Waldman property and preparations for development are being made.

In the gold camps the spirit of optimism is running high, and the declaration of peace in Europe will spell for Porcupine and for Kirkland Lake the beginning of an era of prosperity that will eclipse all past records in the annals of precious-metal mining in northern Ontario. The amount of ore-reserves at the various mines is estimated at \$80,000,000.

In the Kirkland Lake area, the Tough-Oakes and the Teck-Hughes are operating their mills at full capacity. The mill at the Lake Shore mine will be completed by January, adding to this camp. The Kirkland Lake Gold Mines, which is owned by the Beaver Consolidated of Cobalt, will also soon have a mill, excavation for the foundations having already commenced. Owing to defective machinery, underground operations at the Wright-Hargreaves mine have been suspended; 10 men are employed on surface making foundations for a new and more powerful plant.

## MADRID, SPAIN

FUEL COMMISSION APPOINTED.—GUADALCANAL COAL.

The reform in administration of the mining department of the Government has been productive of excellent results. Explorations for copper and lead are active in many provinces where there was practical stagnation a year or more ago. A commission has been appointed to make further studies of metalliferous prospects as well as to investigate the resources of potash salts withdrawn by the Government from location in the provinces of Barcelona and Lérida. The Minister of Fomento has also appointed a technical commission to make a detailed study of the oil prospects in the vicinity of Cádiz, where a number of wells have already been drilled. In addition, this commission will study the coal resources of Asturias and the underground waters of Almería. The strike of the

coal-miners in Asturias, which was declared on August 13, tied up the output of this vital necessary for a time, but an adjustment has been made by which it is hoped that further difficulty will be avoided. The demands of the workmen were not excessive, and were in no sense intended to cripple the industry.

Under the leadership of Viscount de Eza an association of the coal producers of Asturias is being effected, which is intended not only to further the development of coal mining in this large and important basin, but to regulate the industry in such manner as to meet the exigencies of trade after the War. It is understood that guarantees of some sort will be sought from the Government, before any considerable developments are undertaken, it being pointed out that while the difficulty of obtaining coal from abroad has resulted in the extraordinary development of the native resources, so that the indications are that the Spanish coal mines will meet the domestic demand in 1918, they will be laboring under a difficulty in competition with foreign sources of supply after the War, unless some means of protection is assured. Viscount de Eza affirms that it would be unfair to burden manufacturing industries in Spain with a higher cost by imposing a duty upon imported coal for the sake of protecting a new and struggling industry. It is thought that recourse will be had to a direct bounty upon the domestic product sufficient to protect the coal miners against cut-throat competition from abroad. Under these circumstances it is believed that a large development of the coking industry will be undertaken, and the Government has already proposed to erect an experimental plant for coal-washing in order to assist in the development of these deposits. In conjunction with the coal-washing, the Government engineers propose the distillation of the slate washed from the coal in order that the valuable combustible materials may be conserved.

A report was recently issued through the Geologic Institute written by Señor Mallada regarding the coal deposits at Guadalcanal in Sevilla. It is a very brief description of the geology of the district, and it also touches upon the relations of this deposit to those of Córdoba and Badajóz. It is believed that the coal deposit, which lies parallel to that of Bémez, that is north-west and south-east, passing approximately about 3½ miles north-east of Guadalcanal, is connected with the coalfields of Fuente del Arco. The geologists of the Institute are working upon the problem in order to construct a geological cross-section of these coalfields for which data at the present time are not available. Analyses of the coal from the mine of San Epifania, near the Arroyo of Cortijo Viejo de Castelló are as follows:

	Samples		
	1	2	3
	%	%	%
Volatile hydro-carbon .....	36.60	36.80	38.00
Fixed carbon .....	49.07	48.54	50.00
Ash .....	14.33	14.66	12.00
Coke (by test) .....	63.40	63.20	63.00

A large part of this coal lies within 15 metres of the surface, and much of it is not deeper than three to five metres. The field lies nearly horizontal, and it is thought it will be possible to operate by first stripping the over-burden. The Government has undertaken to fix the rates of transportation on coal from the coalfields of the country.

In the Spanish zone in Morocco several concerns are operating mines of hematite, lead, and zinc. The Cia. Español de Minas del Rif exported from the Port of Mellila 6000 tons of hematite, and the Cia. del Norte Africana has shipped 87,957 tons of lead and zinc ore. The zinc occurs in the form of calamine, and the lead as galena. Development of mines in Morocco is hindered by inability to obtain bottoms in which to ship the output.

# THE MINING SUMMARY

## ALASKA

(Special Correspondence.)—W. Martin, of the Alaska Free Gold, is in town with the bi-weekly clean-up of the mill. He reports the mill, which is a Lane Chilean, as producing \$100 per day.—Theodore Pilger, from Butte, has been making examinations in the Willow Creek district.—Joseph Morris, representing Spokane people, who has been prospecting on a group of copper claims on Iron creek, 40 miles from Talkeetna, is in town on his way south. He brought a large number of samples that have been assayed in the local office with gratifying results. He says the district is one of great possibilities, numerous well-mineralized outcrops exist that have never had a pick or a shot put into them.

Anchorage, October 4.

(Special Correspondence.)—Lynch brothers, diamond-drill contractors, recently completed a three-year contract at the Perseverance mine and have sent the machine and crew to Kennecott, where two machines are now working. During the term of the contract at Perseverance over 75,000 ft. of diamond-drill holes have been run. The Lynch brothers now have machines working at Jualin, Ellamar, Latouche, El Capitan, and two at Kennecott.

The trestle over the cave at the Treadwell has been started; most of the piles are in place.

Treadwell, October 7.

Orders have been received from Washington to close the Federal Mine Inspection Office at Juneau at once, for an indefinite period. John A. Huff, who has been in charge of the office for the past three months, has been instructed to report to Washington at the earliest possible moment. Sumner S. Smith, the Federal Mine Inspector, is at present superintending the opening of the Government coal mine on Eska creek for the Alaska Engineering Commission. The records of the office will be sent to him there.

## ARIZONA

### GRAHAM COUNTY

(Special Correspondence.)—Since last December considerable development work has been done on the Silver Cable claim, part of the holdings of the Grand Reed Mining Co., which has been leased to T. Parks of Tucson. This property has a small well-defined vein of molybdate of lead. A road to this property has been completed and grading for a 100-ton mill commenced.

Safford, October 11.

### GREENLEE COUNTY

(Special Correspondence.)—The smelter of the Arizona Copper Co. is the only active plant in the Clifton-Morenci district. It is operating on custom ores. The mines are being closed for an indefinite period, irrespective of the decision of the Federal inquiry, which is expected to take place in a week or so.

Clifton, October 12.

The Mexican and Spanish miners who had voted to return to work at the mines at Clifton have voted to rescind their action until after President Wilson's labor investigating committee holds its hearing. Meanwhile it appears the mines will

remain idle. Sheriff Slaughter, who is holding 70 Mexicans of the 400 who marched on Clifton from Morenci, contradicting the statement recently given out by Gutierrez, the Mexican consul, in which the latter said the Mexicans were going peaceably to Clifton to go to work. The sheriff said the advance party of Mexicans told him and his deputies they were going to run the 'scabs' and Americans out of Clifton.

### MARICOPA COUNTY

(Special Correspondence.)—A syndicate, formed last May to re-open the Buckhorn and Boulder mines in the Goldfield district, is now forming a company to further develop the property. In cleaning out and re-timbering the old shaft and workings high-grade carbonate ore was found, and also a lode of chalcopryite beneath the oxidized zone. Cross-cutting has proved the ore to be over 15 ft. wide. While sinking the shaft at the Abe Lincoln property, a body of chalcopryite ore has been opened at the 96-ft. level which appears to be the main orebody. It is planned to sink to a depth of 500 ft. A compressor and other machinery have just arrived at the mine and orders have been placed for an electric pump.

Phoenix, October 11.

"While the labor commission is in Arizona it will endeavor first to settle all existing labor troubles in the mining districts by mediation," stated William B. Wilson, secretary of labor and head of the special commission appointed by President Wilson to investigate and act in labor troubles of all kinds throughout the West, which began its labors at Phoenix, October 5. Charles H. Moyer, of Denver, president of the Mine, Mill, and Smelter Workers union, arrived on the same train that brought the commission. Members of the commission are William B. Wilson; J. L. Spangler, of Pennsylvania; Verner C. Reed, of Colorado; John H. Walker, of Illinois; and E. P. Marsh, of Washington. Felix Frankfurter is secretary, Max Lowenthal, assistant secretary, and R. B. Horner, clerk.

### MOHAVE COUNTY

(Special Correspondence.)—The new hoisting plant at the Chloride Queen has been completed and sinking of the 100-ft. shaft another 200 ft. will commence immediately. Development work at the United Northern will be resumed as soon as the new machinery, now on the property, is in place. Bids are being received for sinking the shaft of the Oatman-Golconda from the 25 to the 425-ft. level. This property consists of six claims lying between the Pioneer and Leland, both of which have been producers in the past.

Oatman, October 15.

### PIMA COUNTY

(Special Correspondence.)—The controlling interest in the Mile Wide Copper Co. has purchased the Wakefield-Belmont group of 19 claims in the San Xavier district and development work is to commence immediately. Increased production in the San Xavier district has prompted the continuation of the Twin Buttes railroad to the Bush, Vulcan, and Mineral Hill properties. These properties are now hauling to Tucson.

Tucson, October 13.

### PINAL COUNTY

(Special Correspondence.)—The Curry Mining Co. in the

Superior district announces that actual development will start in a couple of weeks. A road has been completed and buildings are being erected. It is announced by the Queen Creek Copper Co. that, in the inclined shaft which is being sunk to the 500-ft. level, good gold-copper ore has been opened from 300 to 325 ft., the present bottom of the shaft. The Magna Chief Copper Co. is making preparations for diamond-drilling to commence November 1. A body of silver-lead ore, exceeding any yet developed, has been opened up on the Cincinnati claim of the Ray silver-lead mine. Machinery which arrived recently is being erected. There are about 85 men working at the mine and 285 burros packing the ore.

Florence, October 9.

#### YAVAPAI COUNTY

(Special Correspondence.)—When the new addition now being made at the United Verde crushing plant and smelter is completed, which will be early next summer, it is expected that the United Verde will double its present output of 6,000,000 lb. of copper per month.

Jerome, October 16.

#### YUMA COUNTY

(Special Correspondence.)—Mr. Ormsby, superintendent of the Wenden copper mine, has recently reported a strike of high-grade ore in a cross-cut from a shaft. The Black Giant has added another shift of men. The Rainier Development Co. has re-organized as the Ranier Mines Co., having taken over claims of the Harqua Hala Ridge Mining Co. Lessees on the Bullard property have a force of fifteen men working. They are using an Ingersoll compressor and two jack-hammers. The Wenden King has closed down temporarily until repairs can be made on its 50-hp. Fairbanks-Morse gasoline hoist.

Wenden, October 18.

### CALIFORNIA

#### COLUSA COUNTY

The erection of the new machinery to replace that destroyed by fire at the Ceresse mine is nearly completed.

#### DEL NORTE COUNTY

The Cold Spring chrome property, owned by G. W. Gravin of Grants Pass, has been in operation for several months. Although extensive prospecting has been done the mine has produced only a few hundred tons of ore.—Chrome mining is still increasing in the Low Divide and French Hill districts, many tons being shipped daily. William Hawkins has located a number of chrome deposits in the Low Divide district and is shipping ore to San Francisco.

#### ELDORADO COUNTY

John C. Evanis is mining one ton of 40% chrome ore daily from a deposit about three miles north-west of Clarksville. He is doing the mining alone and gets \$16 per ton for ore at the mine, from where auto-trucks haul it to Folsom.

#### INYO COUNTY

Important changes are in progress in the mills at Tungsten. The Standard company, with L. E. Porter, superintendent and general manager, will have a new Marcy mill in operation within the next two or three weeks. All but one part of the machinery is now on the ground. In the meantime the old plant is running steadily while construction of the new mill is going on, there being room to place the new machinery without interfering with the old for more than three or four days in the final stages. The new mill will bring the capacity up to 200 tons per day.

Base Metals Mining Co., at Big Pine, is shipping 300 tons of silver-lead ore per month to the U. S. Smelter Co. at Salt Lake.

#### NEVADA COUNTY

The Columbia Consolidated has completed the construction of a 20-stamp mill at the Ocean Star mine, near Washington.

#### SHASTA COUNTY

(Special Correspondence.)—A carload of ore per day has been shipped for the last month from the Star shaft of the Bully Hill mine to the smelter at Kennett. The proceeds help to continue the development work, on which \$75,000 has been spent already by the Arnstein interests. The company is contemplating putting in a flotation plant at Copper City.

Kennett, October 15.

(Special Correspondence.)—Six hundred thousand brick used in constructing furnaces and roasters for the Balaklala Copper Co. at Coram have been sold to a Redding builder. The Balaklala has a long-term contract for treatment of its ore at the Mammoth smelter, at Kennett, three miles away.—J. A. Wilson, with the consent of the Superior Court, has bonded the land of the Drew minors near Gas Point for dredging purposes. Prospecting with a Keystone drill will begin shortly.—The Mammoth, Mountain, and Balaklala are running, though with crews smaller than before the strike. The Mammoth has resumed work at its outside mines—the Stowell, Spread Eagle, Friday-Lowden, and Sutro. The Mountain Copper Co. has resumed work at Hornet, Iron Mountain, and United States mines, the last being near the Balaklala.

Redding, October 17.

A second manganese furnace has been completed at Heroult, increasing the capacity from 200 to 400 tons of ferro-manganese per month. Ore is being shipped from a number of points, and several new deposits are being worked.

#### SIERRA COUNTY

(Special Correspondence.)—W. A. Loftus, W. A. Sage, and other Los Angeles capitalists have purchased the huge concrete restraining dam recently erected on Slate creek, and acquired 90,000,000 ft. of virgin gravel channels in the vicinity of St. Louis, Scales, Howland Flat, Poverty Point, Port Wine, Whiskey Diggings, and other old hydraulic-mining camps. A large adit will be driven to Poverty hill through which tailing from the several properties will be run to the restraining dam. The dam is 50 ft. high and is so situated that its height can be easily increased to 150 ft. The company is incorporated under the title of the Loftus Blue Lead Gold Mining Co. Steel flumes will be used in place of the usual ground-sluiques.—A new deposit of gravel has been uncovered in the Herkimer mine at Howland Flat, showing considerable coarse gold and occasional nuggets. Supplies have been shipped in and operations will be pushed steadily throughout the winter season. G. De Brettville is manager.—High-grade ore containing arsenical pyrite has been intersected 220 ft. from the adit-portal of the High Commission group. Water is hampering mining; work probably will be suspended until the spring. The claims are owned by John Reid and Sheriff Johnson.—Mining in the north end of Sierra county is active, but shortage of skilled miners is keeping down production. Around Sierra City a number of mines are producing steadily, notably the Sierra Butte and Monarch Consolidated. At the latter driving of the new main working adit is proceeding steadily. Prospecting is active above Downieville, and in the Alleghany-Forest district the situation is satisfactory.

Downieville, October 21.

#### TRINITY COUNTY

(Special Correspondence.)—The development of the Silver King, four miles west of Redding, is attracting the attention of mining men. L. E. Parker, of Butte, Montana, after a thorough examination, organized the Silver King Mining Co., of Salt Lake, at San Francisco, with Robert Sloan as president. Over 1200 ft. of development has been done. The silicious

copper ore is mined from an altered andesite dike 70 ft. wide and more than a mile long. The ore is found on both the hanging and foot-wall and runs 33 oz. silver to a unit of copper. Two cars are being shipped every ten days to the smelter at Kennett. L. E. Parker is general manager and M. M. Johnson, consulting engineer.—The Barron Gold mine, nine miles east of Ashland, Oregon, has been purchased by H. J. Sallee of Redding from the Byron L. White estate. The vein is 16 ft. wide, and contains gold, silver, and antimony in paying quantities. Development consists of a 200-ft. shaft, 750 ft. of levels, and a 5-ft. winze. Sixty men are to be employed with John Kemple as superintendent. The ore will be shipped to Kennett smelters.

The 10-stamp mill, at the Strode mine, near Carrville, is being run continuously. The owners have spent \$40,000 on development and plant in the last 14 months. H. L. Stewart, one of the owners, is superintendent.

Redding, October 15.

#### TUOLUMNE COUNTY

(Special Correspondence.)—The Italian Camp group of mines, situated above Phoenix lake, has been acquired by an Eastern company. G. L. Caulfield is superintendent; a few men are getting things in shape preparatory to more extensive work. It is stated that the company will re-open the old Belleview, an adjoining property that has been idle 25 years.—Twenty men are employed at Black Oak, near Soulsbyville. The mill has been operated intermittently on ore from the 1400 and 1900-ft. levels, with satisfactory results.—A new body of rich ore has been uncovered on the 810-ft. level of the Confidence mine. A 100-ton roller mill is being erected.—A shaft is being sunk at the Erin Go Braugh, situated north of the Golden Rule, near Stent. The mine is held under bond and lease by W. E. Booker and Ed McGinn. The shaft, which is 100 ft. deep, exposes some good ore. A pumping plant has just been put in.—The erection of a mill on the Ruby mine, in the Groveland district, is contemplated by A. Steinmetz, owner of the property. A considerable quantity of \$30 ore has been taken out in development, and the vein is expected to average \$8 per ton. The main adit is in 190 feet. Sonora, October 17.

### COLORADO

#### BOULDER COUNTY

(Special Correspondence.)—John L. Bell has made a big strike on his properties near Sunset. Mr. Bell is one of the oldest miners and prospectors in Boulder county, with several big producing mines to his credit.—J. D. Hume, of Post City, Texas, is at Boulder attending a meeting of the stockholders of the Tungsten Mountain Mining Co., of which he is a heavy stockholder.—The old camp of Ward is having a real boom. The Big 5, White Raven, Modoc, Utica, Grand View, and scores of others are busy. The price of silver has given a new impetus to Ward, gold and silver properties vying with each other for supremacy.—The old Independence mine above Eldora will be re-opened; work has already been started, with Henry Martin in charge. The property belongs to the Rockwell Bros., of Denver.—Several auto loads of men interested in the Huron mine were down this week looking at the property. Active operations will be continued all winter, and steady shipments made. Guy M. Woodring has been in Denver completing arrangements for extensive improvements.—C. E. Kahler, of Columbus, Ohio, president of the Consolidated Leasing Co., returned home for a few days. The machinery for the mill has arrived, and it will be completed as soon as possible. W. F. Harper is manager.—Gunter, Dirakis, and Ludlow will work their property near Hesse this winter.—A. R. Scofield of the Dixie has opened up a fine body of high-grade ore.—John A. Wilson has purchased his partner's interest in several claims at Woodlawn.

Eldora, October 9.

(Special Correspondence.)—The Moore Mining, Milling & Developing Co. is doing a big amount of development work on the Livingston dike at Sugar Loaf. The company is composed of Boulder men and has been operating in this district for the past three years. The Nil-Desperandum group of mines in the Sunshine district has purchased the Inter-Ocean property. It has also enlarged and increased its milling plant and is working on a large scale. It is heavily financed. This property was one of the old producers in the early days and is among the famous old properties of this telluride camp. S. M. Brandt is manager of the property.—The Tungsten Mountain Mines Co. was greatly pleased with the report of Mr. Clark, the manager, given at the annual meeting of the stockholders. Increased development work will be conducted.—Around Lakewood centres the big producing mines of the tungsten belt: The Clyde mine, operated by the Wolf-Tongue company, and the Gale. The Vasco is doing a big business. The Primos Co. is operating crews on Conger, Lonetree, Corkscrew, Beddig, 18, and 4. The milling capacity has been doubled during the past year. Other improvements are also being made. Some of the most productive private leases are the Rake-Off, Lily, Old Donnelly, Spider-Leg, Bob Cat, and No. 19 on the Coon patent.—The fifth annual meeting of the Colorado Metal Mining Association will be held at Denver next January. The value of the metal output in Colorado for 1916 was \$49,200,675.—The big silver excitement at Caribou still continues, and another strike is reported. Miners and prospectors are rushing in and all available ground is being taken up. Several sales have been reported.

Eldora, October 15.

#### LAKE COUNTY

(Special Correspondence.)—The Derry Ranch Gold Dredging Co. paid its eighth dividend on October 1, and the total dividends up to that date amounted to 100%. It has produced \$278,301 up to that time, and the ground averages 28c. per yard. This is the second year of operation. The property has a life of five more years, in which it is expected that the present yield will be maintained.

Leadville, October 20.

### IDAHO

#### SHOSHONE COUNTY

The second stack at the big smelter of the Bunker Hill & Sullivan M. & C. Co., at Kellogg, has been blown-in; the company has been operating steadily for several months with one furnace; a third one, completing the plant as now planned, will be blown-in about November 1, giving the smelter a capacity of 600 tons of ore or concentrate per day.—The Hecla Mining Co., operating at Burke, has declared its regular October dividend of \$150,000. This disbursement will be on a basis of 15c. per share on the 1,000,000 shares issued. It will increase the total payments this year to \$1,500,000 and the grand total to \$6,895,000. The company reported a net profit of \$1,681,059 last year. It ranked third in the district, being exceeded only by the Hercules and the Interstate-Callahan in the order named.—The first unit of a mono-rail road, which will transport lead-silver concentrate from the mill of the Highland-Surprise mine to the end of the spur which will be built this winter up Pine creek, in the Coeur d'Alene, has just been completed. The concentrate is now being hauled by wagon, at a cost of approximately \$4 per ton for the nine miles from the mine to the O.-W. R. & N. The mono-rail will cut the cost to 25c. per ton. The road consists of a light steel rail spiked to the top of an 8 by 10-in. timber, supported by wooden uprights and braces. Below the top timber are wooden guide rails. The locomotive has for its motive power a converted Ford engine attached to the driving wheel by chain and sprocket. On either side, low enough to throw the centre of gravity of the car below the metal rail, are bins, each of which

will contain a ton and a half of concentrate.—A dividend of 3½c. per share has been declared by the Tamarack & Custer, one of the big mines of the Coeur d'Alene, making the disbursement \$53,287. Stock of record October 15 will participate. This is the third dividend the company has paid. In May and again in April of last year it paid 2c. per share, making disbursements totaling \$71,050.

## MONTANA

### LEWIS AND CLARK COUNTY

(Special Correspondence.)—The old Honey Comb, Mt. Pleasant, Blue Bird, and Hickey claims are being developed.—The Barnes-King Development Co., owner of the Shannon, paid a dividend of 10c. per share on 400,000 shares. This is the first dividend paid under the present management. The company is working the Shannon and the Piegan-Gloster mines at Marysville and the North Moccasin group, together with the original Barnes-King.—The Economy Mining Co., which is operating 15 miles east of Helena, has unwatered the 300-ft. shaft and is mining a high-grade gold-copper ore. Five mines are shipping ore from Grass Valley district and a like number from Scratch Gravel hills.

A. B. Woolvin has been at Helena consulting with his engineer, L. S. Ropes, who has charge of a large group of gold-mining claims in the Marysville district. The claims are known as the Marysville Gold Syndicate group, but were formerly called the Marysville Gold Mining Co.; they were secured at the instance of M. L. Hewitt, who interested Maurice Eisenberg, of New York. After spending considerable money Mr. Eisenberg transferred the entire holdings to A. B. Woolvin and associates of Duluth, Minnesota. Considerable development has been done and the showing is fair.—The Amalgamated Mines Co., a new corporation, has acquired the Free Coinage group in Lump gulch and has located 25 additional claims. The aim is to unwater the Free Coinage which is about 350 ft. deep. No work has been done on the property for 25 years. The company also owns ground in Grass Valley, California, and in Nevada.—The Economy Mining Co., operating in Mitchel gulch, 12 miles east of Helena, has unwatered its 300-ft. shaft by electric power, lately put in, and has resumed mining.—The Mt. Washington mine near Wickes continues to send out one 50-ton car of ore per day. The ore is taken from the vein at the face of the adit, which shows 14 ft. of galena ore.—Grass Valley and Scratch Gravel hills are sending a considerable tonnage to the smelter every week.

Helena, October 15.

## NEVADA

### HUMBOLDT COUNTY

The completion of the 350-ton mill of the Rochester Combined Mines Co. has been delayed by the difficulty in obtaining some essential machinery; it will probably not be started before January or February. The company is centering its activities on the Happy Jack shaft, Shepard adit, and Kromer winze, work having been discontinued on the Link adit, and many of the outlying claims.—The Packard mill is crushing 100 tons per day. The new Walter open-cut, as well as the Margrave cut, is producing a quantity of good ore, mined entirely by 'glory-holing.' Mill-ore is being produced from the 160 and 120-ft. levels, which are being rapidly developed. Forty-nine men are employed.—The sulphide orebody, cut by the Rochester Mines Co. several months ago, continue to produce excellent ore, with an increased ratio of gold to silver. The mill at Lower Rochester is treating 200 tons per day, and the monthly clean-up averages \$65,000. The Packard-Rochester district has produced over \$2,225,000 in the past four years. Aside from the \$68,000 paid in dividends by the Packard, and payments made to original claim-holders in the district, stockholders have received no returns.

An announcement of much importance to the district was recently made by the Nenzel Crown Point Co. The United States Smelting, Refining & Mining Co. has contracted to take 100 tons of ore per day from the Nenzel Crown Point, Lincoln Hill, and Buck-and-Charley, the greater proportion to be furnished by the Crown Point. The silicious ore is desirable as a flux and it is understood that a very low treatment-charge will be made. The ore will be shipped to the Kennett smelter. This will mean the rehabilitation of the Nevada Short Line railroad running from Oreana, on the Southern Pacific, to Rochester. The Nenzel Crown Point has blocked out a large quantity of low-grade silver ore. The Buck-and-Charley and Lincoln Hill are small properties at Lower Rochester.—Some good ore was recently found on the Hoffman and Beecham claims adjoining the old Relief mine, five miles south-east of Packard. The Relief was one of a series of phenomenally rich but shallow silver-gold deposits opened along the Humboldt Range in the 'sixties and 'seventies of the last century.

Lower Rochester, October 11.

### NYE COUNTY

At the White Caps the past week has been devoted almost entirely to breaking ore for the mill, the average production of 100 tons per day being maintained with ease. Practically the only development work has been on the fifth level, the east orebody having been exposed during the week for an additional 32 ft. The total length of the ore so far is 65 ft., although each day's work is adding an average of six feet to this length. The level on the ore has been kept along the foot-wall of the vein, so that the dimensions between the walls cannot be determined. The orebody yields \$30 per ton; next to the foot-wall assays run as high as \$65. Car samples taken on October 10 for the entire day's hoisting gave an average of \$38 per ton. The vein is as strong and well defined in the present face on the fifth level as anywhere in the mine.—The week's work at the Amalgamated is as follows: From the 600-ft. level the north cross-cut on the fissure has been advanced 16 ft., No. 11 north cross-cut east 14 ft., and the south cross-cut on fissure 34 ft. The total for the week is 64 ft. The recent development work in the mine has demonstrated conclusively that the two orebodies which had been mined in the Earl shaft from the 350-ft. level to the surface have come together at the present 600-ft. level. The average assay-value of the orebody, eliminating all samples which assayed higher than \$17, is \$14 per ton. There is still one more orebody known as the Swanson ore-shoot which remains to be proved from the present bottom level, and should this be of the same size and richness as proved in the Earl upper workings, it will yield over 8000 tons of \$20 ore. The working shaft on the Earl is to be straightened, enlarged to double-compartment with manways, and timbered with eight by eight. From the present bottom of the shaft, 350 ft., it is to be sunk, and a raise started from the 600-ft. level of the Amalgamated workings, to make connection with the shaft bottom. This work is to be carried forward at once and the requisite underground surveys are being made. Owing to the fact that a complete hoisting-plant is in place at the Earl shaft in addition to the plant worked by the company several hundred feet farther west on Litigation hill, there will be no delay in the carrying on of this work, and development will be continued as well from the 600-ft. level in exploring new ground, to pick up the downward extension of some important orebodies which have yielded well. It is the intention of the management to remove the mill from its present position and re-build it on Litigation hill, convenient to the Earl working shaft. When this is done several important changes in construction will be made to reduce the operating cost and increase the tonnage. In all probability the stamps will be replaced by ball-mills, as the Litigation Hill ore is soft and friable and ideal for such treatment.

The week's work at the Manhattan Consolidated has been devoted to driving the east drift from the fourth level and the south cross-cut from the third level. The east drift is 90 ft. from the shaft. The formation in the face of the drift has changed into much tighter ground, being now a black hard lime-shale. The point where the east orebody should be found is still about 160 ft. from the face.

The Manhattan Red Top will shortly have the heavy flow of water, that has caused so much delay in shaft-sinking, within bounds. The management announces that a large Cameron sinking-pump has been shipped from San Francisco and should reach the mine before the end of the week. The quartz lease recently granted the Red Top by the Union Amalgamated Mining Co. is an important concession to the latter, as it gives access to some promising ground which on the surface shows several rich stringers of ore that can be easily reached from the Red Top's working shaft.

The Manhattan Morning Glory is prospecting in an inclined shaft, about 150 ft. east of the old Pine Nut shaft. This work is 90 ft. from the surface; some rich quartz stringers are being followed.

## NEW MEXICO

Fire completely destroyed the plant of the Empire Smelting & Refining Co., situated a mile and a half east of Deming, on October 4, entailing a loss of \$20,000, about half of which is covered by insurance. The fire started when a pipe carrying gasoline broke while the engineer, Horace Deuil, was heating a burner under the oil-burning engine. Flames quickly spread to all parts of the structure and could not be stopped by the fire-department from Deming, which had to pump water from a reservoir near the smelter. Mr. Deuil was slightly burned. L. C. Baker is the manager and W. H. Seamon the superintendent of the company, which is financed by Eastern men. The plant smelted lead-silver-gold ores and was doing a thriving business on ores from the districts surrounding Deming. The plant will be re-built at once.

## OKLAHOMA

### OTTAWA COUNTY

Protection for a mining plant in the shape of a barbed-wire fence 8 ft. high, charged with electricity, is something new for this district, but is what is planned by the W. E. Merrill Mining Co. property north of Quapaw. The plant is nearing completion and is one of the most up-to-date in the district. Besides the thoroughly modern mill, the company has erected a 40-room hotel for the accommodation of its workers, and a club-house for its officials, with a concrete floored garage that will hold ten automobiles.

The equipment at the Merrill plant comprises three 7-cell rougher-jigs, with cells 36 by 42; one cleaner-jig, with seven cells of the same size, and a 5-cell sand jig. Power is furnished by Fairbanks-Morse oil engines, one of 150-hp. being used to drive the compressor, two of 100-hp. to drive the mill and hoist, and one 75-hp. for the sludge department. There are 18 sludge tables, a Dorr thickener and classifier, and a set of 42-in. high-speed rolls for re-grinding. There is also a 90-in. classifying screen, which is an unusual feature for a sludge-room in this district. The mill is virtually completed and it is expected that the plant will be ready for operation by the first of November.

## OREGON

### JACKSON COUNTY

(Special Correspondence.)—There is evidence of steady activity and increasing interest in the mining and prospecting in Jackson county. The government price on copper has served to quell the excitement about that metal, but the established price is quite sufficient to keep the present plants active.

Clark & Webb, of Medford, have leased the Gold Ridge gold

and silver mine on Kanes creek, three miles south of Gold Hill, owned by T. C. Norris, of Medford. They have a crew operating a 3-stamp mill and developing a 20-ft. vein that averages \$100 per ton in gold and silver.—M. G. Womack, of Medford, and M. A. Clark, of Ashland, representing Trinity county, California, people, have taken a lease on the old Red Oak gold mine, three miles south-west of Gold Hill, on Galls creek. This property produced \$40,000 from the 60-ft. level 25 years ago, but since then it has been idle owing to litigation. Recently it fell into the hands of John Ralls and Claude Lawrence, local miners, who will re-open the 300-ft. level. The vein is three feet wide. W. M. Cowley, president of the Cowley Investment Co., and Howard H. Startzman, both of Seattle, have been inspecting the Copper King copper mine on Grave creek, 20 miles south-west of Gold Hill. They announce that their re-organization plans have been adopted. The mine is owned by the United Copper Co. of Seattle; it is fully equipped and there is a large orebody said to run 36% copper. A new wagon-road from the mine to Rogue River, eight miles west of Gold Hill, is being made.—Earl M. Young, of Rogue River, has sold his manganese property near Wimer, 12 miles west of Gold Hill, to Seattle steel people, who will develop the mine. The ore occurs in small veins running through serpentine.

Gold Hill, Oregon, October 9.

## UTAH

### UTAH COUNTY

The directors of the Iron Blossom Mining Co. met at Provo October 10 and declared the usual dividend of 5c. per share or \$50,000, payable October 25 to stock of record October 15. This brings the company's total up to \$3,110,000 and makes a total for the year of \$250,000, a highly gratifying result. The mine was reported in excellent condition.—The directors of the Dragon Consolidated posted the usual dividend of 1c. per share or \$18,750 with similar dates, making this company's total \$75,000, all of which has been paid this year. This property also was reported in good shape.—Earnings of both mines were said to have been affected by the car-shortage, although development work had resulted in piling up a considerable quantity of ore which would be shipped just as soon as cars were available.

The Rico Wellington has been unable to ship on account of scarcity of labor and car-shortage, but this has not affected the condition of the mine, which was said to be in good condition.—The directors of the Miller Hill Mining Co. have levied an assessment of 2c. per share on the company's capital stock, delinquent November 12, sale day November 30. This gives the company a total of \$14,000 for further development work on the property in American Fork canyon.

The Mineral Flat Mining Co. has also levied an assessment of 1c. per share, delinquent November 12, sale day November 30. This will raise the sum of \$10,000, which will be expended in development.

An assessment of 3c. per share has been levied on the capital stock of the Tintic Central Mining Co. The assessment becomes delinquent November 15, sale day December 8. The assessment is to cover costs of running the drift through the Iron Blossom into the Tintic Central on the 1700-ft. level of the Iron Blossom and on the 1500-ft. level of the Tintic Central. The drift has been extended into Tintic Central ground 140 ft., and is 500 ft. lower than any previous work on the property.

## BOLIVIA

The deputies in session at La Paz have for some time been discussing a new project of law, which would place a tax upon copper, whether produced for treatment as raw ore or in the form of concentrate. Congress is also considering new treaties with Germany.

**BRAZIL**

The State Government of Minas Geraes is expected within a short time to impose a duty of 8% on all manganese exported. On account of this, energetic efforts have been made to export as large quantity as possible before such a tax might apply. In the month of August manganese ore transported by the Central railroad exceeded 50,000 tons, which is a quantity without precedent in the Republic.—Edwin Morgan, U. S. Ambassador to Brazil, has announced that the United States will send to Brazil at once 120 engineers, specialists in different technical branches, as an industrial commission to study the resources of the country, but with special reference to the possibilities of developing the timber resources of Brazil. The commission will also study the question of transportation, which, at the present time, is a great impediment to developing the mineral resources of several States.

For some time past capitalists from Rio de Janeiro have been producing coal in the form of briquettes made at the mines of Barra Punta, situated in the State of Paraná. These are being used with success by railroad companies and manufacturers.

**CANADA****BRITISH COLUMBIA**

The Trail smelter has issued a notice stating that in future no ores containing over 4% of zinc will be accepted. Practically all the silver and lead ores in British Columbia carry a larger proportion than this; the smelter used to allow shipment of ore carrying 8% without imposing a penalty. The effect of the new order was marked on the Vancouver Stock Exchange by a slump in practically every British Columbia mining property listed. In anticipation of the continued need of the Imperial Munitions Board, 15,000 tons of lead ore in addition to about 2000 tons of lead matte had accumulated at Trail. The board has now informed the management of the smelter that, owing to a reduction in shrapnel making, it is unable to take more than 1000 tons of lead per month until January 1. After that date the requirements of the board are uncertain. In order to meet the situation a reduction in the shipments became necessary. Shipment of lead ore from the Sullivan mine has been stopped. By adopting the policy of accepting only that ore containing 4% zinc or less the smelter will be able to put more ore into the furnace and in that way clean up the large accumulation on hand.—Negotiations are pending for the amalgamation of the interests of the Little Bertha and Pathfinder properties on the North Fork.—The Aberdeen mine on Ten-Mile creek has been re-opened. T. J. Corwin, the manager, has just returned from the coast, where he made financial arrangements for developing the mine.

**MEXICO**

(Special Correspondence.)—Notices have been posted throughout the camp at Cananea that all difficulties between the Cananea Copper Co. and the Mexican government have been adjusted and that the mine and smelter will resume operation shortly.

Cananea, October 15.

**PERU**

William C. Gastes has obtained a concession from the Government for the exploration and ultimate denouncement of gold placers near the headwaters of the Rio Inambari and its principal tributaries. The concession grants Mr. Gastes three kilometres on each side of the main axis of flow of the river Inambari and two and a half on each side of the axis of flow of the main tributaries. The islands and high banks of the rivers are included in the concession. It is understood that the concession restricts the rights of the concessionaire to operations conducted upon an important scale, which involves considerable engineering work.

**PERSONAL**

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

F. W. BRADLEY is at Kellogg, Idaho.

R. M. ATWATER was at Joplin last week.

JOHN A. DRESSER, of Montreal, is at the St. Francis hotel.

VICTOR RAKOWSKY, of Joplin, was in New York this week.

C. A. ROMADKA passed through San Francisco on his way to Eureka, Nevada.

GEORGE W. BRYANT, formerly at Guanajuato, Mexico, is now at Joplin, Missouri.

CLYDE T. GRISWOLD is spending a vacation at home after a summer in Wyoming.

HENRY HAY, formerly in South Africa and Chile, is now at Santa Ana, California.

ERNEST GAYFORD, of the General Engineering Co., Salt Lake City, has been to Alabama.

LLOYD C. WHITE, mill-superintendent for the Mountain Copper Co., is in San Francisco this week.

HARVEY S. MUDD is at Washington, serving as assistant secretary to the War Minerals Committee.

S. B. WEED has become engineer to the Keweenaw company, succeeding G. M. NORTH, now in the Navy.

HOYT S. GALE is inspecting nitrate deposits in southern California for the U. S. Geological Survey.

H. W. EDMONDSON has been appointed Captain in the Engineer Reserves and is at Osage City, Kansas.

J. H. DEVEREUX has become a member of the firm of WILKENS & DEVEREUX, with offices at 120 Broadway, New York.

JAMES J. NORTON has been appointed ore-dressing engineer with the U. S. Bureau of Mines at the University of Minnesota.

T. A. RICKARD has returned from St. Louis, where he attended the meeting of the American Institute of Mining Engineers.

W. A. ARGALL has joined the 148th Regular, Battery C., U. S. Field Artillery, and is at Camp Green, Charlotte, North Carolina.

R. B. EARLING and FERDINAND MEINECKE, JR., have joined the 166th Depot Brigade, and are at Camp Lewis, American Lake, Washington.

WARREN D. SMITH passed through San Francisco on his way from the Philippine Islands to the University of Oregon, at Eugene, Oregon.

JAMES F. KEMP has joined DORSEY HAGER and M. BATES, making the firm of Hager, Bates & Kemp, petroleum geologists, at Tulsa, Oklahoma.

JOHN C. GREENWAY, general manager for the Calumet & Arizona Mining Co., has joined the Army and expects to leave for France shortly.

LAWRENCE ADDICKS and A. F. KUEHN sailed from Vancouver on October 25 on their way to the Bawdwin mines of the Burma Corporation.

H. C. MILLER is superintendent of the Round Valley Tungsten Co., at Bishop, California, succeeding COOPER SHAPLEY, who is now general manager.

A. W. FAHRENWALD has resigned the position of professor of metallurgy with the New Mexico School of Mines to accept an appointment with the A. S. & R. Co. at El Paso, Texas.

PEARSON JOHN CLAUDET died recently in London. He was the metallurgical partner in the well-known firm of F. Claudet, Ltd., assayer to the Bank of England. He survived his elder brother Arthur by only a few years, and although he had been in ill health for some time, his death was sudden and unexpected.

# THE METAL MARKET

## METAL PRICES

San Francisco, October 23

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	16.50
Antimony (wholesale), cents per pound.....	14.75
Electrolytic copper, cents per pound.....	23.50
Pig-lead, cents per pound.....	6.75—7.75
Platinum, soft and hard metal, respectively, per ounce.....	\$105—111

Secondary metal is a term used by the U. S. Geological Survey for metal obtained from scrap, sweeping, skimming, dross, and refuse, as opposed to primary metal that is obtained from ore. The total quantity of secondary copper recovered in 1916, on the assumption that the brass re-melted had an average copper content of 70%, was 350,000 tons, of which 52,212 tons (22,425 tons more than in 1915) was recovered by plants refining primary metals and the remainder by plants treating only secondary materials. The copper produced by smelters of the latter class includes 74,100 tons of pig-copper, 14,000 tons of copper in alloys other than brass, and 210,000 tons of copper in re-melted brass. These figures indicate an increase for 1916 of about 20,000 tons of pig-copper, 113,750 tons of copper in brass, and a decrease of about 2000 tons in alloys other than brass. At least 175,000 tons was recovered from clean scrap made in the course of manufacture of copper and brass ware, so that less than 175,000 tons was obtained from ashes, cinders, and scrap, or from material that had actually been used and discarded. From the reports received it is quite evident that there was an increase in the quantity of old scrap brass and copper smelted and that there was a much larger proportionate increase in the quantity of clean new scrap re-melted. The increase in the quantity of scrap brass used amounted to 162,000 tons, and of this increase at least 100,000 tons was clean new punchings, filings, and clippings. The decrease shown in the quantity of secondary copper in alloys other than brass was undoubtedly due to including alloys containing tin (which properly

should be termed bronze) under the classification brass. The value of the copper, both as metal and in alloys, is computed at the average yearly price of 24.6c., the average sales price of all marketable grades of new metal.

## LEAD

Lead is quoted in cents per pound, New York delivery.

Date	Average week ending
Oct. 17.....	7.00

## MOLYBDENUM AND ANTIMONY

Reports are that \$2.25 has been paid for high-grade molybdenite, while for 90% concentrate \$2.20 is the prevailing quotation. The antimony ore market is unchanged.

The production of secondary antimony, of which all but 80 tons was recovered in alloys, increased from 3102 short tons in 1915 to 4480 tons in 1916. The value assigned is arbitrary and is based on the average yearly price for ordinary brands of antimony published by the 'American Metal Market.' The regular smelters reported the recovery of 528 tons of antimony contained in antimonial lead scrap, an increase of 52 tons. The principal materials refined or re-melted which contained antimony as an alloy were hard lead dross, babbitt, solder, pewter, and type metal. The imports in 1916 of antimony as metal in ore or as oxide or salts amounted to 11,928 tons, and the recovery from secondary sources was equal to 33% of the imports. The production of antimony from antimonial lead and antimonial lead ores of domestic origin in 1916 was about 4500 tons, or about the same quantity as that recovered from secondary sources.

## CHROME

Quotations in this market are hard to obtain but it is stated on good authority that chrome-ore is hard to buy and that not less than \$1 per unit, f.o.b. New York, for 45 to 50% ore would have to be paid to obtain California grades.

# Eastern Metal Market

New York, October 17.

All the metals are inactive. There has been no buying except in tin and this has not been large. Price-fixing has been reported as about to be extended to lead and zinc.

Copper is at a standstill and nominal.

Tin is steady with some business done in futures.

Lead is unsettled and weaker with prices considerably reduced and they may go further.

Zinc is stagnant and fairly firm at mostly nominal prices.

Antimony is dull and unchanged.

Aluminum is inactive and lower.

Outside of Government orders business has been light in the steel market. Sales of steel have been made at both the fixed prices and higher, the latter, in the case of 1000 tons of billets at \$50, representing largely the closing of options, made before the price announcements. Signs point to the consummation of sufficiently numerous sales before long to establish a public market at the agreed figures.

## COPPER

The general uncertainty which has prevailed for some time is still with us. What appeared to be a definite or early clearing of the atmosphere last week has not materialized. Various reports are circulating but definite information is not available. Joint separate meetings of committees representing the producers and consumers are being held daily with the object of unraveling the tangle regarding distribution. It is probably known what the Government and Allies' requirements are for the last quarter, but how much is to be left for general consumption is not made public if indeed it is known. It is probably true that the producers are now permitted to deliver metal on old contracts, but no copper can be sold at the new Government price of 23.50c., which we continue to quote as nominal. The intricate problem will probably be solved soon, but until then business is practically at a standstill in order to conserve the Government's interests and that of the Allies. Small lots to needy users continue to go at about 28c. per lb. The London market is quiet and unchanged at £125 for spot electrolytic and £121 for futures.

## TIN

The week has been generally quiet, with no features of special interest. On the holiday, Friday, October 12, there was no market, and previous to that, on October 10 and 11, practically no business was done, except the sale of 25 tons of February shipment from the Straits at 57c. On Saturday, October 13, good inquiry for November, December, and January shipment from the East appeared and two lots of 25 tons each for January and February shipment from the Straits went at 57.37½c. On Monday, October 15, further good inquiry appeared. Two lots of 50 tons each of January and February shipment from the East went at 57.62½c. In all, about 300 tons of futures were sold as well as some nearby metal. Yesterday the market was quiet, with buyers showing but little interest, though there were fair sales quietly made of January-February shipment. In the entire period since our last letter there has been practically no business in spot-tin. This has come to be regarded as in a specialty-class, for shipping permits are hard to obtain unless the buyer's name is stipulated. Since last week the price has not fluctuated outside of 60.62½ to 61c., New York, the latter having been the quotation yesterday. Arrivals to October 15, inclusive, have been 1540 tons with 4520 reported afloat. The London market is strong, having advanced £2 since a week ago to £247 10s. per ton yesterday.

## LEAD

There have been two important developments since the one mentioned in our last letter to the effect that the Government's October requirements would be furnished below the agreed price of 8c. per lb. if the quotation for the month of the 'Engineering & Mining Journal' showed an average below 8c. The new developments include the report of price-fixing by the Government of pig-lead at 6c. or under, which is unconfirmed, and the unexpected and sudden announcement of a reduction of 1c. per lb. by the American Smelting & Refining Co., bringing its quotation to 7c., New York. While a reduction was looked for, its proportions exceeded expectations. Four months ago lead was selling at 12c. and buying was good. This is the fifth decrease in price since August 29, bringing the price to the lowest level it has reached in a year. It is not surprising that the market is now unsettled, with buyers uninterested and expecting a further drop, influenced by Government price-fixing. The reason for the decline has been few offerings of round lots for any delivery this year at concessions below the 8c. price, but no buying resulted. We quote the market at 7c., New York, but offerings under this are already rumored.

## ZINC

Into a market that has been on the verge of nervous prostration, and that has been lifeless and stagnant for the greater part of several months, is now injected price-fixing by the Government. It is reported, but unconfirmed so far, that "price-fixing of lead and zinc by the War Industries Board is imminent as a result of investigations into both the lead and zinc industries by the Federal Trade Commission. Complete figures on the cost of production of the two commodities have been sent to President Wilson and the Navy Department. After consideration has been given to the data an announcement from the White House probably will be made." This has caused a dampening rather than an inspiring effect. The market continues dull with little interest or demand. It is, however, fairly firm with prime Western for early delivery quoted at 8c., St. Louis, or 8.25c., New York, and ¾ to ¼c. per lb. now asked for latter positions. Sales, however, are not of consequence. The apparent firmness is due largely to the fact that quotations are very near to the cost of production. Another factor by no means making for an upward trend in the market is the mid-year report of the U. S. Geological Survey on spelter. This shows that up to June 30 inclusive, smelting capacity was still being enlarged despite the unsatisfactory market conditions. The total number of retorts on June 30 was 233,050, an increase in the half year of 13,632, with about 15,000 additional building or planned.

## ANTIMONY

Chinese and Japanese grades are quoted at 15c. per lb., New York, duty paid, but demand is poor and the market is dull.

## ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is lower, being quoted at 38 to 40c. per lb., New York, but there is no demand and prices are nominal.

## ORES

Tungsten: There is no change in this market. Scheelite continues to command a higher price than other ores, \$26 per unit on 60% concentrate being the quotation which has been realized in recent moderate sales. From \$23 to \$25 is quoted on other ores. Inquiry is reported good. Ferro-tungsten is unchanged at \$2.30 to \$2.50 per lb. of contained tungsten.

# INDUSTRIAL PROGRESS

## FOLSOM STATE PRISON INSTALLATION

The State of California has recently established a new record for a low-head hydro-electric development, in connection with the installation made at one of the State Prisons, about two miles east of Folsom, on the south side of the American river, which is a tributary to the Sacramento, having its source in the Sierra Nevada range. This unusual harnessing of water-power is a triumph of present-day installation on the site of an original development, which, historically speaking, was the pioneer in power-transmission, dating back to 1866. A project was inaugurated at that time to develop a manufacturing centre at Folsom, utilizing the water-power of the river in its fall between the town and the prison-site. The original development, it is understood, was made under about 7-ft. head, and consisted of six vertical-shaft turbines of 75 hp. each, the power being transmitted through bevel gears to a horizontal jack-shaft, from which, by means of rope-drives, a two-cylinder single-stage air-compressor and a horizontal plunger-pump, a refrigerating plant, and a machine-shop were driven.

The head and the flow present considerable variation and during several months of the year it is necessary to provide for power from outside. The variation in head is from 8½ ft. under normal conditions, to 12 ft. during exceedingly dry seasons, when the tail-water level is much lower. In other words, the variation in head on these turbines may amount almost to a 50% increase over the normal head, and it was necessary to select turbine-equipment for the new installation which would operate under these unusual conditions. It requires approximately 400 hp. to meet the demands of the prison, and the old granite flumes, extending underneath the powerhouse, in each of which was originally placed one of the 75-hp. turbines, were found to have a flow-capacity capable of handling about 300 cu. ft. of water per second within the limits of good engineering practice for maximum permissible velocity. It was, therefore, decided to place two turbines, one in each of two of these old flumes, and to make the turbines of sufficient capacity so that the two would develop the required 400 hp. This necessarily required a runner designed for high specific speed, having great water-capacity, in order to reduce the size of the generator as much as possible.

Each of the two vertical-shaft wicket-gate turbines recently installed has a runner of 51 in. mean diameter, operating at 100 r.p.m., and having a maximum capacity of 220 hp. under 8 ft. 6 in. head; 280 hp. under 10-ft. head; 365 hp. under a 12-ft. head, maintaining a constant speed throughout this variation of head. The design of the turbine is such that, while the power-output increases more than 50% when the head is increased to 12 ft., the efficiency of the turbine under the 12-ft. head is very high, which is an important factor in the plan of

operation, because, when the head is low, there is ample water, and a slightly lower efficiency is not objectionable, but, with the higher heads which occur at low-water stage the quantity of water available is limited and the highest efficiency is therefore necessary in order to reduce the amount of power, which must be purchased from outside. The turbines are of the wicket-gate type, and consist of steel-bucket runners with hubs and bands of cast-iron, these runners being securely keyed to a vertical shaft and held in place by means of a split-ring

CROSS-SECTION OF TURBINE SETTING

GENERATOR-FLOOR, FOLSOM POWER-INSTALLATION

recessed in the lower end of the shaft. There is no extension or shaft below the runner-hub, but the extension above the runner is of such length as to connect to the generator-shaft, a forged flange being provided for this purpose. This runner is mounted in the wheel-case, consisting of heavily constructed top and bottom plates, between which the wicket-gates are hinged on steel gate-pins extending through the gates and through the top and bottom plates in such manner as to be securely bolted and to be easily accessible for adjustment or replacement of any gates, which replacement can be made without interfering with the other parts of the turbine. The

top plate is provided with a substantial steady bearing, in which lignum vitae blocks are placed, and which are adjustable to take up wear. The bottom plate is flanged so as to carry the shifting ring or gate-ring, which is connected to each gate by means of a link. The gate-links, as well as the gates, are bronze-bushed, and the connection to the gate-ring is made by means of an eccentric bolt which provides a slight adjustment to each individual gate. This gate-ring is operated by means of two push-and-pull rods which connect to a rocker-arm on the vertical gate-shaft, and to which connection is made on the generator-floor for governor and hand operation.

The accompanying cross-sectional illustration shows the vertical shaft, wicket-gate turbine complete with its vertical shaft, direct-connected generator, installed in the original masonry flume, in connection with which a curved concrete draft-tube has been carefully designed and constructed. This view also shows the extreme low tail-water level; also the normal tail-water level, and the normal head-water level.

In changing over this power plant, all the mechanical drives for the compressor and refrigerating plant were abandoned and all machinery was driven by induction-motors. The main power-house floor on which the generators are placed consists of an 8-in. slab of reinforced concrete at an elevation of 9 ft. above the main floor of the building, this being necessary in order to afford sufficient head room on this main or sub-floor, and also to provide for a jack-shaft between the two turbine-shafts. The object of the jack-shaft is to furnish power by means of belt-drives to the exciter, also the oil-pump which is a part of the governing mechanism, and also to drive the governor-speed balls. The counter-shaft is driven by means of rawhide bevel gears meshed in cast-iron bevel gears with split hubs clamped to the turbine-shaft. The two turbines are controlled by one governor of 10,000 ft.-lb. capacity, and it is so arranged that both turbines may be controlled by this one governor, or one turbine by the governor and the other by hand, or the reverse connection, or both may be regulated by hand, as the case may require. This makes an ingenious device which has been worked out carefully, and has operated successfully. The governor is placed on the generator-floor between the two generators with two operating cylinders of horizontal type set close to the floor so that the piston-rod of the operating cylinder extends through both heads. The connection is made to the gate-shaft of the turbine by means of a lever-arm carried on the ball thrust-bearing which supports the weight of the rotating gate-shaft. The hand-wheel mechanism is mounted in a substantial housing provided with an eccentric which is moved by a hand-lever. This arrangement works with extreme ease; in fact the turbine-gates are so designed that one man can easily handle them without difficulty, while the governor moves them with an oil-pressure as low as 60 lb. The generators are of special design because of the low speed and the unusually low capacity for machines of this speed. Each machine is a 72-pole alternator of 200 kva. nominal rating, wound to deliver 2300 v., 3-phase current. These machines were tested at a run-away speed of 200 r.p.m., or 100% over-speed, which is a condition that might occur with the turbines operating at a run-away speed under the maximum head of 12 ft. The rotor has a cast-iron spider, to the rim of which the 72 pole-pieces are bolted, this rim having considerably more weight than is necessary for the required strength in order to provide additional fly-wheel capacity for governing purposes, the fly-wheel effect in each rotor being 80,000 ft. sq. lb. The generator-shaft extends below the floor-level and is provided with a forged flange-connection to the forged flange of the turbine-shaft. The thrust-bearing on top of the generator carries a total load of 25,000 lb., which includes the weight of the revolving element of the generator, plus the weight of the turbine runner and shaft, and the hydraulic thrust of the runner.

There is a four-panel black slate switchboard fitted with all

the necessary indicating and recording instruments for the two generators, three out-going feeder-circuits, and an incoming 2300 v., 3-phase, supplied from the power-house of the Pacific Gas & Electric Co. There are also three motor-starter panels, one of which controls the 75-hp. induction-motor for driving the pumps that supply the prison water-system, another controls the 100-hp. motor which drives a compressor, and the third for controlling a 40-hp. motor used as a reserve-drive for the exciter. The air-compressor is mounted on an extension of the generator-floor, as is shown in the cross-sectional view. An illustration of the generator-floor is also shown, in which are the two generators, the belt-driven exciter, the governor, and the switch-board. The hydraulic turbines, with all jack-shaft mechanism, were furnished by the S. Morgan Smith Co. of York, Pennsylvania; the generators and exciters were furnished by the Allis-Chalmers Mfg. Co.; the governing mechanism by the Woodward Governor Co.; the compressor by the Ingersoll-Rand Co.; and the switch-board by the General Electric Co. The entire plant was designed and installed under the supervision of Rudolph W. Van Norden, engineer, under the authority of State Department of Engineering, and the installation was handled by the labor of convicts at the State Prison.

## FLEXOID SYSTEM OF VENTILATION

Mine-ventilation takes a large amount of time in connecting and fitting rigid pipes, and the ordinary galvanized pipe employed easily becomes buckled and opens up at the joints, thus reducing the efficiency of the ventilating system. The Bemis Bro. Bag Co. of St. Louis, Missouri, has developed a system of flexible pipes to overcome these difficulties, which is said to reduce the operating cost from 15 to 25%, and to effect a great saving in time. This is accomplished with what is called 'Flexoid', a material for pipes made by saturating strong canvas with a patented preserving compound. This protects the fibre against dry-rot, acid water, and the action of the weather. After saturation with this compound it is then coated on one side with a heavier compound that fills up the pores and gives a smooth surface, making the canvas absolutely air-tight. The finished product is tough and flexible, and withstands the severest conditions of mine work. Flexoid pipes are coupled by two contracting-rings with flanges sewed in each end of the tube. In order to couple them each end is taken and pressed into the sides of the rings, placed at right angles to the other, and slipped through. The ring is then in the mouth of the tube. The rings are placed parallel and the tube on each section allows the flanges to catch the end and hold fast. For use in shafts a suspension-collar is fitted around the coupling and four guy-wires are passed through holes in the sides and attached to the walls of the shaft. One collar to every 100 ft. in depth of the shaft is sufficient even for a 12-in. pipe. The Flexoid is made in short lengths as well as longer ones, so that the pipe may be connected close to the work. Before blasting the last section is removed, and this can be done within three minutes. N. B. Braly, general manager for the North Butte Mining Co., writes regarding this ventilating system as follows:

"Flexoid canvas tubing has now been in practical operation in the mines of this company, both in shafts and tunnels, for about a year, and I have no hesitancy in stating that the results have been most complete and satisfactory. In my opinion it is the perfect ventilating medium for mining operations, and is valuable alike to the prospector, contractor, and mine operator. In tunnel driving we have found Flexoid so portable that 1000 ft. can easily be placed by a single man in half a day, and the back of the tunnel does not need to be altered, as the line will readily conform itself to any angle or curve. In stoping underground pipes can be carried to any

possible location where tubing is required, thus filling a long-felt want that could not be met with metal tubing. For supplying fresh air to the men, cooling off places of high temperature, and removing smoke from workings after blasting, we have found it invaluable. In the last case the workings are cleared rapidly, allowing resumption of work in a very short time, thus resulting in a great saving of costs."

Flexoid is now used by many of the progressive mine managers of the United States and South Africa. It is universally regarded as a great improvement upon the rigid pipe formerly employed.

## HAULAGE COSTS REDUCED BY DUPLEX TRUCK

Ward C. Hill, superintendent of public works, Lansing, Michigan, asserts that Duplex trucks which are being used on

the Duplex company will be paid for the first year by the saving in haulage costs which results. Motor-trucks that are dependable, that are on the job in all kinds of weather, and with sufficient power to haul capacity-loads up grades and over soft newly made roads, are money savers and money makers for any city. Our road-building work is being carried on much more efficiently with motor-trucks, and we are accomplishing twice as much as we did under former conditions with teams and wagons."

## LINK-BELT ROPE TRAMWAY SYSTEM

The Link-Belt Co. has issued a pamphlet describing the Watson type of tramway and power-system as circular No. 343. This rope-system, designed to embody all of the good features of the man-trolley, and, in addition, to eliminate the heavy carriage, makes possible high speeds and easier and more

DUPLEX TRUCK ON STREET WORK, LANSING, MICHIGAN

street work in that city have reduced the cost of hauling gravel nearly one-half.

"It cost \$1.75 per yard to haul gravel from the pit to the streets in the city when we used teams and wagons," said Mr. Hill. "The cost with Duplex trucks is 90c. per yd. By replacing our teams and wagons with Duplex trucks, we have not only reduced our haulage cost nearly one-half, but we are improving our streets in much less time than was possible with teams and wagons. We expect to reduce these costs still further in the future by the use of trailers. Our fuel-cost will be increased very little by attaching a trailer to each Duplex, while we will be enabled to haul about three additional yards of gravel each trip. I am firmly convinced of the economy of motor-trucks over teams and wagons for municipal work and expect that the motor trucks which we have purchased from

certain control with a reduced consumption of power and a lessened cost of installation. It is claimed that by this it is possible to duplicate the usual operation of a man-trolley carrying a nine-ton bucket by using a six-ton bucket. The cables are relatively short and can be removed and replaced without disturbing the main operating cable, and in addition, can be changed from the standard clam-shell to a clean-up bucket without disturbing the main operating cable. A slack-motor is carried to the closing drum. This is a series-wound motor which operates only in one direction, with the power running idle in the hoisting direction, and is for the purpose of taking up the slack-cable when the bucket is being opened, and to assist in opening the bucket quickly. This motor varies from 5 to 15 hp., depending upon the length of the bridge and its use obviates the necessity for any mechanical slack-carriers.

The motor operates automatically from electrical contact in the main hoist-controller, and requires no attention from the operator.

## COPPER IN HARDENING STEEL

In a paper presented before the British Iron and Steel Institute, L. Grenet, of Firminy, discussed the penetration of the hardening effect in chromium and copper-steel. As the result of his tests, Mr. Grenet declared that 1% of copper sufficed to enable steel containing 1.5% chromium to sustain the hardening effect in point of depth. According to Mr. Grenet, the action of copper is more limited than that of nickel-chromium-copper steels containing less than 3% nickel, soften on annealing at high temperatures, and consequently do not harden on quenching when the rate of cooling is slow. The simultaneous employment of copper, nickel, and chromium permits the preparation of semi-hard steels which can be hardened by air-cooling in large pieces, and yet softened by the ordinary annealing methods used for carbon-steels. The limits of chemical composition within which such steels should fall are wide enough to render their manufacture easy. The chief influence of copper is to increase the depth of the penetrative influence of the quenching, and consequently the effectiveness of heat-treatment in the interior of the pieces.

## INDUSTRIAL NOTES

The BLAW-KNOX Co. announces that it has decided to close its Boston office, since many of its salesmen and engineers have been drafted into the national service. The business formerly handled through the Boston office will be cared for by the New York office at 165 Broadway.

Paper mills have special conditions to meet in preserving metal surfaces. In the industrial process, hot moist vapors are evolved which set up deterioration of metal surfaces of the digesters, pipe-lines, pumps, and other surfaces with which they come in contact. ORONITE ENAMEL PAINT has been successfully used by many paper mills on the Pacific Coast to prevent this deterioration.

MEESE & GOTTFRIED Co., the manufacturers of conveying, elevating, screening, and mechanical power-transmitting machinery, whose headquarters are in San Francisco, have opened an office in Salt Lake City, in order to more adequately take care of their rapidly increasing business in that territory. G. E. Phillips, one of the firm's engineers, in charge of the new office, reports bright prospects, having already picked up several large orders.

ZELNICKER'S BULLETIN No. 220 shows a large amount of light railway equipment, including locomotives and miscellaneous rolling-stock, available for immediate delivery. There are also a number of steam-shovels in the list. Other attractive items are belted, electrically driven, and steam air-compressors, boilers, crushers, stationary engines, machine-shop tools, pumps, and steel piling. Zelnicker's address is at 325 Locust street, St. Louis, Missouri.

'Mineral Foot-Notes,' issued by the FOOTE MINERAL Co. of Philadelphia, for the month of October, contains an interesting account of monazite and its occurrence in different parts of the United States, together with a discussion of the uses of monazite, and the current market prices. It also gives an account of 'cooperite', a new high-speed alloy of zirconium and nickel, which has been introduced as a competitor of 'stellite'. Cooperite tools are said to cut for 49 minutes before needing to be re-ground, and at a speed of 85 ft. per minute, on a cut of  $\frac{1}{8}$ -in., with a feed  $\frac{1}{32}$ -in., without lubrication. There is also an

account of 'zirkite' ware for laboratory use, such as combustion tubes, connectors, filtering crucibles, pyrometer protection tubes, chimneys, and muffles. This ware attracted a great deal of attention at the recent Exposition of Chemical Industries in New York. Prices of the less common metals and their compounds are also given.

The TEMISKAMING & NORTHERN ONTARIO RAILWAY has just issued an extremely handsome pamphlet on the mineral wealth along its line, which was published in connection with the recent itinerary of the Governor-General and other dignitaries of the Dominion. Beautiful illuminated plates showing gold ore from the Croesus mine, silver ore from Cobalt, and other cuts showing the occurrence of veins in the Porcupine and Cobalt districts, are included.

The BORDEN Co. of Warren, Ohio, announces a novel arrangement for operating a Beaver die-stock. C. Risager, a plumber of Aberdeen, South Dakota, received a contract for a large plumbing job in the country, which required haste. Not wishing to move a heavy standard power-machine, he secured a shaft having a universal joint at each end. One end of this shaft he fitted to the rear axle of his Ford truck, and the other end to the driving pinion of a No. 41 Beaver 'easy working die-stock,' threading pipe, from  $2\frac{1}{2}$  to 4 in. This arrangement did the work with a great saving of time and expense.

The WESTINGHOUSE ELECTRIC & MANUFACTURING Co. announces another increase in wages for shop employees, aggregating nearly \$2,000,000 per year. All employees observing shop-hours, with the exception of munition workers, will receive an additional bonus of 10% if on a salary or time-rate basis, and 7% if they are on a piece, premium, or task-basis. The Westinghouse company has one of the most highly skilled organizations in the country, consisting of 20,000 shop employees. Since the outbreak of the War the increase in wage has amounted to 60% over the former average compensation.

The OLIVER CONTINUOUS FILTER Co. has just issued Bulletin No. 11 on the 'Use, Construction, and Operation of Oliver Filters', which will be of value to prospective users of filtration apparatus. It gives illustrations of these machines as applied, with oscillating agitator, in soda manufacture, others adapted to sugar filtration, and others operating on mill slime and on flotation concentrate. The importance of the thin cake which is built up on the Oliver filter is accentuated, the advantage being that such a cake is firm, homogeneous, and permeable, admitting of even washing with no excessive use of wash-water that would cause losses due to channeling and cracking. In the Oliver filter the thin cake is built up rapidly, and is under observation the moment it emerges, as also during the period of washing and discharging. By varying the speed of rotation of the drum and the feed of the pulp, the agitation, and the vacuum in use, an adjustment can be obtained, ensuring a perfect cake, which will then continue automatically without further attention. Cracking of the cake is obviated in the Oliver filter by rigid backing under the filtering surface, this surface being maintained smooth by means of wire-winding. The maximum vacuum required may be given during submergence, but, as the cake emerges, it may be advisable to decrease the vacuum so as to prevent too rapid drying and shrinking of the cake. As soon as the solution disappears beneath the surface of the cake, the wash-water may be applied, effecting a thorough wash without mixing the solutions. The automatic valve can be adjusted so that one or more washes may be given and the filtrates kept separate. If the solution contains salts, which tend to crystallize or to clog the filter-medium, steam, or additional air, may be admitted through another port, which is controllable through the automatic valve. This is accomplished without stopping the filter.

MINERALS SEPARATION .....	Page 632
Canadian protest against a flotation-monopoly; accusations that the Minerals Separation is pro-German not justified; personnel of the company is strongly pro-Ally; Canadian Government in a position to control such efforts at monopoly; proposed to regulate the royalty; suggestion that the Dominion might purchase the patent rights for the benefit of the Canadian mining industry. <i>M. &amp; S. P., November 3, 1917.</i>	

MAKING A CAREER .....	Page 633
W. J. Loring an example of the self-made engineer; reference to James Parks, Charles D. Lane, and H. C. Hoover; training for obtaining the economic result in mining; handicap of a lack of technical training; some advantages of the practical school in character-building. <i>M. &amp; S. P., November 3, 1917.</i>	

### DISCUSSION

MILL-TESTS V. HAND-SAMPLING .....	Page 635
By R. E. RAYMOND AND STANLY A. EASTON..... Merits of the Webber system of sampling; would have revealed actual value of ore at Alaska Gastineau mines; respective defects of moil-sampling and mill-tests; variation of sampling-error between one mill-test and its neighbor the governing factor.—The engineer should visualize conditions for actual stoping as a guide in sampling; correct sampling is mining in miniature. <i>M. &amp; S. P., November 3, 1917.</i>	

WATER AND MINES IN PARADISE .....	Page 636
By J. D. HUBBARD .....	
Troubles of miners in the Paradise irrigation district; cases of Lucky John mine and the action in Mineral Slide Mining Co. v. Pacific Gas & Electric Co. <i>M. &amp; S. P., November 3, 1917.</i>	

METHODS OF MINING .....	Page 637
By GEORGE J. YOUNG..... Historical development of the caving system of mining; its origin found in coal-mining methods; top-slicing also an adaptation of coal-mining methods; block-caving developed from the long-wall system. <i>M. &amp; S. P., November 3, 1917.</i>	

MILL-TESTS V. HAND-SAMPLING .....	Page 638
By F. F. SHARPLESS..... The Webber system a safe rule when the engineer's judgment is sound in applying the correction; example of selective large-sampling checks; greatest	

difficulty found in small, high-grade, erratic veins. *M. & S. P., November 3, 1917.*

### ARTICLES

W. J. LORING. A CALIFORNIAN ENGINEER .....	Page 639
AN INTERVIEW. BY T. A. RICKARD..... Early career; advancement in practical mining; experiences at the Utica mine; called to Western Australia; impressions of H. C. Hoover; work in Burma, and later in Ontario; observations on shareholders' meetings; the Hollinger mine; re-opening old mines on the Mother Lode in California. <i>M. &amp; S. Transporting Union Drill over 40-Mile Trail

These field Photographs show what can be done with a

## UNION CHURN DRILL

Upper picture shows the drill being transported over forty-mile Alaskan trail.

Center picture—drill set up and drilling 6 $\frac{3}{4}$ -in. diam. hole to a depth of 60 ft. at rate of 2 to 2 $\frac{1}{2}$  ft. per hour using  $\frac{8}{10}$  gals. gasoline per hour.

Base picture shows drill being moved to next hole by drill-crew. Weight on wheels 2150 lbs.

Insert shows a block of granite, fifteen inches thick, with a 4 $\frac{3}{4}$ -in. diameter hole drilled through in a demonstration. Time, one hour and fifteen minutes.

Engineers and Dredge Builders

*Agents for Bucyrus Placer Dredges on the Pacific Coast, in British Columbia and Alaska*

**T**YPOGRAPHICAL errors on our advertising pages are not debitable to the editorial department, but we venture to draw attention to such an error on the first page of our issue of September 29, where the horsepower required by the Marcy mill is given as 255, whereas the copy said 225.

**C**OPPER dividends declared during the first nine months of this year make a total of \$139,000,000, as compared with \$108,000,000 in the same period of last year. The biggest contributor is the Utah Copper, which paid \$17,869,390 in the first three quarters of 1917. The Anaconda paid \$15,153,125, and the Kennecott \$13,054,616. No other company paid over ten millions, but the Phelps-Dodge group distributed \$9,900,000, the Inspiration \$7,387,294, and the Calumet & Hecla group \$7,500,000.

**E**XEMPTION from assessment work on mining claims under the recent Act of Congress applies equally to lode and to placer claims. The notice of desire to take advantage of the Act for exemption does not need to be in the form of an affidavit, but may consist merely of a letter to the official recorder authorized by the State law to record notices of location of mining claims in any district or county, giving in the letter such a description as will unquestionably identify the claim. If the other facts can be accompanied by a citation of the book and page of record, all question as to the identity of the property will be obviated.

**O**N October 25 Dr. Ira N. Hollis, chairman of the National Engineering Council, president of the American Society of Mechanical Engineers, and president of the Worcester Polytechnic Institute, was entertained at dinner in San Francisco, and on that occasion delivered an address on 'The moral influence of engineering and efficiency.' We hope to publish the text of this address in our next issue; meanwhile we venture to remark, as on the occasion of Dr. Wilbur's recent address before the Commonwealth Club, that the serious public utterances of our leaders of thought receive no attention from the daily press, whereas the vaporings of cheap notorities are given ample space. More than that, the engineer, who is the king-pin in our

organization to wage successful war, is not recognized as being at least as important as the talkative lawyer or the nondescript politician, two types that embarrass our national efficiency at this crisis.

**S**PELTER exports from Atlantic ports during the first seven months of this year amounted to 255,005,289 pounds, as against 177,993,047 pounds in the same period last year and 142,051,969 pounds the year before. At the end of this seven-month period, however, exportation decreased considerably, that for July being the least for the year, at 19,769,286 pounds, as against 29,097,748 pounds in June and 61,912,499 pounds in May. England continues to be the chief importer, taking 98,201,360 pounds in seven months. Canada took 17,242,373 pounds. The contracts made with the allied governments are helping our spelter industry, but while the market is regulated by the abnormal demands of war, it is bound to be subject to vicissitudes, and we expect therefore that the Government will fix a price with such limitations of trading as will prevent speculation.

**A**NNOUNCEMENT is made that the American Zinc, Lead & Smelting Company has adjusted the penalties for infringement and damages claimed by Minerals Separation, agreeing to pay the latter \$250,000 during the next 12 months, this payment being divided into \$50,000 cash and two sums of \$100,000 in six and twelve months respectively. The smelting company becomes a licensee of the patent-exploiting company. This agreement was made against the advice of Mr. D. C. Jackling, who has resigned from the directorate of the American Zinc, Lead & Smelting Company. The sum to be paid by the latter is just half of the figure mentioned by the Minerals Separation people a month ago. We sympathize with Mr. Jackling in his protest, which we believe to have been made in the interest not only of the company of which he was a director, but also of the mining industry as a whole. As regards the Butte & Superior Mining Company, it is satisfactory to note that the order signed on September 17, whereby the company was required to file a bond for \$2,500,000 and to deposit monthly all the proceeds of its operations, less actual expenditure, has been modified, so that now the company is enjoined from disposing of its

assets until the final termination of the suit and payment of judgment. The company is given permission to apply to the local court for leave to incur extraordinary expenses for betterments. Thus the filing of a bond for \$2,500,000 is obviated, the Minerals Separation people stating that they consented to the change because they wished to avoid any procedure "that would restrict the output of metals in war-time." The order of the Court provides further that the Butte & Superior company shall file monthly reports of its operations and shall monthly deposit in Court the actual receipts, less actual expenses, "or a bond in the amount thereof that they will be forthcoming for application upon any profits and damages finally awarded to the plaintiffs." Preparations for the appeal are being made, and the defendant has good reason to expect that Judge Bourquin's decision will be reversed.

OUR compliments to Os Estados Unidos do Brazil! "The land of bloodless revolutions" has gone to war! She may not send a great army to Europe, though she could train and equip more men than Italy has lost in her terrible reverse in the Julian Alps. The problem would be to transport them and to maintain them when there without straining an already overburdened trans-Atlantic food-service. She will, of course, dispatch a body of troops so that the Germans may see another banner adding to the blend of national colors like a menacing aurora over her frontiers, and they will be good fighters, too—those Brazilian standard-bearers. The man that is slow to take up arms proverbially proves a worthy foe, and Brazil has a record of some relentless and effective fighting against Rosas in the Banda Oriental and against Lopez on the banks of the Paraguay. What Brazil's entry into the War chiefly means as an aid to those now struggling to save the Anglo-Latin civilization is a loosening of international relationships, so that the important contributions of Brazil to the stock of needed supplies may be forwarded without the limitations imposed by an observance of neutrality. Moreover, Brazil might render a notable service by mustering a great industrial army to plant more cotton and sugar in Ceara and Maranhão, and to raise more grain in Parana, and to improve transportation facilities for the metals needed from Minas Gerais.

## Minerals Separation

It is apparent from recent issues of the 'Canadian Mining Journal,' the 'Northern Miner,' the Toronto 'World,' and other papers across the border, that the company claiming a monopoly of rights to the flotation process has been under the fire of journalistic shrapnel. The 'Canadian Mining Journal' has maintained a dignified and correct attitude throughout this campaign, with the result that it has been attacked by its less responsible contemporaries. A charge has been made that Minerals Separation, more particularly its American

subsidiary, is under German control. We stated the facts succinctly in these columns in our issue of October 6. Nothing has happened since to call for a revision of the statement then made. The connection, as agents at New York, of Beer, Sondheimer & Co., a German firm placed temporarily on the black list of the British government, is the chief evidence on which Minerals Separation is charged with being a German corporation anxious to hinder the production of war-metals in the United States and Canada. Since December 1916 the American business of Minerals Separation has been in the hands of the Minerals Separation North American Corporation, the directors of which are Messrs. John Ballot, S. Gregory, and Frank Altschul, the last holding a commission in the American army. We infer nothing from the naturalized citizenship of this or that director, nor do we think that the efforts to separate the identity of the British parent company from the American subsidiary is of any importance, but we do feel absolutely confident that Mr. J. H. Curle, well known to readers of our paper, and a man of unimpeachable loyalty, as also of unquestionable honor, could be no party to any attempt to interfere with metal production in the interest of the Enemy. Amid the various charges of the Canadian press and the explanations published by Messrs. Ballot and Williams, we place our reliance squarely on the good faith of Mr. Curle, who is a director of Minerals Separation and a close friend of Mr. Ballot. Mr. Curle's association with the enterprise gives us confidence in Mr. Ballot personally and in Minerals Separation as a corporation. We believe that the papers at Cobalt and Toronto are barking up the wrong tree. We agree with them that Minerals Separation, with its attempted patent-monopoly, is a pestilential nuisance to the mining industry, but we see no good in beclouding the issue with false charges. The 'Canadian Mining Journal' brushes aside the mis-statements of the daily press and reviews the position in an eminently sane fashion. We appreciate our contemporary's reference to ourselves. Our attitude is now prejudiced, for good reasons, but we did not come to the conclusion that Minerals Separation's claims to a monopoly were unjustified by the facts of discovery without first making an honest and thorough inquiry. The patent-mongering company has tried to bluff the metallurgical profession in America by imposing an invalid agreement on technicians employed by its licensees, it has tried to exact extortionate royalties, and it has endeavored persistently to stifle the publication of information concerning the technology of the process. The decisions of the American courts have been, in the main, favorable to Minerals Separation, but the end is not yet. Meanwhile the patent laws of Canada afford better protection to the public than our own and we expect that any attempt to impose an unreasonable royalty can be defeated. It is to be hoped that the Mines Department of the Dominion will give serious attention to the question, not only in the furthering of metal production, but in the vital

interest of the mining industry. Owing to the closer control exercised by the Canadian government over patent royalties and over mining regulations, especially in this time of war, it ought to be practicable to bring the Minerals Separation people, whether in New York or London, into a sensible frame of mind and to make some arrangement with them, whereby the mining industry of Canada may be relieved of an incubus. We hope that the Canadian Mining Institute and the 'Canadian Mining Journal' will unite in pressing the subject upon the attention of the Canadian government with a view to granting relief to the mining industry of the Dominion and preventing a further development of a tyrannical, extortionate, and stifling control upon the output of base metals.

Since writing the above we have received a telegram from the 'Northern Miner' stating that Mr. Frank Cochran, who was Minister of Lands, Forests, and Mines in Ontario before entering the cabinet of the Dominion government, stated at Cobalt on October 24 before a 'Win the War' convention: "It will be my business to see Sir Robert Borden [the Premier] on the question, with a view to bringing them [the M. S. people] to their senses, and, for the benefit of the mining community, I shall try to get him to cancel their contracts." He informed the meeting that, if, after a thorough investigation, it were found that the control was not vested in German alien enemies, it would be the duty of the Government to see that the royalty imposed was so reasonable that it would in no way embarrass the industry or in any way retard the development and production of Canadian metals. In this connection he suggested that the Government would appreciate the advice of operators in Canada as to what, in their estimation, would be considered a fair and reasonable royalty. This is the summary as telegraphed by our courteous contemporary at Cobalt. We are glad to see that attention is being given by the Canadian government to the question, and we hope that the mining profession in Canada will bestir itself to co-operate with the proper departmental authorities. As to a fair royalty, five cents per ton regardless of quantity would yield a handsome income for the patentees without being burdensome to the operators of mines. The Anaconda and Inspiration companies, with others in that group, are paying 4 cents per ton on an aggregate output in excess of 30,000 tons daily. We do not believe in a royalty based on tonnage because in principle it is unreasonable, and in practice it comes hard on small mining enterprises. Some official fixation of the royalty would be a great relief to the Canadian mining industry, and we wish it were practicable on this side of the border, but we suggest that the Canadian government might do even better, by buying the disputed patent-rights, and then either make a present of them to the mining industry of the Dominion or else charge a small royalty, sufficient to represent 4% on the purchase. Such a step would serve at once as a strong stimulant to mining development.

## Making a Career

Mining makes demand upon a great variety of talent, and the successful application of that talent is conditioned by the vicissitudes inherent in the adventurous search for mineral wealth; so that the career of the mining engineer is not without a romantic element. He may climb from a small opportunity and attain to a big achievement; he may begin in a frontier camp and end in the seats of the mighty; above all, he may start under a big handicap and yet become a winner in the long race of life. This is true of other professions, particularly in this land of opportunity, but in mining it is linked to the great adventure—the opening of an Aladdin's cave under the crust of the earth. Several of the most notable men in our profession have achieved distinction despite the absence of those early educational advantages that they themselves have not failed to give to their own sons. We confess to sincere admiration for the force of character that can surmount an obstacle so fundamental. In this issue we publish an interview with a distinguished mining engineer in whose life natural abilities backed by tenacity of purpose have triumphed over the lack of a conventional education. Mr. W. J. Loring is a native Californian whose childhood was spent amid the muffled thunder of the stamp-mills. From the first he knew that men make holes into the ground to find the golden ore, which they then smash into powder in order to separate the gold from the worthless quartz or slate with which the precious metal is enveloped. Early he realized that the purpose of mining was to make money, and early he was impressed with the essential virility of the men that directed the technical operations. His reference to James Parks will be appreciated along the Mother Lode, for that worthy mine-manager was a notable figure in the foothill country and represented a type of man never common, combining good judgment, ready initiative, and sterling integrity. At an age when most boys have just begun their schooling Mr. Loring learned to hold a drill and to do the small work about a mine, following this with similar labor in a mill. One that has broken ore with a hammer and fed it with a shovel into a stamp-mortar will appreciate the automatic crushers and feeders of a later period. Personal experience in the benefits of mechanical development must stimulate an intelligent interest in labor-saving devices. Thus, in the years that followed, Mr. Loring helped to test and use various appliances that release human muscle for more effective service in the mine and mill. As a young man he worked with a progressive group of men. His experience in reducing the output from a pocket of specimen ore, in the Tryon mine, was useful in preventing him thereafter from becoming excited at the sight of free gold. By that time, when he was barely 20, he had attained a position of considerable responsibility and had the satisfaction of taking his part in the erection of the Utica mill, which was destined to extract several millions in gold. His chief, Charles D. Lane, was one of the last

of the old type of Californian miners; from him he got the zest for mining adventure, the prospector's love of underground exploration. As Charlie Lane used to say: "I am digging all the time, and praying like hell." He knew that he needed the aid of luck—every miner does—and if he went too often to spiritualism instead of science, like his associate Alvinza Hayward, yet he had that saving common-sense that is closely akin to science and through it he was saved from many of the stupidities into which spirit-rapping might have led him. Fortunately, Mr. Loring acquired the practical sense of these old Californians without being attracted by their mystical vagaries. In due time a call came for service in a larger and more distant field. He went to Australia, on the invitation of the Hoover brothers. It is a far cry from the young engineer in that mine-manager's office in Western Australia to the Food Administration's building at Washington, but the qualities manifested by Mr. H. C. Hoover 15 years ago are those that he is now using to such great purpose. Our readers will like Mr. Loring's reference to his former associate, through whom he obtained the great opportunity of his career. It enabled him to prove his mettle. Then, as now, he realized that the object of mining is profit, not low cost per ton or high extraction, except in so far as these are contributory to the main result. His early training made him a keen millman, but he realized that the major economies were to be made in the mine itself. He studied the cost-sheet, and kept his eye on the payroll, for 60% of the total cost of mining is labor. The success scored by him at the Sons of Gwalia marked him as a capable administrator. Here we may refer to the joint management of the Australian mines under the direction of Bewick, Moreing & Co. in 1903. We refer to this simply to lay stress on the inadvisability, to put it mildly, of such division of control. The experiment has been tried so often that it is no longer an experiment, but an assured failure. The reader will note Mr. Loring's part in starting the smelting of the ancient Chinese slag-dumps at Bawdwin, now identified with the important enterprise of the Burma Mines company. The story of his reconnaissance at Porcupine, in its early stages of development, is likewise interesting. We ask the younger men to note again the injury done by malaria. In Mr. Loring's case it was slight, but the mention of it gives us the opportunity once more to advise young men not to sell their birthright—good health—for a mess of pottage—an increase of pay. We would like to dwell on Mr. Loring's remarks concerning the British administration of mining companies, but space will not permit. The publicity given to operations and the protection given to shareholders are admirable, but the red tape, figure-head direction, and flux of responsibility are points of obvious weakness in the British system. After engaging in professional work around the world, Mr. Loring has returned not only to his native land but to the very mining region in which he made his start. By his successful re-opening of several mines on the Mother Lode he has proved that a proverb can be read back-

ward as well as forward, for he is held in honor even in his own habitat. He has retained the qualities early ingrained, the love of mining itself; "he likes to dig," as Charlie Lane said; he is keen on milling, now supplemented by flotation; he is kind to workmen and is liked by them, so that he can get the best out of them; while climbing the ladder of professional success he has not lost the sense of comradeship and the sympathetic touch that makes the ideal employer and manager. We note his own regret that he missed the educational opportunities that he has taken care to give to his promising son, but to this day his judgment of a mining venture is better than his technical description, which exemplifies the dominance of the practical over the theoretical in his mental development. The same utilitarian sense may be acquired by men of full technical training that, in the spirit of ambitious apprenticeship, have not hesitated to learn the business details of mining after graduation from college. The point is that Mr. Loring does not belong to that class of so-called self-made man whose boast is that he has dispensed with technical training. The question arises whether such men as Philip Argall, J. H. Mackenzie, D. M. Riordan, and W. J. Loring, successful engineers whom we have interviewed and who have told us how they overcame the lack of a conventional education, would have done better if they had been better equipped at the start. The answer cannot be made confidently. The handicap spurs the runner, the absence of equipment and patronage necessitates special effort, under which the best qualities of the man may have the best chance to grow. If similar force of character could have been developed along an easier trail, it is likely that the educational help would have been turned to good account. To a mining engineer a college training is a short cut; by aid of it he can learn more rapidly and think more logically than the man not so assisted. He fails often because his essential manhood has not been trained with the severity that marks the life of his less favored comrade, who has to depend entirely upon native intelligence, pertinacity, courage, and opportunity. It is fair to judge a man by what he has achieved. We respect the man that makes the most of his opportunities. It is more than delightful, it is inspiring, particularly to the young, to see men overcome the limitations of their environment and prove that strong character is not to be held down by the fortuities of place and surrounding. Possibly the consciousness of limitations is less oppressive in a mining camp, for instance, than in a great city. The man who deals daily with a great variety of persons unequally educated has a better chance of becoming conscious of mental power, and is encouraged thereby to forget his own handicap; he is encouraged to overcome that handicap and to place himself on a level with those that have undergone a special education, to find, if he persevere, that their accidental advantage over him is less decisive than the natural capacity with which he was born. Thus mental power and essential virility enable men to conquer circumstance and achieve their purpose, which is to be happy and effective.

## Mill-Tests v. Hand-Sampling

The Editor:

Sir—I have read with great interest the 'combination method' of sampling large low-grade orebodies devised by Morton Webber which appeared in your issue of September 29. I think all engineers who have studied the latent difficulty in estimating what the true mill-heads of a large deposit will be when the ore is mined, will feel that Mr. Webber's system marks an important advance in sampling and in the general technology of the subject. I am one of the losers in the Alaska Gastineau venture, but I decidedly agree with what you say editorially, that the loss of over \$15,000,000 of public money was "not due to chicanery, but an ineffectual attempt to ascertain the real gold content of large masses of low-grade ore. Let us learn by experience." After considering the matter carefully, it is difficult for me to conceive how Mr. Webber's method, if applied to this case, would have failed at a comparatively early date to disclose what would have happened when the supposed ore reserves were stoped on a commercial scale. Mr. Webber's system seems to have as its object the utilizing of the chief benefits of moil-sampling and mill-testing, and the elimination of their relative defects.

The defect of moil-sampling, as is well known, is that it has a latent sampling-error which, prior to Mr. Webber's method, could not be estimated until the ore was mined, or in other words until 'after the horse was gone.' The defect in the mill-test is that it only accurately samples the particular place from which the ore is removed. To use a chain of mill-tests to determine the sampling error, as in Mr. Webber's method, and to correct the hand-sampling of the ore-reserves by using the mill-test as a "sampling-error indicator" for various zones, is in my judgment a radical improvement. If this system was properly applied to any large low-grade ore deposit, it would be difficult for me to understand how responsible people could be misled. The main thing would be to properly apply the system to a particular case. This would require judgment and experience, but that it could be applied I am confident, the principal item being expense. The mining profession had to have, as I suppose, the 'rap over the knuckles' of the Alaskan experience, and I do not think any ill feeling has resulted. I think sufficiently well, however, of the 'combination method' that there should be no excuse for a second failure. The question, however, that requires further clarification in my judgment, is the size

of the zone that should be corrected by the sampling-error mill-test conducted within it. Mr. Webber states, "the size of each individual zone will depend on the nature of the ore. In this way it may be possible to divide any ore deposit into zones, to be governed by the engineering expediency of the particular case. The principles of this 'combination method' will apply to the best advantage on mines of fairly uniform mineral characteristics. The greater the variation the shorter must be the distance between one mill-test point and its neighbor, and the reverse." While the excerpt here quoted deals with the principles that should govern the size of the mill-test zone, the means of determining the size is open for discussion. Obviously the personal factor must be introduced. On thinking over the most practical method of deciding upon the size of the zone, I suggest if it is intended to put in a 'chain' of mill-tests, I should recommend that the variation of the sampling-error between one mill-test and its neighbor should be the governing factor on deciding on the area of the zone. Whether the sampling-error is large or small should not be a factor in this decision. A mine indicating a fairly uniform sampling-error of 40% could stand obviously much larger zones to each mill-test than a mine where the sampling-error fluctuated from zero to, say, 20%. So, I think, we may take it that the degree of sampling-error is not the deciding factor in the area of a zone, but the fluctuation in the sampling-error between one mill-test point and its neighbor.

To apply this method to meet the underlying principles I will suppose a main development-drift being driven along a large low-grade orebody. At a certain point a sampling-error mill-test 'A' is instituted from the roof of the drift. The sampling-error here is found to be 20%. Another point, say, 400 ft. from the first test, is subjected to a mill-test, which we will call 'B,' and an error of 25% is obtained. I feel confident that a factor for the average of A and B would properly govern the hand-sampling of the intervening space. If a third test 'C' was instituted 400 ft. farther along the drift and the error proved to be 40%, showing a violent fluctuation from B, a mill-test should then be made between B and C, dividing the intervening distance into two blocks of 200 ft. This is probably what Mr. Webber had in mind when he stated, "It should be possible to divide any ore deposit into mill-test zones depending on the engineering expediency of the individual case." I feel, however, that it is most important that the application of his system should be discussed. In former cases,

where the mill-test has been employed as a means of sampling, and not exclusively as a sampling-error indicator, as in the 'Webber method,' a large amount of ore was mined and treated from a relatively small number of places. This meant special expense and exploration for the purpose of sampling. Also the expense of a mill was entailed before it was known if the mine would be a success or otherwise. The numerous small mill-tests used as sampling-error indicators in the 'combination method' could be made from the development openings of the deposit, and much expense would be avoided.

The great benefit, in my judgment, of Mr. Webber's method is that the actual mill-heads of large-scale operations can be determined as the property under exploration is being opened up. All former systems failed to do this. A large investment of capital was involved before this was ascertained. Therefore a method that can disclose the true mill-head for each zone as it is developed is unqualifiedly a radical step in the sampling of large low-grade ore deposits.

New York, October 1.

R. E. RAYMOND.

The Editor:

Sir—While reading the valuable contributions from Morton Webber, and others, on mine-sampling methods, the thought occurs to me, as it has done heretofore, that there is not enough common ground for the mine-sampler and the one who excavates the ore. The miner is depended on to make good the computations, estimates, surveys, sampling, and other preliminaries to his final labor. Sampling, whether by moil or mill-test, is mining in miniature. In taking his samples, making his measurements and estimates, the engineer should visualize what will happen when the stoping is done, whether or not the miner will take out the ore that was sampled in a way represented by the sampling-process. The same stope under different administrations will produce entirely different grades of ore, depending, first, upon the industry and skill with which the workers perform their task, and, secondly, upon the character of the ore. If the ore is short, and labor is scarce and incompetent, the ore, excepting what is carelessly lost by reckless blasting and imperfect methods, will go into the chutes accompanied by a lot of waste, both from waste inclusions in the vein and from the wall-rock; on the other hand, if the ore breaks big and clean, the careful miner is glad to be able to sort out the refuse, as the waste helps to support his stope, and to prepare it to properly care for the next blast and to prevent scattering and loss. The ore from such an administration will not only be of higher grade, but more actual metal will be won. Again, ore slabbed off from the sides of drifts by machine-drills will not give the same mill-feed as material from the same orebody when caved in large masses, mixed unavoidably with waste from included bodies and the wall-rock. My point is that ample regard must be had, by the sampling engineer, for the conditions under which the ore actually will be produced. Small-scale mining,

or sampling, must not assume conditions of perfection not attainable in every-day work.

Kellogg, Idaho, October 4.

STANLEY A. EASTON.

## Water and Mines in Paradise

The Editor:

Sir—In your issue of September 29, 1917, Ivan E. Goodner, the chief of the Paradise irrigation district, takes exception to some correspondence sent in by me to the MINING AND SCIENTIFIC PRESS for a previous issue. In the interest of your periodical, whose correspondents are generally reliable, I must take exception to some of Mr. Goodner's remarks. They are not only inaccurate but untrue. After an opening remark or two the statement is made that "The following is a correct statement of the matter." My understand of the word 'correct' is possibly different from that of the young engineer. The first statement is that "None of the owners of the land referred to has so appeared at any time in the past, but all have paid the tax levied without protest." How about the Mineral Slide Mining Co., in Sec. 10, T. 23 N., R. 3 E., M.D.M.? Mr. Goodner not only protested, but forced withdrawal of their property from the irrigation district. Statement No. 2 is: "The land in question includes 20 acres which is susceptible to profitable orchard development, etc." The land in question includes 54 acres, not 20, and the tax levied was \$5 per acre instead of \$1. Next year's tax will be \$1. The young engineer should correctly inform himself of these things before rushing into print. As for "profitable orchard development," I am not a farmer, but if a lava scarf at an angle of from 35 to 65° will support a "profitable" orchard, I have that thing to learn.

The last paragraph of the statement is as follows: "To make the matter short, it is not true that the district is levying an unwarranted tax upon mining land; it is not true that the owners pay tax without being allowed to have the water, and it is not true that the mines are being deprived of water to which they have a right for mining use." In answer I will cite one case, that of the Lucky John mine in the N.  $\frac{1}{2}$  of Sec. 11, T. 23 N., R. 3 E., M.D.M.; 54 acres of this property was included in the irrigation district on which the tax has been paid. As no water may be used for mining purposes, it is obvious that the Lucky John mine will get no water. The miners are being deprived of water, as witness the damage suit now pending in the court of Butte county between the Mineral Slide Mining Co. and the Pacific Gas & Electric Co., that sold only their "right, title, and interest" (not grant, bargain, and sale) to the Paradise Irrigation Co. The two ditches that supply Paradise with water were built originally by mining men, Delaplain, Nickerson, Moody, and others, for mining purposes only, and later sold to the Oro Light & Power Co., the original owners retaining certain rights.

J. D. HUBBARD.

Paradise, California, October 2.

## Methods of Mining

The Editor:

Sir—The reading of your series of articles on the Miami methods of mining was a pleasure and brought to my mind the thought that the evolutionary steps that have made possible some of the mining methods used in the winning of large copper deposits might be of interest to mining engineers. Unfortunately, it is not possible at this time to trace the historical evolution, and indeed it would be an extremely difficult matter, since the historical record is fragmentary and spread through the mining lore of a number of countries. What I have to contribute is more the piecing together of older methods in an endeavor to show how the present practice could have been developed logically from a consideration of the essential features of well-known methods.

The room-and-pillar method is a system evolved from the primitive plan of mining coal in irregular chambers. As applied to thick coal seams it enabled a goodly proportion of coal to be won, but when applied to narrow seams the tonnage output was greatly restricted. Under difficult roofs the method was objectionable. These two considerations undoubtedly caused the development of the long-wall system. The application of this method taught mining engineers that it was not necessary to support the roof where it was extremely difficult to do so and that the better way was to allow it to subside. The use of the method gave skill and familiarity with working under heavy roofs. The winning of all the coal on the 'first working' was a particularly desirable feature. With the application of the room-and-pillar method to deeper and deeper coal beds the necessity for winning a greater proportion of the coal, in order to distribute the investment in deep shafts and more expensive hoists and other equipment over a larger tonnage, became apparent. The greater earth-pressures caused engineers to use wider pillars and narrower rooms; this naturally reduced the proportion of coal won. Under the stimulation of these necessities the bord-and-pillar method was evolved. In this method the coal bed is divided into large square pillars by a rectangular system of galleries. Each pillar was mined by a modified long-wall method. Instead of attempting to carry a long-wall face, by mining progressively from the 'gob' to the 'solid,' slices were removed and the roof caved before removing the next slice. The initial cut was made close to the gob, but with a protecting pillar between. The coal was then mined up to the gob, props being used to give temporary support. When the limited area was mined the props were blasted out or removed and the roof caved. Fig. 6 on page 421 of your article illustrates a sequence similar to that used in mining a pillar of coal by the plan just described. Top-slicing is thus traced back to the methods of mining coal. The evolution of the timber mat came in response to the need of a method for mining extensive thick orebodies. The bord-and-pillar method could be applied to the first slice, but was limited in the thickness of the slice by the height of

the available props. Working under loose ground was effected by fore-poling. This was applied to the mining of the second slice, and with succeeding slices the miner undoubtedly discovered that the caved timbers of the slice above gave considerable support, becoming a distinct advantage. It was a simple step to the recognition of the desirability of forming a thick mat of timbers as a protection against sudden runs and the control of the top pressure. When these essential ideas had been developed, systematic application followed as a logical evolution and in the application of top-slicing on the Mesabi and at Miami the method reaches its full development.

The beginning of shrinkage-stoping can be traced back to overhand stoping. Either the substitution of waste-filling and the attack of the back from the top of the waste-pile, or the piling up of the broken ore upon the bottom of the stope and the use of the pile as a platform, must have suggested to the miner the filling of the stope with broken ore as a substitute for supporting-timbers and working-platforms.

The application of shrinkage-stoping was in response to a demand for a method that could be applied to wide orebodies and that would avoid the expensive square-set system or waste-filling. A primitive method of mining magnesite came under my observation some years ago and is of interest in this connection. The magnesite occurred in a network of small veins in a vertical zone of serpentine 40 ft. wide. The stope was opened out on an adit-level for the full width of the zone. The miners broke down all of the material and selected the white magnesite, leaving the serpentine as a filling and also as a platform from which to reach the back. Enough serpentine was trammed out to give a working-space between the back and the top of the pile. The method was undoubtedly a wasteful one, you will say, but it shows how the miner makes use of the obvious and most direct means even at the expense of valuable mineral lost. The combination of top-slicing and shrinkage-stoping in the systems used in the South African diamond mines illustrates the readiness of the engineer to invent new ways out of old ones.

Block-caving can be traced to the method of under-cutting an earthen bank and to under-cutting a coal seam in long-wall mining. In a stone-quarry the under-cutting of the toe of the bench and the wedging of the overhanging rock-mass may be considered as a further development. The excavation of a high bench, 150 to 200 ft. high, by first driving galleries into the bottom and then cross-galleries in order to support the mass on pillars, is similar to the methods used in underground block-caving. The reduction of the size of the pillars and the final removal of them by blasting parallels the case in most of its details. While both of the above methods of quarrying are obsolete, in the application of underground block-caving in the Pewabic mine the method just described was followed, with the additional feature that the ends of the block were cut off by open

stopes. At Cananea the block was surrounded by shrinkage-stopos; and in this example we have the first combination of the two methods. The application of shrinkage-stopos separated by narrow pillars to the bottom of the block in place of a system of pillars and galleries was the next development and is described in your article. In the Pewabic mine the caved block was removed by fore-poling drifts driven into the loose pile. Necessarily a large amount of shoveling ensued and the application of a system of chutes and the substitution of chute-loading for shoveling, all of which had been worked out in shrinkage-stopping, was to be expected. At the Ohio mine the system of collecting-chutes was worked out and a similar system was adopted at the Miami. Thus the method at Miami represents a combination of advantageous features developed in other mines. This is good engineering.

GEORGE J. YOUNG.

San Francisco, October 21.

## Mill-Tests v. Hand-Sampling

The Editor:

Sir—Bearing in mind that the object of sampling generally is to ascertain as closely as possible the metallic contents of some specific orebody, and bearing in mind that the expense of doing this must be as small as possible, we find ourselves between the two extremes, that of taking out the whole block and putting it through mill or smelter, or that of taking a single small hand-sample to represent the whole mass of ore. Obviously neither will be done, some middle course will be followed by which we shall secure the maximum information at the minimum expense.

How much information we gather, to what expense we go, whether we trust entirely to moil-samples, to mill-samples, or to a combination of both of these, will depend upon the many factors entering into the problem of examination, its object, and the results as exposed from time to time.

We can say little of the merits of Mr. Webber's method or that of Mr. Jones or Mr. Smith unless we have a concrete case on which to apply it, some case where it is particularly applicable or particularly inappropriate, but this we can say: any suggestions that make for increasing accuracy in mine-sampling are appreciated. We store them away in the backs of our minds and some day they become useful in a particular case.

Mr. Webber's method, though he speaks of a mill-sample, is, as he himself admits, not a mill-sample at all. What is it then that he does? He samples a face with a moil as closely as the nature of the ore warrants, he puts in a light round of holes, breaks out a foot in depth, samples again, breaks out another foot, and repeats the sampling and breaking once or twice more. All of the material shot-down he crushes fine enough to pass a mill-screen and samples the crushed material thoroughly. He is then able to compare the average result of a large

number of moiled samples from one point in the mine with a single sample taken a foot deep from directly under his moiled trenches.

If the large sample shows a different percentage of metal from the average of the moiled samples, he corrects all of the moiled samples in that part of the mine by a corresponding plus or minus factor. This will be a safe rule to follow, only when the engineer's good judgment tells him to what area he will be safe in applying such correction. It will not be a panacea for all large low-grade deposits. Every deposit is a problem in itself, presenting some new factors, requiring ingenuity, skill, and experience to solve satisfactorily.

Whether the idea is new or not I do not know, but it is new to me, and yet I have done pretty nearly the same thing on more than one occasion. I recall a rather low-grade, wide, oxidized silver-bearing vein in Mexico. I had moiled a series of trenches for 100 ft. in the back of a drift, found them to check with a previous sampling, but had some fear lest the moiling was shattering an excessive proportion of brittle oxidized silver-bearing minerals. As there were several thousand feet of drifts and cross-cuts to be sampled, I selected two such places as mentioned above and shot-down from the roof of each of the two 100-ft. sections between 125 and 150 tons. These two large samples were crushed and quartered as in any ordinary sampling-mill except that the first breaking was down to about  $\frac{1}{4}$ -in. mesh. The results happened to check quite closely with the average of the moil-samples, so closely that I thought they required no correction. If they had been different, I might have used such a factor to correct my moil-samples as Mr. Webber used. In this instance it could have been done to advantage had there been an appreciable difference.

My personal experience with large low-grade deposits has not been so extensive as to warrant my laying down any rules. It so happens that in my own work I have been fortunate in having such large and low-grade deposits as I have examined and sampled by moil check out fairly well in the mill. My own troubles have been with the small higher-grade and erratic veins. Here I have found serious discrepancies, but they were not such as to have been reduced by Mr. Webber's method or any other method short of taking out all the ore.

Permit me, through you, to express my thanks to Mr. Webber for the suggestion he has made, a suggestion that may be very useful on some future occasion in my sampling career.

F. F. SHARPLESS.

New York, October 8.

METAL industry in California is increasing greatly under the stimulus of the War. The chrome output in 1916 jumped from a value for the previous year of \$38,044 to \$717,244, and the contrasting figures for magnesite were \$283,461 and \$1,311,893 respectively. Quicksilver also grew from \$1,157,449 to \$2,003,425, and manganese from \$49,098 to \$274,601.

THE SONS OF GWALIA MINE, IN WESTERN AUSTRALIA

## W. J. Loring. A Californian Engineer

AN INTERVIEW. By T. A. RICKARD

*Mr. Loring, you are a native of California, are you not?*

Yes; I was born near Half Moon bay, in San Mateo county, California, on March 6, 1869.

*Was your father a mining man?*

No; my father was a lawyer, and came from Illinois. On his side my people were French and English, and on my mother's side they were Dutch and Scotch.

*What schooling did you have?*

A common-school education in Amador county.

*Then your father moved to Amador county?*

Yes; the family moved to Amador county in 1879.

*So you were brought up among the sound of stamp-mills?*

Yes; there were a number of stamp-mills in operation at Amador City, where we lived, at that time.

*Have you any early recollections?*

I recall James F. Parks, Sr., who was underground foreman of the Keystone mine; and I also remember distinctly when he left the Keystone and took charge of the Kennedy mine. As a boy, his long legs impressed me, and I often wondered whether I would ever occupy as exalted a position as Mr. Parks. My family remained in Amador City for about three years. At that time the Original Amador operated a 40-stamp mill, and I remember when it was closed down. The Bunker Hill was also operating a 40-stamp mill on Rancheria creek. As a boy I was impressed by the activity around these mines, and particularly the noise of the hoisting-plants. When I was about 12 years of age a man named Collins, who was then employed as a miner in the Keystone mine, owned a claim called the East Keystone, which happened to be close to my home; his assessment work consisted of driving a cross-cut into the side of a hill. It was here that I began my mining career, turning a drill and doing such work as a boy of twelve could perform when not at school.

*You found that more interesting than books?*

Mainly for the reason that I was paid at the rate of

50 cents per day to begin with, then 75 cents per day, and my pay-day was every second day.

*When did you leave school and begin your career?*

From Amador City my family moved to Plymouth, in the same county, and when not at school I was employed intermittently breaking ore with a hammer and shoveling it into the feeders in the old Empire mill. There were no rock-breakers except one at the South shaft, but this was usually out of order.

*When did you begin regular work?*

At the age of 14, at Plymouth. My first responsible job was taking care of 16 Tulloch feeders in the old Empire mill, belonging to a property which is now part of the Plymouth Consolidated. From the feeders I was gradually promoted to be assistant-amalgamator and concentrator-man, until the mine took fire on January 26, 1888, when the property was closed down by the owners. These were Alvinza Hayward, Walter Hobart, Sr., and their Eastern associates.

*What did you do next?*

John E. Reaves, who was foreman of the Empire mill, took a fancy to me as a boy, and when operations ceased at Plymouth, he was transferred to the Utica mill, at Angels Camp, then under option to Alvinza Hayward and the elder Walter Hobart. Within a month after his arrival at Angels Camp he secured for me a job in a 10-stamp mill owned by George Tryon, Walter Tryon, Thomas Hardy, and James McCreight, at Albany Flat in Calaveras county. I was then 19 years of age. The Tryon mine, as it was then known, was producing very rich ore—so rich that it was possible to pound out \$200 to \$500 per day in a hand-mortar. The ore that was stamped yielded from \$30 to \$60 per ton.

*So you must have got credit for being a good millman?*

Evidently I was considered a good millman because when I first went to work I was put on the day-shift and remained for one week, when I changed to the night-shift; but Walter Tryon, the superintendent, thought

so well of the improvements that I had made that he only allowed me to work by night for three shifts, putting me back on the day-shift, where I remained until the property was purchased by the Utica Mining Co. in the summer of the same year, namely, 1888. The mill was operated by a 52-ft. overshot-wheel, and, as is usually the case, water became short in the summer and the mill closed down until the winter rains. I was transferred to the Utica mill, then containing 20 stamps and under the superintendency of Charles D. Lane. Soon afterward the company decided to add 40 more stamps. During the re-construction of the original 20-stamp mill and the addition of the new 40 stamps, I was employed in placing machinery and doing whatever was necessary to assist in the erection of the plant. I remember distinctly having personally set the first tappets and also pounded on the first shoes that were used in the new mill on the Utica. I did that with my own hands.

*How long did you remain at the Utica?*

Until August 4, 1901. During the 13 years I rose to the position of assistant-superintendent of the Utica under various superintendents, including Charles D. Lane, his son Thomas T. Lane, E. L. Montgomery (formerly superintendent of the Plymouth Consolidated), Theo. Allen, and L. W. Shinn. I occupied the position of head amalgamator until April 30, 1894, when John E. Reaves was taken sick and died. I was then promoted to the position of mill-superintendent, in charge of 160 stamps, during which time the bonanza orebody in the Utica mine was discovered and worked, producing \$203,000 in one month.

*What made you leave the Utica?*

W. C. Ralston, with whom I had become acquainted, offered me the position of superintendent of the Melones mine at Robinson's Ferry, as it was then called. He offered me a considerable increase in salary, which I accepted, taking up my new duties in August, 1901. It had been decided, prior to my acceptance of the superintendency, to erect 60 of the 120 stamps then lying on the property, and to thoroughly equip it and put it into operation. During the following six months 60 stamps were erected, a dam was built in the river, together with a flume and ditches for the transmission of water to drive the 60 stamps and auxiliary plant. In January 1902 I received a letter from T. J. Hoover, who was then at Bodie, Mono county, asking me if I would consider an appointment as superintendent of a mine in Western Australia. This offer came from his brother, H. C. Hoover, who was then a partner in the English mining firm of Bewick, Moreing & Co. The terms of the offer were \$6000 per annum, and the contract called for two years and traveling expenses. This offer I declined. Later I was offered \$9000 per annum, with traveling and other expenses, which I accepted. I left San Francisco for Western Australia on February 9, 1902, going direct to Sydney, overland by train to Adelaide, and thence by steamer to Perth. From Perth I went by train to Kalgoorlie, where I met Mr. Hoover

and W. A. Prichard, who had previously managed the Keystone mine at Amador City, and whom I had known at that time. Mr. Prichard recommended me to Mr. Hoover. This was my first acquaintance with Herbert Hoover.

*What impression did he make?*

He impressed me first with his youthful appearance, for he was then only 27 and looked younger; but after several days' contact with him, he impressed me as being a very capable young engineer. He had a unique way of getting at the root of things without preliminaries, avoiding unnecessary detail. Then, as now, I do not believe that he cared for details. He appeared to have the faculty of getting at the essentials by eliminating non-essentials. I was entertained by Mr. Hoover and enjoyed his company for several days, prior to leaving for the Sons of Gwalia mine, which I had been engaged to superintend. Before leaving Kalgoorlie, Mr. Hoover told me that in his opinion 20 of the 50 stamps on the Sons of Gwalia should be closed down for a time to allow the mine to be thoroughly developed. I asked his permission to examine the mine before coming to a decision as to what should be done, to which he agreed. After looking over the situation I came to the conclusion that the mill could be run at full capacity and great improvements made throughout the whole scheme of operations. I had the Californian dislike of hanging up stamps, and I also believed that the mine was capable of producing sufficient ore to maintain the mill at full capacity.

*What was the result of your recommendations?*

I took charge of the mine on April 11, 1902, and on that day the mine payroll had 814 men on it. The mill was treating 8000 tons monthly, and the working-cost was 35s.6d. per ton; the output barely covered the cost of operating and development, being in the neighborhood of 50s. per ton. The mine had an ore-reserve of 60,000 tons when I took charge, and at the end of the year the reserve had been increased to 120,000 tons; a bank overdraft of £10,000 and an outstanding debt of £10,000, had been liquidated; in addition £46,750 had been remitted to London. The number of men on the payroll had been reduced to 420 and the working-cost reduced to 21s., the over-all cost becoming 35s. per ton.

*How long did you remain at the Sons of Gwalia?*

For about two years. On January 15, 1903, W. R. Feldtmann resigned as general manager for Bewick, Moreing & Co. in Western Australia, and Mr. Prichard and myself were appointed joint general managers in his place. The firm was then operating 16 mines in Western Australia, half of them in and about Kalgoorlie and the rest scattered. Among the latter was the Sons of Gwalia, and it was these scattered mines that I took charge of; while Mr. Prichard attended to the Kalgoorlie group.

*So you had much travel over the desert?*

Yes; I traveled about 30,000 miles a year among the

A GROUP OF WESTERN AUSTRALIAN ENGINEERS

Top row, left to right: G. W. Borrowe, W. E. Simpson, F. G. T. Nicholas, V. S. Allen, J. V. Jukes, W. R. Bawden, C. W. Skrine, E. A. Griffith, D. D. Sinclair, E. Graham Price, E. Günther.

Middle row: A. Sheard, H. A. Shipman, W. W. Johns, P. Ledoux, W. W. Barton, W. H. Turner, H. Lawrence Read, T. Maughan, Henry Cribb.

Bottom row: Norbert Keenan, W. J. Loring, F. A. Moss, G. M. Roberts, F. A. Govett, G. A. Touche, R. Hamilton, W. A. Prichard, J. W. Sutherland.

THE IVANHOE MINE, AT KALGOORLIE, WESTERN AUSTRALIA

various mines that were in my division. Some of the traveling was done under great discomfort, owing to the heat and dust. We did not use the motor-car until 1906. It required 64 horses to transport me on one of my round trips.

*How long did the joint general-managership last?*

It lasted 16 months. Mr. Prichard then resigned and I was left in full charge in Western Australia until 1906, when I was appointed general manager of the whole of Bewick, Moreing & Co.'s interests in Australasia. This included mines in Victoria, Queensland, New South Wales, Western Australia, and New Zealand. My headquarters were then at Melbourne.

*When did you become a partner?*

I took over Mr. Hoover's interest in July 1908, when Mr. Hoover left the firm; and soon afterward I took up my residence in London, so as to be with my senior partner, C. Algernon Moreing.

*When did you go to Burma?*

I arrived in Burma in that year, 1908. The purpose of my visit to Burma was to look over the properties of the Burma Mines, Ltd., which owned the Bawdwin silver, lead, and zinc mines. The Burma Mines company was organized to treat 110,000 tons of slag lying in the jungle, but the intention was not to re-open the mines, at first. It was necessary to build a railway 52 miles from the Government railway in order to transport the slag to the smelter at Mandalay. This smelter was operated for two years, during which time I made yearly visits to the property, each time becoming more impressed with the possibility of opening up an enormously rich lead and silver mine below the old Chinese workings. The history of this mine had been traced back to 1320, and during my several visits I found remnants of high-grade silver-lead ore mixed up with the slag; and judging by the enormous excavation in the mountain it appeared to me that large bodies of ore must have been extracted at an unknown period. After smelting operations had commenced, we started development work on a small scale, and almost immediately high-grade ore was encountered in the form of pillars and remnants in the old workings. This was in 1910. After operating the smelter at Mandalay at excessive cost, due to over 200 miles of rail haulage, it was decided to move the smelter to Nanttu, 12 miles by rail from the mine and 2500 ft. lower than the old excavations. I recall my connection with this enterprise now with keen pleasure, seeing that it has become one of the great mines of the world; and, curiously enough, the later developments and expansion have been done largely under the direction of my former chief, H. C. Hoover.

*Where did you go next?*

On my return to London from Burma, late in 1908, I paid a visit to the Gold Coast of West Africa, visiting most of the principal gold mines in that country.

*And you escaped malaria?*

No; I did not. I suffered from malaria for two years

after my return from the Gold Coast, and do not believe that I have ever fully recovered from the effects of it.

*I hope that the next mine that you inspected was in a healthier climate?*

It was. It is said that I have the distinction of being the first engineer to visit the Porcupine goldfield in the early days of its boom—in January 1910. I went to this district, which is in Ontario, to examine a mining claim that had been taken under option in my senior partner's name by Henry Van Cutsem, who accompanied me on my journey to Porcupine. I went from Toronto to North Bay, and from there to mile-post 222, now called Kelsey, arriving there at 11 o'clock at night with the thermometer below zero. We were dumped into the snow with a train-load of prospectors, food, and mining implements of all sorts. My party consisted of the brothers Henry and Noah Timmins, their two partners, and A. T. Budd and Henry Van Cutsem. The recent death of Van Cutsem I regret greatly. He was a delightful companion on that trip and I shall never forget his many kindnesses to me. We arrived at the Hollinger mine after 15 hours of sledding over a rough snow-road at nine o'clock at night. Our road passed across Porcupine lake, which was frozen two to three feet thick. We arrived there at about 8 p.m.; the night was cold and clear, the temperature ranging around 40° below zero. When we were half-way across the lake the horses refused to go forward, and upon looking ahead much to our amazement we saw wolves about a quarter of a mile away. We had only one gun in the party, this being a 32-calibre revolver. Messrs. Timmins, who knew all about wolves, would not let us shoot at them. After a consultation, it was decided to divide the party, one part to make a detour around the wolves, hoping by some means to frighten them away and thus leave a free passage for the team and sleigh. Upon making the detour we closed in upon the wolves and the nearer we approached the less did they appear to move. Upon closer investigation we found that what we had taken for wolves was a broken-down sleigh loaded with goods, which had been scattered about the snow, and which appeared to move about in the star-lit and snow-clad whiteness of this northern night. The following day an examination, such as was possible, was made of the Hollinger and surrounding claims, then covered with snow and ice. The outcrop could be traced; in many places it stood as high as seven or eight feet above the surface. I saw the first shot fired in the outcrop, which afterward became the main shaft of the Hollinger mine.

*What made you see wolves?*

The optical illusion. The eye sees motion when everything is perfectly still.

*Have you found any difference between English and American company methods?*

American companies would do well to adopt some of the methods employed by English companies. One distinctive feature is the publicity given to results

obtained and to general conditions at the mine. This enables a comparison to be made, thus avoiding the possibility of the management living in a fool's paradise. Publicity also keeps the management up to date, by inviting comparisons.

THE FIRST SHAFT SUNK ON THE IVANHOE LODE, AT KALGOORLIE

I am also a believer in the British custom of annual meetings of shareholders; it gives every shareholder an opportunity to hear from the directors a statement as to the many points of interest. Under the American system a manager or president considers himself too busy to give much consideration to the distribution of information to shareholders, whereas under the English system this is compulsory. The system is often called, by us Americans, 'red tape.' While it is burdensome at times at any rate it furnishes a record and there is less likelihood of serious mistakes being made.

*Have you ever attended a meeting of shareholders that made any particular impression upon you?*

I have attended many meetings, all of which to my mind were most useful, and some of which greatly amused me.

*What particular meeting amused you?*

I have one in mind that I shall never forget. This was the annual meeting of a company operating in Rhodesia. The property consisted of a concession covering many thousands of acres, upon which were several

mines. The parent company sold mines to subsidiary companies, ran mines itself, farmed and raised cattle, was interested in all the business that a company of this nature could develop. In the early days the company had a bright future; as time went on reverses

came, the shares fell, and shareholders became discouraged. This resulted in much mud-slinging at the annual meetings. I was present at one of these meetings, which was called for 1 p.m., this hour being fixed for the purpose of eliminating certain shareholders who thought more of their stomachs than they did of their business. However, the meeting was well attended and was presided over by a fine-looking old Colonel. His address to the shareholders dealt with the minutest detail of operations, and consumed over two hours. During this time such shareholders as had other en-

agements were compelled to leave, while a few went to sleep, but the Chairman rambled on, finally coming to the end of his speech and proposing the adoption of his report and statement of accounts. He asked the shareholders

W. J. LORING AT THE DOME MINE, PORCUPINE, IN JANUARY 1910

ers if they had anything to say before the resolution was put to the meeting; on this invitation six men in the front rows were on their feet at once. Each of the six in turn criticized the directors in the plainest language for mismanagement. While each speaker was trying to see

which could get the floor first and say the worst about the directors, an old gentleman—sitting next to me in the back row of the hall—who had armed himself with reports and statements of accounts for several years past, and who had become nervous during the long and tiresome speech of the Chairman, and had tried to gain the floor as each previous speaker resumed his seat, finally made up his mind to remain standing, and wait until all the others had finished vilifying the directors. The Chairman looked over the heads of the meeting and said: "Gentlemen I have heard the remarks of Mr. Blank and I can only say what he has said passed like water off a duck's back; if there are no further comments I will put the resolution to the meeting." Whereupon the old gentleman, who had been standing all this time, became quite excited, waved his hands (grasping papers) in the air like a wind-mill and said in a loud tone of voice: "Hold on—hold on— what do you suppose I have been standing here for, for the past hour, I want you to know, Sir, what I think of you and your co-directors,"—and he certainly did tell them what his opinion was, which would not look well in print.

Where it is possible for shareholders to meet directors of companies and criticize or give expression to their satisfaction for good work, there is certainly a chance for shareholders and directors to become better acquainted than under the American system, thus, I think, benefiting the company generally.

*What about your experience in the Hollinger deal?*

I have already stated how I went to Canada early in 1910 for the purpose of inspecting the Porcupine goldfield. I could see, after spending a few weeks at Porcupine and Toronto, that deals in mining claims were made in the most reckless fashion. Nothing less than spot cash would do. A group of mining claims was offered to me, at my room in the King Edward hotel, Toronto, for \$90,000 cash; as no reports had been made, and no work had been done upon the property I naturally turned it down. That same property was sold within two hours for \$140,000 cash, the deal being completed the same day. So long as a man had four stakes in the snow he could sell a claim for a tidy sum of money. The Hollinger, at the time of my visit, did not embrace the property that is now known as the Hollinger mine, but only a part of it, for the part next to Pearl lake was offered to M. J. O'Brien, who afterward gave up his option, so that the Hollinger people were able to amalgamate the O'Brien property with the Hollinger. However, feeling sure that Porcupine would turn out some good mines, I decided to return to London and advise my partner, C. Algernon Moreing, to form a company, with sufficient cash capital so that Mr. Moreing could go to Canada with at least £100,000 at his disposal to be used in any way that he saw fit. This was done, the Northern Ontario Exploration Company, with a capital of £500,000, being formed. Then £100,000 was called up and Mr. Moreing proceeded to Canada when the weather moderated sufficiently to allow an exami-

nation of the surface. I left for Australia and upon reaching Port Said I received a cable from our London office stating that Henry Van Cutsem, who had remained in Canada after my departure, had secured an option on the Dome mine, on behalf of my firm, under the following terms: We were to furnish sufficient cash to develop and equip the mine, the character of the development and equipment being specified. Out of the first profits obtained we were to reimburse ourselves for all of the moneys so expended, plus interest, after which the profits were to be divided, 60% to the owners and 40% to my firm. I thought so well of the Dome property that I cabled my firm strongly recommending that the terms be accepted, provided the property included the big outcrop from which the mine took its name, with enough ground to protect its dip and lateral extent; and I suggested that a reliable surveyor be engaged to check the lines. I proceeded on my way to Australia, expecting the deal to go through, but, much to my disappointment, when I reached Colombo a cable was awaiting me stating that owing to our heavy interest in the Maikop oilfield it had been decided not to exercise the option on the Dome property. Mr. Moreing eventually proceeded to Canada, to exercise his own judgment as to the purchase of other prospects. He was met at New York by Henry Timmins, of the Hollinger mine. By this time the Hollinger had been incorporated into a large company and Timmins's partners had also acquired a large number of other claims in the Porcupine district. It was decided between Messrs. Moreing and Timmins that a number of the Timmins holdings, outside the Hollinger, should be sold to a new company, which was to be formed by our firm, headed by Mr. Moreing. The terms and conditions of the sale need not be recited, but I may say that the Timmins people received a fairly large sum of money, together with a considerable share in the new company, which was eventually called the Ontario Porcupine Goldfields Development Co. This company was formed in London and the Northern Ontario Exploration Company took an interest in it. Mr. Moreing visited Porcupine and inspected the Hollinger mine, which had then reached a depth of 200 ft., where rich ore was being exposed. On the day of Mr. Moreing's departure from Canada, Mr. Timmins agreed to sell 50,000 Hollinger shares to the Northern Ontario Exploration Co. on the understanding that these shares should be taken to London and a market made for them there. My firm was appointed transfer-agent for the Hollinger company. The price per share, I believe, was \$4. Mr. Moreing arrived in London in due time and the developments in the Hollinger continued most satisfactorily. As is well known, a market cannot be made in shares by holding them in a safe; the price of the Hollinger shares actually moved up, and the Northern Ontario Exploration Co. assisted the market by disposing of its shares and generally dealing in the shares of the company, finally disposing of its holdings at a considerable profit. The sale of the shares necessitated the signing of the share-certificates

W. J. LORING ON HIS WAY TO MINES ON THE GOLD COAST OF AFRICA

TERMINAL OF RAILROAD TO THE BAWDWIN MINES, IN BURMA. ON THE PLATFORM ARE W. J. LAKELAND, MRS. LOVELL, M. W. MORRIS, MRS. LORING, AND GERARD LOVELL

by my firm, acting as transfer-agent. These certificates finally found their way to Canada and we—as a firm—were severely criticized for selling our shares to the Canadians at a considerable profit to ourselves. As a matter of fact, my firm never owned a solitary Hollinger share. This I say with considerable bitterness, as I believe we, personally, should have been large shareholders in it. We could not have made a market in the shares of the Hollinger company without selling, neither could the transfer be made without our signature, acting as transfer-agents in London for the Hollinger company. We stood the brunt of all the mud that was slung, without having made one solitary cent out of anything Canadian.

*Have you—after your long absence from California—anything to say regarding your operations and conditions generally on the Mother Lode?*

I have a high opinion of the Mother Lode as a mining region; I believe that many improvements can be made, especially on the metallurgical side. It is not necessary for me to express any opinion regarding continuity in depth, as there are mines on the Mother Lode that have already reached nearly 5000 ft. on the dip, with a splendid showing in the bottom. I believe that the application of flotation to the treatment of certain types of Mother Lode ores will simplify the treatment, as well as improve the extraction of the gold contents of the ore. My belief is based upon results obtained both in an experimental way and on a practical scale. I believe amalgamation to be unnecessary, in many cases, as the results that I have obtained have proved that on a \$5.24 ore, 33% of which is free gold, a 98.3% recovery can be obtained by straight flotation. The tailing-loss is 10c. per ton. I do not believe that flotation can be applied to all ores on the Mother Lode, but I believe that important developments in the treatment will follow shortly after we have completed our mill, which is to be erected on the Dutch-App mines, in Tuolumne county.

*You must be pleased with the development of the Plymouth Consolidated?*

I am proud of the fact that I was personally responsible for the re-opening of the Plymouth Consolidated mine, which has up-to-date produced a profit, over all expenditures, of \$630,937 in a period of 36 months. As you are aware, I worked at the Plymouth as a boy and remained at the mine until it closed down, on account of fire, in January 1888. It was then operated by Alvinza Hayward, Walter Hobart, Sr., and their Eastern associates.

*Mr. Loring, you are married?*

I am; I was married to Miss Marie Ellen Everhart, at Angels Camp, California, on December 12, 1888. My wife has followed me in all of my wanderings.

*You have a son?*

Yes, my son Edward Amos Loring is a partner in our firm and at the present time is in London attending to the engineering department of our business.

*You are still an active member of Bewick, Moreing & Co., although you live in San Francisco?*

I am, I am pleased to say.

*Why have you changed your residence from London to San Francisco?*

The change is only a temporary one, I hope. Before the beginning of the War I came over from London to see the new mill at the Plymouth Consolidated begin operations; the intention being to proceed from California to Japan, Korea, China, and back to London through Siberia. I visited the Far East, but, owing to the War, decided not to return to London through Siberia, but to return to the United States; and as my partners were willing to take care of the London business, during my absence, it was decided that I should remain in the United States for the time being, to build up a branch of our business in this country. I have been enabled to start several promising enterprises, financed by my personal Boston friends, and these will keep me here for some time.

*When were you in Korea?*

The latter part of 1914. I visited Korea for the express purpose of looking over the properties controlled by my friend, Mr. H. Collbran. He has developed a unique mining proposition in Korea, on the Suan Concession, and is at the present time operating what is known as the Suan and Tul Mi Chung mines. Since my visit he has opened another mine which gives promise of being a very good producer. Fortunately, his rights antedate the Japanese occupation and he is able to operate under their friendly protection.

*What advice would you give to the younger men, or to their fathers, in regard to the preparation for a mining career?*

My advice would be the same as I gave to my son when he was preparing to enter the university at Sydney, and that was to select certain lines of study that in his opinion would be most useful to him and to avoid a smattering of many subjects; also, as far as possible, to mix with his university education the practical side of mining during vacations. The result has been that while my son is barely 27 years of age he has considerably more experience than many mining engineers 10 years his senior. I most certainly advise young folks to gain as much education as possible, and not leave their future to the mercy of experience as a teacher. Experience is as necessary as schooling, but it is slow and uncertain. Some men have made a mark in the world without a college education, but it is becoming more difficult as time goes on to accomplish great things without a special training. After a man has reached middle age and has had varied experiences he may be considered educated. Much depends upon the man and much depends upon the circumstances surrounding the man as to his success or failure in life. An educated young man has a great start over an uneducated young man.

# Principles Governing Zinc-Ore Deposits

By FRANK L. NASON

It is not my aim to discuss synthetic considerations only, but to discuss from an analytic standpoint also the effect observed on fissures, contacts between sedimentaries, contacts between sedimentaries and eruptives, including dikes, sills, and batholiths, and contacts between eruptives, in relation to the origin and genesis of zinc ores. For many years the term 'true fissure vein' has been a catch-phrase of promoters, and it has proved alluring to men with money to put into mining. The proof lay in the results of development; if an economic orebody were found, it was a true fissure, otherwise not. Instances of fissure veins bearing zinc that have proved highly remunerative are the Butte & Superior in Montana, the Interstate-Callahan in Idaho, the Broken Hill in Australia, and the Bawdwin in Burma. Fissure veins which are known to exist, but which generally are not economic, are found widely in Tennessee, Virginia, and in St. Lawrence county, New York. Many other examples could be cited. In Butte, Montana, the Butte & Superior and the Elm Orlu are probably part of the great Rainbow lode on the western end of which are the Alice and the Moulton. This lode, like the copper lodes farther south, is a great fracture in the monzonite or granite batholith. The vein in the main evidently is not a clean sharp break, but seems rather to be a fault or fissure-zone of brecciation. The zone was the channel for an intense circulation of water. The term 'intense' is deliberately chosen, since the extensive leaching of the more soluble salts from the original rock seems to warrant it. Furthermore, the silica of the original web appears to have gone largely into solution, and to have been re-deposited in the more or less colloidal gangue of the lead and zinc sulphides. The assumption that the silica gangue was derived largely from the silica of the crushed rock is somewhat arbitrary but not wholly so. Judging from the fact that the productive area of the vein widens and pinches on the strike while the lode matter does not, as a rule, follow the varying dimensions of the vein; and that where the vein and the colloidal gangue is thin or disappears, rotted rock with grains of silica takes its place, the conclusion is inevitable that intense circulation in the lode was confined to channels in the crushed zone.

A study of other fissures in the Butte district affords additional confirmation. Many fissures, even in the productive area, wholly lack the silica crusts, the vein-matter consisting entirely of rotted kaolinized feldspars, the original quartz grains remaining unchanged. Other veins in the district, fissures in every sense of the word save for the presence of minerals in economic quantities,

have colloidal silica developed in varying amounts. Another striking example of a crushed zone in which varying intensity of mineral circulation is to be noted is in the Animas Forks district in Colorado. The vein boldly outcrops for two or three miles. At one end is the Sunnyside, at the other the Gold Prince mine. Between these two the vein is 50 ft. thick or more. There are found small pockets or lenses which hold zinc sulphide in colloidal or even crystallized quartz. The mass of the vein, however, consists of partly digested fragments of the country rock, feldspar, quartz, and epidote, seemingly carried to a stage of incomplete solution resulting in a pasty mass, fragments of the original rocks, fairly sharp in outline having pasty rims and cores wholly unaltered. The Interstate-Callahan is undoubtedly a fissure or fault. For the most part the exposed portion of the vein which was being worked on my visit showed one wall to be of quartz monzonite and the other of Pritchard slate. Here the vein-matter seemed to be derived wholly from the slate. Both in the Butte and in the Coeur d'Alene districts, minor veins or fractures were noted, some mineralized, others not; with clean sharp walls and no filling of rotted rock.

In eastern Tennessee I have traced undoubted fissures, though not continuously, for ten miles or more. The fissures on the Goin and Caldwell farms, to be specific, were clean and sharp, and were from a fraction of an inch to 18 in. thick. The vein-matter below the influence of weathering was frozen to the wall-rock on the contact and the country rock was wholly unaltered and unmineralized. The depth on the fissures showing these conditions was proved by diamond-drills to a depth of 200 to 1200 ft. below sea-level. Another characteristic of these narrow but persistent fissures was the continuous mineralization. Where the fissures were exposed by washing off the surface soil, however thin the fissure, it was found to be filled from wall to wall with either zinc and lead or with zinc alone. That these were true fissures is shown by two facts: first, the fissures were followed downward through dolomite into slate; and second, the fissures cut across the line of strike of the country-rock. In four widely separated localities, Lead Mine Bend, The Welch, Lynch, and Russell farms, the fissures displayed additional characteristics. Between parallel fissures the ground was considerably brecciated, and in the New Prospect mine the breccia was extensively mineralized with both lead and zinc. In the other three localities, while strong mineralization appeared in the surface-breccia, no development work has been done to prove depth. In the townships of Macomb and Rossie,

St. Lawrence county, New York, a remarkable line or series of fissures is developed. This was extensively worked for lead seventy years or more ago. There can be no doubt as to the nature of these deposits. The fissures are vertical; they cut across the line of strike at an angle of  $60^{\circ}$ ; they traverse the white limestone and the gneisses which are interstratified with the limestone. They are sharp-walled, that is, no mineralization extends into the walls, nor are the wall-rocks changed, even when they consist of limestone, nor are the limestone or gneiss-fragments altered in the slightest degree. There are no metamorphic minerals either in the veins or in walls; these are as conspicuous by their absence as in the fissures in Tennessee. In both, however, fluorite is present in limited quantities. The fissures in Rossie and Macomb differ in their main essentials from the zinc deposits which so far as now known extend from Sylvia lake to the Northern Ore mines at Edwards. The Rossie and Macomb are cross-country fissures, those of the Edwards belt are seemingly strike-faults or fissures, parallel to the dip as well as to the strike. In Macomb and Rossie the galena and blende are in a calcite gangue and are mainly free from pyrite, the blende being remarkably pure; in the Edwards belt serpentine is the principal gangue mineral; galena is subordinate to the blende and both to iron pyrite, while the blende is so heavily charged with iron as to be highly magnetic. In both Rossie and Macomb the gneiss is frequently seen to be in close contact with the limestone, yet no extension of zinc or lead along the contact-plane, even near the vein, is to be observed.

The large zinc deposits in the brecciated Knox dolomite at Mascot, and the Austinville zinc and lead mine in Virginia are types of zinc deposits where fissuring or strike-faulting is deduced from the surroundings rather than directly observed. The Mascot mine is on a line of brecciation at least 70 miles long. At Mascot the breccia is plainly a crushed bed or series of beds of dolomite. The assumption of faulting is based wholly on over-thrust faults a few miles distant, where the dolomites are seen resting on the Marysville limestone series. Although there are numerous places along the line of the Mascot breccia-zone where blende is observed, Mascot is the only spot where the veins have been proved to be economic. In other places, despite the extensive brecciation, absolutely no trace of lead and zinc is to be found. In Mascot a remarkably pure blende is the only mineral present in a gangue of bitter spar (dolomite). The bitter spar is the secondary filling of the interstices in the brecciated Knox dolomite, the fragments of which can be readily recognized. No blende penetrates these fragments, which, as a rule, are wholly unmodified. At Austinville, Virginia, the mine is indirectly recognized as a fissure. The host is here in places an impure dolomite banded in a striking way with thin ribbons of gray and blue. On the south of the mines the same ribbon-rock appears in contact with the pure dolomite. As the ribbon-rock at the river dips under the pure dolomite, both dipping at an angle of about  $45^{\circ}$ , the existence of a

fault is the obvious conclusion to explain the appearance of the ribbon-rock south of the mine. Aside from the probable main north-east fault with a throw of something like 3000 ft., there are numerous other faults which break the strata into great blocks. Along the fault-planes and many of the bedding-planes the rock has been brecciated and the interstices largely filled with lead and zinc sulphides. In parts of the mine iron pyrite occurs in great masses to the entire exclusion of lead and zinc. While not a perfect simile, the blocks of faulted and broken limestone seem to be wrapped about with a blanket of lead and zinc sulphides. The mineral solutions seem, in places, to have etched the bedding planes and the fault walls, but nowhere do they seem to have found their way into the mass of the dolomite blocks.

In the ribbon-rocks along New river, for more than a mile, lead and zinc sulphides occur in the moss of the rock in a manner to suggest crenulation of the strata, and the small amygdaloidal cavities thus formed are filled with ore. In the Austinville deposit no secondary metamorphic minerals are observed save occasional traces of fluorite.

The La Bufa deposit at Charcas, Mexico, structurally resembles the Austinville property in that, while the mine is evidently opened on a fault-fissure, the fault is inferred from contorted strata rather than from direct observation. In some ways it differs as radically from the Austinville mine as in other ways it closely resembles it. For example, the local metamorphism is intense, as manifested in the abundance of garnet, epidote, wollastonite, and hematite. In places the entire mass of rock is silicified, apparently with incipient wollastonite and garnet. There are many other examples which have come under my professional observation, but the above are types which are widely scattered from Salvador through Mexico and the United States, into British Columbia, and from the Rockies to the Appalachians. Out of the hundreds examined only twenty-two produce zinc ore on a very large scale, or are worked mainly for the zinc content. Of these, one each is in Salvador and Guatemala, six in Mexico, eleven in the Rocky Mountain region of the United States, and three in the Appalachian region, exclusive of the zinc mines in New Jersey.

From the above brief descriptions two significant facts stand out: First, that small, thin, sharp fissures, extensive both longitudinally and in depth, are characterized by unmodified walls, the vein content, consisting of nearly pure mineral, that is 90% or more; second, that in crushed zones in which the sulphides of lead and zinc occur in shoots of various dimensions from very low-grade ore, the mineralized gangue is mainly silicious, the shoots being pinched in places, and that where pinching occurs the zone continues with full width but then contains kaolinized feldspar in which is found the unchanged grains of the original quartz; and finally that wide intervals occur between the shoots, where the zone is filled with rotted rock having no trace of mineraliza-

tion. The two facts here cited appear to be of great value in passing judgment on a prospect. A thin vein, even with considerable swells on its exposed strike, will in all probability retain the same characteristics to whatever depth it is followed. In all probability there will be no crushed zone developed with depth, and unless the vein as exposed on the surface is rich enough to raise the stoping width to a profitable milling grade, the prospect will prove economically worthless. There are fundamental reasons for such a conclusion. In a sharp break the walls present a smooth plane of attack for the mineral solutions; the corrosive action must necessarily be slow and long-continued before the fracture can be sufficiently enlarged to permit of an economic volume of ore; the flow will be

ably in one form or another use the same criteria. For the inexperienced man it will be sufficient to state, as in the case of thin sharp-walled fissures, conditions exposed for a considerable distance along the strike will not be apt to change essentially in depth. Further, the conditions under which ore-shoots are formed should

NORTH-SOUTH SECTION, ALOTEPEQUE MINE, GUATEMALA

SECTION THROUGH BUFO MINE, CHARCAS, MEXICO

checked by the gradual filling of mineral or it will cease altogether. Again, in crushed zones the interspace between wall and wall will be filled with fragments and powder of the country rock. In passing judgment on a prospect of this nature three important possibilities will have to be considered: first, a general feeble flow of circulating waters, due to lack of high initial pressure, or, owing to the extremely fine comminution which may prevent circulation, however strong the initial pressure; second, capillary flow with a gradual enlargement of the channel, thus forming 'shoots'; third, coarse crushing in places affording open channels which may rapidly enlarge through solution of the finely comminuted rock, thus forming large and rich shoots, or the result may be interstitial mineralization between the large crushed fragments. To discuss in detail the foregoing phases would require too much space; besides, experienced examining engineers prob-

warn the inexperienced against the lure of 'extensions,' even with a rich mine on the adjoining claim. There are such extensions, of course, as seem to be the two contiguous claims in Butte, the Butte & Superior and the Elm Orlu. The Tonopah Extension is another instance. Examined in detail, however, it is more than probable that in both of the above instances the adjoining mines embrace the same shoot.

Contact deposits between sedimentaries is a subject that may be discussed briefly. 'Mantos,' or blankets of zinc ore, are common in the northern zinc-producing states in Mexico. In the San Matias district near Saltillo, one manto about one metre thick had been followed

SECTION THROUGH AUSTINVILLE ZINC MINE, VIRGINIA

down on a slope for about three hundred metres. On the south side of the mountain was a long wide zone of highly metamorphosed limestone with massive garnet abundantly developed. It is more than likely, though not proved, that the manto here was derived from an undeveloped, even unexplored, fissure less than one-half mile to the south. It can be readily understood that seepage, or even a considerable flow of mineral solutions, would follow between bedding planes, especially of lime-

stone, where the source would be in the crushed highly metamorphic fissure zone. As has already been mentioned, fault-spaces between large blocks of limestone in Austinville, Virginia, are heavily mineralized. In one tunnel of the mine successive limestone strata, wholly unchanged and unbroken, have zinc and lead sheets in bedding-planes, from one-half inch to three inches or more thick. It is probable that the bedding-plane mineral will enrich the barren limestone to milling grade. Between 500 and 700 ft. farther in the tunnel, the heavily mineralized fault-zones are developed. The derivation of the mantos from the fault-zones here seems to be self-evident.

Contacts between sedimentaries and eruptives and contacts between eruptives, to the tyro in mining, and even to the recently graduated mining engineer, are quite as alluring as 'true fissures'. Instances where mining engineers and mining geologists of experience and reputation have fallen victims to the 'contact' theory have often come under my observation. In one instance, over \$20,000 was spent in diamond-drilling to exploit the contact under the umbel of an assumed laccolith, in spite of the fact that miles of exposed sills showed unmineralized contacts between them, and their limestone hosts were at no great distance from the position of the drills. It is but fair to say that there is a decided difference of opinion on this subject among writers well qualified to pass judgment. One noted English geologist states unequivocally that "Whether or not an increase of temperature has been connected with the deposition of ore-veins, it is abundantly evident that the occurrence of igneous rocks has no connection with it." On the other hand, an equally well-known American authority on ore deposits, under the caption 'Deposits Related to Igneous Activity', states that\* "Several important groups of ore deposits must therefore be considered apart from the ordinary processes of metamorphism. This especially applies to those deposits of the rarer metals, which stand in the closest genetic connection with the eruption of igneous rocks."† My experience compels agreement with the first citation. At the Interstate-Callahan mine, a stringer of zinc-lead was followed for about one mile in the adit. At this distance a trap dike was cut and immediately on the other side of it the great vein was picked up. In Butte, Montana, aplite dikes frequently cut the copper veins. The copper content ceases at the contact but is picked up beyond. The Silver Pick vein in Mt. Wilson, Colorado, is a fissure in a fine-grained diabase. Though primarily the mine yields gold, were the vein larger it would have been an important zinc producer. Mining operations confirmed the surface operations. The diabase dike was intruded into a coarse granodiorite, probably monzonite. In the above two instances of contacts between older and younger igneous rocks, they evidently affected the mineralization not at all. In western Kentucky dikes accompany the faults.

In these faults fluorite is extensively deposited, and this mineral, in turn, is impregnated with sulphides of zinc and lead. The influence of the eruptives on the formation of fluorite and blende would seem to be negated by extensive faults in eastern Tennessee and in south-west Virginia, where zinc and lead occur accompanied by fluorite in small amounts, with one locality in which the fluorite constitutes about 50% of the gangue. In St. Lawrence county, New York, extensive fissures with galena and blende have some fluorite, but on intrusive igneous rocks, unless the black gneisses are conceded to be intrusive. Even so, however, these apparently could have had no influence since the lead-zinc fissures cut through limestone and gneiss in an unbroken line. In Guatemala a great zinc-lead series of deposits is frequently cut by dikes and by what are apparently sills, but only when the dikes and sills are fractured and these fractures filled with galena, blende, and, to a lesser degree, with chalcopryrite, are the intruded limestones mineralized with galena and blende. They then develop great masses of garnet, hornblende, and epidote. Practically the same phenomenon accompanies the zinc deposits in Charcas, San Luis Potosí, Mexico, and Hanover, New Mexico. Numerous similar instances could be cited.

Near Pembroke, Maine, small lenses and veins of blende occur in a fissured trap; in two places in New Hampshire lead and zinc are associated with igneous dikes, but, on the other hand, near Lincoln, in the same State, is a great crushed fault-zone in gneissoid rocks where not only does argentiferous galena occur with zinc-blende, but many of the rock-fragments have their feldspars converted to a greasy mineral, probably sericite, or else have them changed to epidote. No intrusive of any kind was observed. In the Triassic formation, between Northampton and Amherst, and also near Mount Tom, veins are found in the sandstone and are filled with barite accompanying a considerable amount of galena, blende, and chalcopryrite. No eruptives occur near the veins. Almost numberless citations of zinc and lead localities can be made but the summary would leave the question where it now is, balanced. The number of zinc and lead localities without accompanying eruptives would not be outweighed by those in which igneous rocks occur. The assumption of either fissures or eruptives as the primal cause of such deposits would be purely arbitrary. There are miles of barren fissures just as there are miles of barren contacts between eruptives and eruptives, and contacts between eruptives and sedimentaries. The factor common to both is an open channel or rocks prepared in such manner that channels can be opened in them. This leads to the brief consideration of another common factor, namely, rock disturbances, or rather preparation of the rock. It is as impossible to conceive of an igneous intrusion without disturbance as it is to conceive of a mineral deposit without such a forerunner. It is suggested that a fissure filled with an eruptive is as much a vein and even a fissure vein, as though it were a fissure filled with a gold, silver, lead, or zinc-bearing gangue.

\*Jukes, 'The Students' Manual of Geology', p. 372.

†Lindgren, 'Mineral Deposits', p. 73.

Even the existence of high temperatures, evidently a powerful factor in many mineral deposits as in many instances of rock metamorphism, may be no more inherent in eruptive rocks than in veins or in the metamorphism of rocks, but the temperature of all may have been derived from the same source, that is, the conversion of the enormous energy required to move and fracture huge rock-masses into nearly or quite corresponding heat equivalents.

In conclusion, I wish to disclaim the idea that this paper introduces any new factor into the consideration of zinc and lead deposits. What I do feel is that, in the honest zeal of investigation, some evident factors in the problem have been selected, to which undue value has been generally attached. Science is no doubt advanced by this method, for counter-checks are certain to follow, but these rarefied discussions are certain to be misinterpreted and misapplied in practical mining. The safe course for the practical miner is to bear in mind that no secondary mineral deposit can be formed without rock disturbance; that in spite of this, deposition of mineral rarely or never is co-extensive with the rock preparation. The fundamental principles governing zinc-ore deposits are fissuring or faulting, with consequent open channels for circulation of the mineral-bearing solutions. All other accompanying phenomena may be safely disregarded by the practical miner.

## Fused Bauxite for Furnaces

In a recent issue of 'La Cerambique,' M. N. Lecesne describes the following method of preparing bauxite for furnace lining and crucibles: A mixture is prepared of one part of anthracite and three parts of bauxite of an average composition of about 60% alumina, 10% iron sesqui-oxide, and 10% silica, moist as it comes from the quarry. The mass is charged into a furnace lined with refractory material, preferably fused bauxite, and previously heated with anthracite, air being blown through the charge at an initial pressure of about 40 in. water gauge, rising afterward, according to the depth of the charge, though 160-in. pressure is the usual maximum. The temperature rises quickly and the sudden vaporizing of the water in the bauxite causes it to break up and to granulate, while the aluminum carbide produced burns and raises the charge to a point at which the silica is volatilized, and the iron, reduced by the action, is expelled by the air-blast as a shower of sparks. The air-blast is continued in order to burn off the surplus anthracite and cool the fused mass, which can then be discharged from the furnace and ground, mixed with crude or calcined bauxite as a binder, molded, dried, and fired in the same way as calcined bauxite. If the fusion is performed quickly, say, in about three hours, the resulting mass will be highly porous, besides containing a sufficiency of unconsumed anthracite to facilitate grinding and briquetting. The fused bauxite will give a refractory material stated to be capable of withstanding a

temperature of over 2000°C. if mixed with some of the same material freed from iron by magnetic separation, and with water and quicklime, the latter forming a binder of silicate of lime. Mixed with bauxite the product is hard but porous, and forms a suitable lining for reverberatory or other furnaces heated with liquid or gaseous fuel.

## Uses of Stellite

The malleable alloys, as prepared by Elwood Haynes, are composed almost entirely of cobalt and chromium, though the proportion of the constituents may vary from 10 to 50% chromium, with a corresponding variation in the cobalt. These alloys are all hard, and while they may be scratched by the file, none of them is practically workable by this means. They cannot be machined, but some of the softest may be drilled by means of a hard-carbon steel drill or a drill composed of hard stellite. They resist nitric acid almost perfectly, even when boiling, particularly if the chromium content is over 15%. They forge with difficulty at temperatures ranging from 750° to 1200°C. They have been forged into tableware, such as spoons, forks, knives, and ladles, surgical instruments, pocket knives, dental instruments, evaporating dishes, crucible supports, lamp-stands, jewelry, including finger rings, cuff buttons, and scarfpins. These malleable alloys are all slowly attacked by either hydrochloric, sulphuric, or hydrofluoric acid, but are nearly immune to all chemical combinations, as well as the fruit acids. As the evaporating dishes made of this metal take a bright polish, and can be made with a comparatively light section, they will prove suitable for evaporating many chemical salts to dryness, and are particularly suitable for boiling the caustic alkalis. Substances may be evaporated to complete dryness in these vessels without any danger of breaking the vessel, since the tensile strength of the alloy exceeds 100,000 lb. per sq. in., and it also shows considerable elongation before rupture. When a vessel made of this material is struck by a hammer, it emits a clear musical tone, and continues to vibrate for a considerable length of time. The vessels retain their lustre in the chemical laboratory under practically all conditions, since they are not affected in the slightest degree by sulphuretted hydrogen, ammonium chloride, or other vapors. Furthermore, they are practically immune to acid vapors. They give excellent results in the form of lamp-stands, supporting-rings, triangles, and other laboratory apparatus. When these are heated to full redness, they become covered with a deep blue-black film, which does not change either in weight or appearance by repeated heating, and as no scale ever forms, these articles retain their weight, stability, and smooth surface indefinitely under all sorts of use. They can be subjected to temperatures up to 1200°C., and still retain a considerable amount of strength. In fact, the stellite alloys possess the highest 'red hardness' of any of the alloys yet discovered.

## War-Steel Production

\*Statistics have shown that the steel-ingot production in the United States in July was at the rate of 44,000,000 tons per year. An excellent authority compiled a statement last August revealing that the existing ingot-capacity was 49,500,000 tons, and that an additional 3,800,000 tons capacity was under contract, to be completed within six months. Finished rolled-steel production amounts to 76% of the ingot-production, hence the output for finished rolled steel was at the rate of 33,000,000 tons in July, at which season the production is generally about 5% below the year's average. Allowing for a considerable shortage of coke, even after the by-product ovens under construction are completed, we should be able to count upon 48,000,000 tons of ingots and 36,000,000 tons of finished rolled steel. The 11,500,000 tons of war-steel already included would be 32% of the output. The percentage is likely to be under rather than over 32%. If, under the stress of labor shortage, transportation difficulties, and other circumstances growing out of the War, the output should be restricted more than is here allowed for, there is good reason to believe that the commercial requirements in steel will be even more restricted, so that the essence of the argument is not affected, namely, that there is no serious danger of a decided shortage of commercial steel.

The distribution by the Government of orders on behalf of its Allies succeeds to such buying as these Allies have hitherto been doing on their own account. Last year's exports of steel under orders from the Allies amounted to about 5,200,000 tons. The steel consumed in making shells, machinery, and all other steel manufactures, has been estimated at about 1,800,000 tons, making a total of 7,000,000 tons of rolled steel for 1916 involved directly and indirectly in the export trade. The production was 30,500,000 tons, and thus 22,500,000 tons was left for the domestic trade. That is approximately the same amount as was consumed in 1912 and 1913, the best years before the War. Of the 7,000,000 tons involved in exports one may guess that something like 5,000,000 tons was included in exports to the countries now our Allies. The present war-steel programme absorbs the tonnage, whatever it was. There is every reason to expect that, as long as steel is scarce in the United States, the Government will not permit exportation to neutrals; hence, for the purpose of this argument, such exports may be neglected. The result is that, if we accept the figures of 11,500,000 tons of steel for the war programme in 1918, and the total production at 36,000,000 tons, there is left 24,500,000 tons for domestic commercial consumption, against 22,500,000 tons in 1916. It is difficult to see how this consumption could possibly increase, there being so many directions in which it is visibly decreasing. The greatest pinch will come to ship-plates. The production of mills that can roll such plates was only about 1,800,000 tons in 1916. The

largest figure yet set upon American shipbuilding in 1918 is that used by the British controller of shipping, who recently authorized the Associated Press to say that he would like to see 6,000,000 tons of shipping built in the United States in 1918. He set the amount of steel involved at 3,500,000 tons, which is a rather high proportion of the gross tons of steel to the gross register of the vessels. Deduction should be made for wooden ships in the programme of expansion for the merchant marine. There would be required, then, say 2,500,000 tons of ship-plates for our shipyards. This we can furnish, and some plates in addition for foreign yards, possibly 3,600,000 tons in all, or double our production of this class of plates last year, but certainly there will be no plates, except those not available for shipbuilding, for ordinary commercial purposes.

## Secondary Enrichment

The theory of ore enrichment may be briefly stated as follows, according to W. H. Emmons, who has prepared Bulletin 625 on this subject recently issued by the U. S. Geological Survey: Mineral deposits that are exposed to weathering, that is, to the action of the atmosphere, of rain, frost, and other agencies, break down and form soluble salts and new minerals that remain unchanged under surface conditions. In the course of weathering, however, the ore of each metal behaves in its peculiar way. Deposits of iron, aluminum, manganese, and some deposits of gold and other metals may be enriched near the surface by the removal of valueless material. On the other hand many of the valuable metals, including copper, silver, and less commonly gold, zinc, and lead, go into solution and are carried downward by rain water and re-deposited, and thus parts of the orebodies may be enriched. Most of the rich or 'bonanza' orebodies of copper, many of silver, and some of gold and other metals, have been formed in this way. Bulletin 625 describes in detail the geologic conditions favorable and unfavorable to the formation of enriched mineral deposits and gives a summary of the criteria by which such deposits may be recognized. The natural chemical processes by which enrichment is produced are fully described and the behavior of each metal is considered separately and is illustrated by descriptions of practically all the known valuable enriched orebodies.

CORUNDUM mining has been revived at Corundum Hill, North Carolina, by the Hampden Corundum Wheel Co. of Springfield, Massachusetts. Emery is also being produced in Westchester county, New York, the quantity shipped amounting to 15,282 tons. The excessive use of abrasives on account of the increase in steel manufactures during the War has again brought these natural products into demand. For years the artificial abrasive, carborundum, has kept natural corundum out of the market, being more cheaply produced. Electric power at Niagara, however, is now more usefully employed in other manufactures not otherwise obtainable.

## Chrome Deposits of Alaska

By W. P. LASS

The deposits of chrome ore in Alaska have, until recently, been rather overlooked by the industrial companies of our country and it was not until the rise in the price of chromite that local operators have undertaken to market the ore. The more important known deposits are on the extreme far point of Kenai peninsula, while the zones of mineralization may be traced eight to ten miles inland. Although no systematic prospecting has been done to any great distance from the edge of salt-water, there are nevertheless several areas where important deposits of chromite have been explored. Notable among these are the deposits at Red mountain, described in the U. S. Geological Survey Bulletin 587.

I was called upon to examine these deposits in the fall of 1916, and although shown several exposures containing from a few hundred to a thousand tons of high-grade

freighters to Seattle, but the greater part of the shipments were lightered direct from the beach to steamers anchored about 300 yd. off shore. The present freight rate on 100-ton shipments to Seattle is \$3.50 per ton. From Seattle to Atlantic Coast points the railroad rate is \$12 per ton. As this material is essentially a war-product, no difficulty has arisen in obtaining cars, and satisfactory deliveries to Eastern points have accordingly been made.

## Calcination of Magnesite

Operations have been begun at the reduction plant of the Piedra Magnesite Co. at Piedra, Fresno county, 30 miles east of Fresno, California. The equipment has a total capacity of about 60 tons of calcined ore or twice that amount of crude ore per day.

The plant and its equipment represents an investment of \$55,000. Thomas J. Curran, manager for the American Magnesite Co. of Porterville, is general manager for

CHROME MINING ON THE KENAI PENINSULA, ALASKA

ore, they were not deemed worthy of development by local capitalists who, in turn, had to depend upon selling their ore in a very unstable market. Should the present demand for chrome ores continue, however, throughout the coming year a more thorough prospecting and development of this belt will take place.

Although the conditions for marketing have not justified large expenditure in this region, there are deposits, nevertheless, so close to salt-water as to make the shipment of this ore well worth while. The accompanying photograph shows workmen removing the top, quarry fashion, from a high-grade deposit of chromite. Approximately 1000 tons of ore, containing from 46 to 49% chromium oxide, was removed from this deposit during the past summer. No development work was done to determine the extent of the deposit, and there remains approximately 1000 tons of ore in sight above the line of high tide. The ore between high and low tide is 18 to 20 ft. wide and contains from 48 to 52% chromium oxide. No development plans for the working of this deposit below the line of high tide have been made. Some shipments of this ore were made by barges to the docks at Port Graham and Seldovia and thence by

the Piedra Magnesite Co., W. B. Phillips of Porterville is superintendent, and J. W. Thomas treasurer.

The rotary kiln at the plant is 83 ft. long and 8 ft. diameter and weighs 80 tons. The cooling-tower is 60 ft. high. The red-hot ore is carried to the cooling-tower from the kiln by a 125-ft. chain-bucket elevator. The ore is fed into a gyratory crusher from which it is lifted to a large revolving screen where the fine ore is screened and sent through a chute to the ore-bin, which has a capacity of 75 tons, and from which the ore is fed through a dust-chamber into the kiln. The ore that fails to pass through the screen is returned to the crusher. All ore passing into the kiln is reduced to pea-size and is calcined quickly. The machinery about the plant is operated by electricity.

The Piedra Magnesite Co. owns eleven different mining claims, but at present is working only seven or eight of them. The reduction plant, which is on the banks of Kings river, is about half a mile from the quarry. The ore is hauled to the plant on motor trucks. About 125 men are employed at the plant and quarries. All the ore of the company has been contracted for by the American Refractories Co. of Pittsburgh, Pennsylvania.

## Gold Output of Colorado

These statistics of the U. S. Geological Survey are interesting; they prove that the Leadville district, in Lake county, is still a dominant factor in the mining industry of Colorado, the silver-lead production of the early days

than 2%. On the other hand, they all contain a variety of other metals, more especially copper, tin, nickel, and lead.

The importance of magnesium as a de-oxidizer must not be overlooked, for it is even more readily oxidized than aluminum; and its beneficial influence on aluminum is in no small degree due to its power of freeing that metal from dissolved oxide.

The three magnalium alloys most commonly used in this country [England] are described by the makers as *X*, *Y*, *Z*. Of these, *X* is intended solely for castings where strength is of primary importance; *Y* is used for ordinary castings; and *Z* is intended for rolling and drawing.

As regards alloy *X* it has been stated by Barnett that it contains 1.76% copper, 1.16% nickel, 1.60% magnesium, and small quantities of antimony and iron.

Alloy *Y* is somewhat similar in composition, except that it contains no nickel, but small quantities of tin and lead.

Alloy *Z* contains 3.15% tin, 0.12% copper, 0.72% lead, and 1.58% magnesium.

The tensile strength of ordinary castings with alloy *Y* varies from 8½ to 10 tons per square inch, and that of rolled samples of alloy *Z* varies from 14 to 21 tons per square inch.

The alloys work well, and excellent screw-threads can be cut. The speed of working is about the same as that of brass, and the tools should be lubricated with turpentine, vaseline, or petroleum. Alloy *Z* is exceedingly ductile, and can be spun and drawn into the finest wires. For these operations vaseline or a mixture of 1 part stearine and 4 parts turpentine has been found suitable. In drawing tubes or wire the alloy must be annealed by heating and cooling suddenly. Slow cooling produces hardening. Magnalium is very little affected by dilute acids and can be employed with perfect safety for the manufacture of cooking utensils and all culinary appliances.

OIL may be more economically burned, according to W. A. Janssen, by pre-heating the air, then mixing it in definite proportions with the oil, creating a combustible gas which is forced into the furnace under positive pressure. This results in perfect combustion since exact regulation of the air is possible.

### PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC AT MINES IN COLORADO IN 1916

[Compiled by Charles W. Henderson.]

County.	Pro- ducing mines.	Ore sold or treated (short tons).	Gold.	Silver (fine ounces).	Copper (pounds).	Lead (pounds).	Zinc (pounds).	Total value.

Summit.....	55	65,117	673,891	120,207	14,581	1,688,637	13,940,948	2,741,177
Teller.....	64	945,820	12,119,550	79,804				12,172,061
Total, 1916.....	852	2,697,243	19,153,821	7,656,544	8,624,081	70,914,087	134,285,463	49,200,675
Total, 1915.....	821	2,737,020	22,414,944	7,027,972	7,112,537	68,810,587	104,594,994	43,426,697
Increase or decrease.....	+31	-39,777	-3,261,123	+628,572	+1,511,544	+2,103,490	+29,690,469	+5,773,978

The average prices for metals for the calendar years 1915 and 1916 were:

	1915.	1916.
Silver, per fine ounce, at New York.....	\$0.507	\$0.658
Copper, per pound, electrolytic, at New York.....	.175	.246
Lead, per pound, at New York.....	.047	.069
Zinc (spelter), per pound.....	.124	.134

The average price used for spelter is not the market price at St. Louis, but the average selling price of zinc as shown by canvass covering all sales.

being supplemented now by an important output of gold and of zinc. Cripple Creek places Teller county far in the lead of the gold-producing districts. Next comes San Miguel, which includes the Telluride district. Creede is identified with Mineral county and Aspen with Pitkin county; both show a great decline from the early prosperity. The old mining centres of Clear Creek, Gilpin, and Ouray are still pegging away bravely. It will be noted that the grand total is \$5,773,978 higher than in 1915.

## Magnalium

Reference was made recently in our editorial columns to this remarkable alloy, used in the making of aeroplanes. We find that Frank L. Hess, in his report on 'Magnesium in 1915,' published by the U. S. Geological Survey, quotes a description of E. F. Law, an English authority:

Commercial magnalium contains only a small percentage of magnesium, and, although a large number of alloys are manufactured and sold under the name of magnalium, few of these, if any, appear to contain more

# REVIEW OF MINING

## MAMMOTH, UTAH

RARE-METAL ORES.—TINTIC STANDARD.—DRAGON.—IRON BLOSSOM.

According to Magnus Benson, an old Nevada-Utah prospector, some rare ores have been found in western Boxelder county. The ores are those of molybdenum and tungsten. Mr. Benson and his associates have taken up the Blue-Bell group of seven claims located 16 miles north-west of Terrace station. This is in the extreme north-western corner of the State, near the Nevada-Idaho line. The formation there is mainly a shattered granite with the ores occurring in prominent fissures. One of the principle fissures in the Blue-Bell group shows on the surface for over 4000 ft. This fissure is from three to four feet wide where opened on the surface and is quartz-filled. The rich ore occurs in pockets and is easily sorted. A shaft will be sunk on the fissure; there are also good tunnel-sites. The owners expect to ship a carload of this rare ore from Terrace at an early date. Associated with Mr. Benson are George W. Parsons and J. A. Lynch. At Bovine, six miles distant, tungsten ore is being mined for shipment this fall. Ogden people are making preparations to start development soon. While the embargo on the ores at the mines to the A. S. & R. Co. has been extended from October 1 to October 15, it was stated yesterday by a mining official that the embargo had been lifted for a period of five days, beginning this week. This will give the mines that have been holding back for three weeks an opportunity to rush in considerable of their accumulated stock. There has been no embargo at the plant of the U. S. Smelting company for more than three weeks.—Directors of the Uncle Sam Con. M. Co. met on Monday and levied assessment No. 2, consisting of 1c. per share. The delinquent date is November 9 and sale date December 10. Fred C. Dern is secretary.—Directors of the Tintic Standard Mining Co. met on October 9 and declared the second dividend of 2c. per share, which means a payment of nearly \$24,000. The distribution will be made on October 25 to stock on record October 20. The initial dividend of \$24,000 was paid on June 27. This makes a total to date of \$48,000 on the 1,200,000 shares issued. E. J. Raddatz, the general manager, said that the company made a payment of \$12,000 in cash on some of the newly-acquired property. During the past two weeks the mine has shipped 11 carloads of ore, or about 550 tons. The connection between the new shaft and old workings will be made shortly, only 20 ft. of ground intervening, and a raise of 23 ft. This will make connections at a point from the old 1200-ft. level by incline to the 1650-ft. level, which is 1250 ft. vertically. The drift from the new shaft is on the 1260-ft. level. This has passed out of the shipping ore now and is making for the point of connection.—The director of the Dragon Con. at the regular monthly meeting at Provo on October 14 declared the usual quarterly dividend of 1c. per share, payable on October 25 to stock on record October 15. This is the fourth dividend and brings the total distributed to \$75,000. The first dividend was paid on January of this year. The Tintic record of shipments of ore shows that the Dragon leads all other mines of the district by a big margin. A comparatively small amount of higher-grade ore was marketed at the same time, so the car-lots run high. The September total for Dragon amounted to 184 carloads: August,

254, July 145. The total for the first six months of this year was 876 carloads.—An assessment of half a cent was levied by the Tintic directors at Provo on October 14. This became delinquent November 15. Sale day is December 8. It is stated that the object of the levy is to liquidate the company's share of the drift from the 1700-ft. level of the Iron Blossom. This drift is now about 140 ft. inside of Central territory. Boston officials give out the information that the Utah Metal & Tunnel Co. has made a contract with the International Smelting Co. whereby the latter will purchase all the company's product for a period of five years. The price will be the average price for the week preceding the receipt of the ore. The company's engineers estimate that there is sufficient milling ore developed for more than three years' supply, and the low-grade ore is increasing so rapidly that the mill capacity must be still further enlarged or a new mill built at the other end of the tunnel in the middle canyon. The new additions to the mill at Bingham were completed October 1, and will go into operation immediately; this increases the capacity of the mill by 50%, making it 400 to 450 tons per day.—Directors of the Iron Blossom Mining Co. at Provo have declared the regular quarterly dividend of 5c. per share, payable on October 25 to stock on record October 15. This will bring the 1917 dividend up to \$250,000, or 25c. per share. The stock sold down to 66c. after this dividend announcement. This distribution will bring the total Iron Blossom dividends up to \$3,100,000 or at the rate of \$3.10 per share. Last year the company distributed 35c. per share, or \$350,000; 33c., or \$330,000, in 1914; and 40c., or \$400,000, in 1913.—Iron Blossom shipped 75 carloads of ore in September, 85 in August, 82 in July, and 761 during the first half of this year. While it is admitted by officials that the recent extensive prospecting on deep levels in various parts of the mine have been disappointing, it is felt that at any time new orebodies may be discovered, as Iron Blossom still has a large unprospected territory. During the first nine months of 1917, the Utah mines have paid dividends aggregating \$22,252,680, compared with \$24,529,430 last year. The total dividends paid by these 21 mines amount to the gigantic aggregate sum of \$120,314,060.—Theodore P. Holt, superintendent for the Tintic Milling Co., at Silver City, is expected back from Canada during the coming week. Mr. Holt went to Cobalt some months ago for the purpose of building some of the new Holt-Dern roasters. The Holt-Dern roaster, first used at a mill at Park City and then at the Tintic mill, is an invention of Mr. Holt and George H. Dern of Salt Lake City.—Shipments of first-class ore from the mines of Tintic this week totaled 172 cars, estimated at 8000 tons, and valued at \$200,000. Dragon Con. continues to head the list, with Iron Blossom and Chief Con. running neck and neck for second place. Ore was shipped from 19 mines.—Cecil Fitch, superintendent of the Chief Con. mine, states that actual mining operations will soon be in progress through the shaft of the Plutus company. The Plutus is controlled by the Chief. The officials of the Chief have decided that the old Plutus shaft could be used to advantage in the development of the large tract of mineral ground which the latter company owns, and consequently the work of putting this shaft in shape was started. The shaft, down to a depth of 400 ft., had to be repaired from top to bottom and new hoisting machinery put in.

All of this work has been completed and shafts and drifts on the 400-ft. level are being unwatered. There is no big flow of water at that depth, but during the many years that the property has been idle the water has accumulated.—A new hoist, secured from the May Day company, is being moved to the Eureka Bullion company in the east end of this district. The latter company's shaft has reached a depth of 545 ft. and better hoisting equipment is necessary to continue the sinking operations. The hoist which has been secured will be good for 1000 ft. or more, according to John Bestlemyer, the superintendent. Manganese is now coming in at the bottom of the Eureka Bullion shaft, and the indications are said to be more favorable than at any time since work started.—The Mammoth mine dividends for 1917 amount to \$360,000, all of which has been paid out since May 1. The last distribution of \$40,000, or 10c. per share, will be paid on October 12.

Thomas L. McCarthy, M. E. Price, and F. E. Butler, of Salt Lake City, have taken a lease on the manganese claims of the Chief Con. Mining Co. at Homansville, and the Eliener, Cromar, Nelson, and Morgan, in the Erickson district, and work has been started. The ore which is now being mined carries about 35% of manganese. The drift at the Zuma is still following the stringer of lead-silver ore, cut some weeks ago. Since the work was stopped in the main drift and the cross-cut, driven along the fissure, the ore has been followed a distance of over 100 ft., the value remaining fairly constant.—The Chief Con. has purchased \$100,000 worth of Liberty Bonds; this company took \$50,000 worth of the first issue.—Sinking has been started at the North Beck mine next to the Eureka mines. An electric hoist and air-compressor have been added to the equipment.—The Utah Zinc Mining & Milling Co., B. F. Fleiner, superintendent, has uncovered some high-grade lead-silver ore at several points on its property; about 150 tons of lead ore, carrying 35 to 40%, is ready for shipment.—After the sinking of a winze to 100 ft. below the adit, driving is now in progress at the O. K. Silver property, near Indian Springs. The mine is controlled by the Kearns and Keith interests of Salt Lake; some two years ago it produced some high-grade silver-lead ore.—Two carloads of bullion will be shipped from the Tintic Milling Co.'s plant at Silver City before November 1, according to George H. Dern, the manager; the plant is now shipping at the rate of more than a carload of bullion every month. The ore being treated is mainly from the Dragon Consolidated, Iron Blossom, and Colorado; a small quantity comes from other neighboring Tintic mines. The mill is treating 200 tons per day. The mill-product is shipped to the refineries at Newark, New Jersey; it contains 90% copper and from 600 to 2000 oz. in silver.

## SUTTER CREEK, CALIFORNIA

OLD EUREKA.—HARDENBURG.

The Alpha Lode mining claim, sometimes called the West Eureka property, has been acquired recently by the Old Eureka Mining Co., which purchased it from William J. McGee. This strip of ground adjoins the Old Eureka on the west and was first worked in the early 'seventies by D. D. Reaves and associates. McGee's title to it was acquired through foreclosure-proceedings. The ground is considered to be valuable, particularly to the Old Eureka Co. It has been opened by shallow shafts and an adit, and sufficient work has been done to demonstrate its worth. It will doubtless be worked in conjunction with the Old Eureka mine, as some of the Old Eureka orebodies crop there. In addition to the property purchased from Hetty Green, and last worked about thirty years ago by Alvinza Hayward and others, the company has purchased two large ranches to the east for a mill-site and tailing-dump. The principal stockholders are said to be the new owners of the Wildman, Mahoney, and Lincoln properties, which group ad-

joins the old mine on the north. The bottom of Old Eureka shaft is being enlarged to provide for three compartments.—Failure to find enough ore to justify further expenditure is the reason the W. J. Loring company has discontinued operations under its option at the Hardenburg mine, south of Jackson. The property reverts to the former owners, who are the same men interested in the South Eureka property at Sutter Creek. The rich find reported in the Hardenburg mine recently proved to be only a small pocket. Large low-grade orebodies are in sight, but the cost of handling them under present conditions is prohibitive.—Conditions at the Central Eureka mine are improving. The value of the mill-heads shows an increase and there is prospect of the present 3c. assessment putting the property in a workable condition.

## HOUGHTON, MICHIGAN

A RETROSPECT.—OSCEOLA CON.—MOHAWK.—CALUMET & HECLA. COPPER RANGE CO.—SOUTH LAKE.

The production of copper for October from the Lake Superior district will exceed that of September by at least 2,000,000 lb. if the present rate of production is maintained. The decided falling off in production in September occasioned considerable surprise and a good deal of comment from shareholders. In comparison with the copper production in other mining districts in the United States the showing was exceptionally good, and, in this connection, it must be remembered that the slump in output is not entirely due to shortage of labor but to a more important factor. A few months after the War started the price of copper began to advance. Just at the outbreak of the War it was low, sales being made at 10c., and there was a considerable accumulation of metal on hand. The wiser buyers for the Allies and the wiser domestic consumers immediately began to buy heavily at the low price. Then the buyers for the Allies all jumped into the market, and the price began to advance sensationally. There was a brief respite when foreign war requirements were all placed in one hand for purchasing, but the price continued at an abnormal figure. Confronted with the certainty of 'fat' profits, mine managers in the Lake Superior district were faced with two problems. One was constantly increasing costs; the other was whether it was desirable to mine the richest ore in their property, making all the possible profit, and take every advantage of the high price, or to mine just average ore, maintain advance openings to the limit of expectations, and even to send to the mill considerable ore that would show a profit with copper at 25c. but could not be mined with the metal at 11c. There are plenty of arguments on both sides of the question. A few of the mines in this district began mining copper that ran 50 lb. per ton and made wonderful profit. In fact they figured that never again would the opportunity present itself to get such a result from a copper mine. And the surprising thing about it was the way results kept up. Month after month the looked-for slump did not come; now that it has, there is surprise and dismay. Yet the result is but the natural outcome of the policy which has plenty of justification in profits accrued and in dividends paid. But most of the 50-lb. copper has been cleaned up, and even if tonnage is maintained, a lower percentage of copper is all that can be expected unless some richer stopes are opened in newly-developed territory. The reduction in output of two or three Lake Superior properties, due to the fact that the 'fat' places are cleaned up, is going to count as a considerable factor in the reduction of copper output from this district in 1917.

Directors probably will not accept the resignation of John C. Greenway, manager for Calumet & Arizona, who is now a Major of Engineers in the United States Army, but will grant him leave of absence during the War and select one of the directors, either Mr. Campbell, the Secretary, or E. C. Cong-

don to act as managing director during his absence.—The reduction of the Osceola Consolidated dividend to \$2 per quarter is based on the preparation for the super-tax, for reduced profits owing to the lower price of copper, and a desire to conserve a treasury-surplus until the metal situation becomes settled. There is a great shortage of trammers at No. 4 North Kearsarge.—Notwithstanding the high cost of construction work, all of the mines here are repairing the residences of employees and erecting new ones; Champion is to erect 25 new homes for miners; Trimountain 15. At the Quincy stamp-mill new dwellings are being built and the old ones improved.

There is a slight improvement in the small amount of opening work being done in Mohawk No. 1 shaft. Last year there was no betterment and the mineralization was considerably below the average of the mine. For the purpose of exploring the formation to the east and west of the Mohawk lode, cross-cuts were driven on the 21st level at a point 670 ft. south of No. 2 shaft. The cross-cut west, or in the hanging, has now reached a distance of 740 ft. and the cross-cut east 654 ft. Several amygdaloids were intersected, none of which shows sufficient encouragement for further work. The Wolverine sandstone was found in the east cross-cut 350 ft. from the foot-wall of the Mohawk lode.—The 17th and 18th levels south of No. 3 shaft at the Ahmeek have been extended to the Mohawk boundary; all are in fair ore. Last year the five levels just above were all extended to this same boundary line. The shaft is down close to the 22nd level. The Fulton fissure crossed this shaft at the 17th level.—One third of the production of copper which the Calumet & Hecla secures from the three shafts it operates on the Osceola lode, at the old mine, comes from the foot-wall stopes. This lode, particularly in the Calumet & Hecla property, has peculiar difficulties. It is utterly impossible to mine across from foot to hanging wall because the lode varies in width from 10 to 160 ft. The copper content is so lean, running little better than 13 lb. per ton, that there is but one practical method of handling it, namely by following the copper course as carefully as possible. For this reason operations in shafts 13, 14, and 15 require miners of unusual ability and shift-bosses who use discretion in avoiding poor ore.

Annual report of mines inspector of Houghton county for year ended October 1 showed total number of underground men to be 16,423. This compares with 16,250 in 1916, 16,005 in 1915, and 12,954 in 1914. It will be seen, then, that, with all the hue and cry of shortage of men and the fact that every mine needs more men underground, the working-figure is better than the average. The percentage of casualties was 0.0029. Of the 48 men killed in the mines, Champion lost seven and Calumet six.

At the present rate, production at Mass Con. ought to run to 19,000 tons of ore in October. The Evergreen lode is furnishing some ore, but Butler continues to be the largest producer. Recent openings are encouraging.—The No. 4 North Kearsarge of Osceola Con. is getting into the best grade of ore found anywhere in the mine. The ore tonnage at old Osceola branch is maintained, but the total for October will not be much over 100,000 tons.—North Ahmeek now furnishes 40% of the Ahmeek total which is likely to be 110,000 tons this month.—The ore coming from South Lake shows an average of 17 lb. per ton, all of which goes to Winona mill.—The Copper Range railway plans to take over haulage for Wolverine and Mohawk in two months. Ore production at Wolverine is down to 34 cars per day.—Mohawk may reach an output of 50,000 tons in October. The copper content averages 19 lb. per ton.—Long drifts at the La Salle toward old Osceola show good copper. The output is close to 15,000 tons per month.—The Centennial September output was 10,000 tons. The difficulty of securing men for this mine and long tram hauls makes the cost high.—Repairs to the old shaft-hoist at the Franklin are completed, and hoisting is now at the regular speed. The output for September was 23,000 tons

compared with 27,000 in August. The old shaft has a full crew, but more men could be worked at No. 2.—Allouez is one of the few Lake Superior copper mines that will show a substantial increase in output for 1917.—No new ground is being opened at Superior and the tonnage is declining steadily. The Houghton Copper, next adjoining, confines operations to exploring from Superior's openings.

The three mines of the Copper Range Co. continue to produce copper at pretty close to normal rates, the daily tonnage running 3600. In September the three mines sent to the mills over 100,000 tons of ore, averaging 30 lb. per ton. This tonnage is slightly under the average of the properties covering a period of ten years. During 1916 the three mines combined took out 1,187,119 tons of ore. The Champion mine continues to be the richest and largest producer, turning out more ore and more copper than the Trimountain and Baltic combined. In fact the Champion produced last month more than 60,000 tons of ore and the Baltic 26,000 tons, while the Trimountain turned out only 16,000 tons.—South Lake produced 3500 tons of ore last month, which was rich in copper. The ore was crushed at the Franklin mill at Point Mills. Beginning with October 1, however, the South Lake ore will be crushed at the Winona mill. This arrangement saves railway haulage. The September output is 1500 tons under that of August.—Surprising though it may seem, Adventure is getting out more copper ore than Lake, the tonnage in September being 6000, compared to 5500 for Lake.—Arrangements have been completed whereby R. R. Seiber, who has been superintendent of Winona for a number of years, will hereafter operate the property on tribute, guaranteeing profits to the company.

Foundations for the machinery for a power-house at the Seneca have been laid. It is hoped that the shaft-house will be enclosed before the winter, so that sinking can start before the new year.

## TONOPAH, NEVADA

TONOPAH EXTENSION.—TONOPAH BELMONT.—WEST END CON.—  
JIM BUTLER.

During the month of September the Tonopah Mining Co. milled 9800 tons of ore averaging \$12.70, from which a net profit of \$35,060 was obtained. During the previous week 2600 tons of ore averaging \$10.13 was milled.—In the Silver Top 130 ft. of development was done, 85 ft. in the Sandgrass, and 7 ft. in the Mizpah. Last week the production was 2350 tons.—The Tonopah Extension Mining Co. has opened up the vein on the 1680-ft. level of the Victor; it averages 5 ft. of good ore. In the Victor 115 ft. of development has been done and 76 ft. at the No. 2 shaft. At the latter, on the 1260-ft. level, stoping continues on the Murray vein on a 6-ft. face and on a 5-ft. face on the O. K. vein. The Victor raise 631 shows a 5-ft. face of ore. On the 1540-ft. level, 1515 east drift cut a 2-ft. vein, and the 1503 raise continues on a 3-ft. face of ore. The production for the past week was 2380 tons.—The Tonopah Belmont Development Co. milled 10,160 tons of ore during September, making a net profit of \$102,742. On the 1000-ft. level, raise 72 on the Rescue vein shows an increase in the width of the vein and also an increase in value. On the 1166-ft. level, west drift 21 on the Mizpah Fault vein shows a 3-ft. face of fair ore. Branch B of the Mizpah Fault vein, cut last week, shows a 2-ft. face of fair ore. Last week's production was 2429 tons.—The fine showing of high-grade ore in the Ohio vein of the West End Consolidated Mining Co. continues. The ore exposed in the 512 and the 555 cross-cut No. 1 proves the vein for nearly 700 ft. on its dip to the east and 500 ft. along its strike, north and south. As the vein has been exposed within 50 ft. of the MacNamara company's end line, there is a possibility of the Ohio vein being found there. Raises 528 and 529 have both reached the hanging wall of the vein, exposing

7 ft. of fair-grade ore. Drift 531 to the south continues to open up the high-grade orebody. Drift 530 is being run north to prove that area. Drift 717 No. 2 at the West End shaft has been resumed for connection on the west side, and 717 cross-cut No. 3 has been discontinued. The mill clean-up for the first half of October consisted of 31 bars of bullion, valued at \$49,458. The output the last week was 1063 tons. At the Halifax Tonopah Mining Co. 1256 cross-cut intersected a vein of quartz carrying gold.—The Jim Butler Tonopah Mining Co. during the month of September milled 3467 tons of ore, resulting in a net profit of \$55,000. On the 200-ft. level raise 367 on the Wandering Boy vein shows a 2-ft. face of good ore. Between the 300 and 400-ft. level the north cross-cut intersected the Wandering Boy vein exposing  $1\frac{1}{2}$  ft. of low-grade quartz. Raise 6 on the 700-ft. level cut the hanging-wall branch of the West End vein. It shows 18 in. of fair-grade ore. The production for the past week was 500 tons.—At the MacNamara Mining Co. stoping on the 200-ft. level shows some excellent ore, while the other stopes show fair-grade ore. The production the past week was 315 tons.—Last week the Rescue-Eula produced 132 tons, the Montana 116 tons, and the North Star 56 tons, making the week's production at Tonopah 9341 tons with a gross value of \$163,467.

### COBALT, ONTARIO

BEAVER CONSOLIDATED.—HOLLINGER CONSOLIDATED.—MCINTYRE-PORCUPINE.

An aggregate of 16 cars of ore in a single week was the new high record set by the Mining Corporation during the second week of the current month. The approximate weight of the ore was a little more than 500 tons. Not only at the Mining Corporation, but at every other producing mine in the camp the fixed policy appears to be to maintain production at the highest possible point. Results of operations below the diabase sill at the 1600-ft. level at the Beaver Consolidated are encouraging. This is the deepest working at Cobalt and will have a material bearing on the future of a number of neighboring properties. In order to get below the sill, a shaft had to be sunk through approximately 1000 ft. of barren diabase. Early in the year a vein containing considerable high-grade ore was found. Stoping operations, however, have been disappointing, the grade of the ore not holding as good as that first found. This week a winze has been started on the high-grade ore-shoot, and the development of the next few months will be watched with critical interest.—The Cobalt Silver Bird has been re-opened recently. The property has been classed as a wild-cat and has never received a thorough test. However, it is now in the hands of the O'Brien mine and will be thoroughly explored.—The production at the Kerr Lake is being maintained at around 7000 oz. of silver per day. Working over unusually wide stopes the tonnage also is well maintained.—From the Nipissing mine the production is understood to approximate \$10,000 per day. Practically all ore-shoots are extending beyond their previously known limits and the ore-reserve at the end of the year is expected to compare favorably with that of the preceding year.

The number of mine-workers in the Porcupine field is increasing. The increase appears to be the result of the high rate of wages being paid and the release of workers from harvesting and threshing in the West. The Hollinger Consolidated and the McIntyre-Porcupine are both in a favorable position, and the rate of production is increasing. Development at the 200-ft. level on the Miller-Middleton side of the Hollinger is understood to be greatly exceeding expectations, and, in fact, has constituted one of the big surprises of the year. Though the wide body of ore on surface was low grade, it has been found at the 200-ft. level to be above the average in the mine.—The development campaign at the Porcupine

Crown is being continued with favorable results, energy being directed largely to this one branch of the work. Were the working forces to increase materially, the Porcupine Crown would at once re-commence milling operations at full capacity. In the meantime, however, production is being maintained at a rate sufficient to cover expenses, and development work is going ahead at a record rate.

The Porcupine V. N. T. orebody at the 600-ft. level is approximately 20 ft. wide and has an average gold content of over \$11. Driving operations are under way and the ore-reserves of the mine are increasing.

### TAMPICO, MEXICO

DEVELOPMENT OF THE OILFIELD.

Oil is the magnet that is attracting large sums of American and British money to Mexico. Although foreign investments have already wrought a wonderful transformation in the physical aspect of the Gulf coast to the south and west of Tampico, this improvement has only begun, judging from present indications. The influence of the remarkable industrial development that is in progress in Tampico and the coast oilfields is having its beneficial effect upon every class of citizens. An enormous amount of industrial improvement is under way and in contemplation at Tampico and adjacent oil-producing territory. According to reliable estimates, approximately \$60,000,000 gold will be expended in the near future in the construction of new refineries, oil-pipe lines, wharves, storage-tanks, and pumping-plants. It is stated that plans have been prepared for the immediate construction of twelve new refineries here. The plant of the Aguila Oil Co., which is owned by Lord Cowdray of London, England, and associates, will, it is said, be among the largest in the world. Practically all the large oil-producing and refining companies in the United States and many in Europe have extensive holdings in the Tampico district and are preparing to build refineries either at Tampico or in its immediate vicinity. Although the oil of the different fields in this territory is of a heavy grade, modern refining methods are capable of obtaining from it good yields of gasoline, leaving the unrefined portion available for fuel. According to recent estimates, the wells now completed, nearly all of which are capped, are capable of a total production of about 10,000,000 barrels per day. This available output is more than forty times the quantity that is now being used. Construction has already been started on several new pipe-lines, pumping-plants, and storage-tanks, and material for new refineries is being received by every boat from the United States.—The well of the Mexican Petroleum Co. at Cerro Azul is keeping up its regular flow of 15,000 bbl. through the pipe-line to Tampico. Although this well has been flowing for several years and has given a total output of more than 57,000,000 bbl., it showed by a recent test when the throttle was taken off that it still has a daily capacity of 257,000 bbl.—The Mexican Petroleum Co., E. H. Doheny of Los Angeles, president, has several producing wells in the Tampico district that are almost as large as the one at Cerro Azul. The British government is not taking any chances on the oil-wells of Lord Cowdray and associates being destroyed, in order that the supply of fuel-oil from that source for the British navy may be cut off. The exportations for the British navy by the Cowdray syndicate are all delivered by means of ocean-loading pipe-lines placed some distance out from the mouth of the Tuxpam river, near the port of Tuxpam, about 120 miles south of Tampico. The source of this oil-supply is from fields adjacent to Tuxpam. In order to be protected in case of any possible emergency, the British government entered into a contract with the Mexican Petroleum Co. whereby the latter is required to keep 40,000,000 bbl. of oil in storage at Tampico. At a cost of more than \$2,000,000 the Mexican Petroleum Co. constructed the necessary steel tanks to take care of this enormous quan-

tity of oil. Some idea of the oil-resources of this company may be had by the statement that an emergency supply of 40,000,000 bbl. for the British government was placed in storage in remarkably short time and is now available for any demand that may be made upon it. But for the difficulty in obtaining material for the construction of storage-tanks, the different companies would by this time have added enormously to their oil-stocks. The iron and steel plant at Monterrey, which was erected many years ago by a syndicate of Italians at a cost of \$10,000,000, is preparing to construct a department for the manufacture of steel plats and other materials that enter into the erection of oil-storage tanks. The Mexican government is receiving a large revenue now from the oil industry. The military protection which the independent revolutionist General Paliaz is affording to several of the larger oilfields, to the south of Tampico, and particularly those from which the Cowdray syndicate draws its supply, is still being given, much to the satisfaction of the foreign oil interests, notwithstanding that they have to contribute heavily toward the cost.

## GLOBE, ARIZONA

### SETTLEMENT OF GLOBE-MIAMI STRIKE.

William B. Wilson, Secretary of Labor, head of the Federal commission, announced on October 22 the plan whereby normal production will be resumed by the mines in the Globe-Miami district. Under the orders of the commission the strike must be called off immediately and all men who desire to return to work must report to the companies within five days. The following are the terms of the agreement:

"First—Each company will recognize a workmen's committee representing the employees, said committee to be selected from and by men actually in the employ of the company. This committee shall consist of four men representing the different departments in the same manner as the existing workmen's committee. Election shall be made by secret ballot. The method of conducting this election shall be as a majority of the workmen shall agree upon and it shall be held as hereinafter provided for. The first election of workmen's committees under this arrangement shall be held on the last Saturday of December and the term of office of the committeemen elected at that time will be from January 1, 1918, to June 30, 1918. Thereafter the election shall be held on the last Saturday of each June.

"Second—The workmen's committee shall have no jurisdiction over individual grievances until the workman has done all in his power to bring about an adjustment of the same with his foreman.

"Third—When an individual grievance is brought to the attention of the workmen's committee it shall first endeavor to bring about an adjustment between the workman and the head of the department in which he works. Failing in that it may take the grievance up with the next official in authority and in like manner to other superior officers until an adjustment is reached or the matter has been brought to the attention of the general manager. No man shall be discharged or discriminated against in his work because he does or does not belong to a union. Disobedience of the established rules of the company or of orders for the carrying out of such rules shall be cause for discharge or suspension.

"Fourth—Grievances of a general character taken up by the workmen's committee shall first be presented to the official of the company having jurisdiction of the same and if an adjustment is not reached, may be carried to the next superior officer and in like manner on through to the general manager, unless an adjustment is sooner reached.

"Fifth—If the workmen's committee and the management are unable to mutually adjust the difference in dispute they may submit the same to an arbitrator, whose decision shall be

final and binding upon both parties. There shall also be two alternate arbitrators, who shall act whenever from any cause the arbitrator is unable to act. The arbitrator agreed upon is Joseph S. Meyers, and the alternates are Hywell Davies and Judge George W. Musser. When any dispute affecting non-union men is presented to the arbitrator for decision, they may select such person as they desire to present their case to the arbitrator.

"Sixth—When any dispute affecting a union man is submitted to the arbitrator for decision, the union to which that man belongs may, with the approval of its international officials, select one of its members to present the case to the arbitrator. When any dispute affecting non-union men is presented to the arbitrator for decision, they may select such person as they desire to present their case to the arbitrator.

"Seventh—All men now on strike who report for duty within five days after the acceptance of this arrangement shall be re-employed without discrimination as soon as places can be found for them, except those who since the beginning of the strike have been guilty of utterances disloyal to the United States, or who are members of any organization that refuses to recognize the obligation of contracts, and the fact of such disloyal utterances or membership shall be determined by the arbitrator herein provided for. In re-employing workmen preference shall be given to married men and those with dependents. The placing of striking workmen reporting for duty shall be handled as a district problem.

"Eighth—The workmen's committee may make such investigations of the hospital department on behalf of the employees as it may from time to time deem necessary and make such recommendations to the trustees relative to improvements as it may find desirable.

"Ninth—It is understood that this machinery will take the place of strikes or lock-outs during the period of the War, and no other method for regulating relations between employers and employees shall be substituted except by mutual agreement."

## TORONTO, ONTARIO

### BONUS FOR COBALT MINERS.—KIRKLAND LAKE.

For some time past the iron and steel industries of Canada have been considerably handicapped by the shortage of raw material. Much construction work has been indefinitely delayed by the difficulty in procuring steel, for which the munitions plants have the first call, and the newly-developed shipbuilding industry is seriously imperilled. The situation has been brought to a crisis by the embargo recently placed by the United States government on many lines of iron and steel products, for which Canadian manufacturers look to the United States as their principal source of supply. On September 28 representatives of the leading firms using iron and steel held a conference, at Ottawa, with Sir George Foster, Minister of Trade and Commerce, at which, as a preliminary measure, a committee was appointed to ascertain from manufacturers their immediate requirements, with a view to making representations at Washington to secure a relaxation of the embargo, at least so far as regards the material needed for the munitions and shipbuilding industries. It is proposed that the limited supplies obtainable should be conserved and co-ordinated under government supervision, for which purpose an Iron and Steel Controller may be appointed with duties analogous to those of the Fuel Controller.—A representative gathering of Cobalt mine managers recently passed resolutions requesting the Government to investigate the validity of the patents of the Minerals Separation Co., with a view to their cancellation.—The general basis for a bonus directly relative to the price of silver—instead of a wage increase—to be paid to the mine-workers of Cobalt is 25c. per day on 60c. silver; 50c. on 70c. silver; and 75c. on 80c. silver.

Some of the mines pay a \$1 bonus on 90c. silver and \$1.25 when silver is at \$1, and it is understood that others will pay \$1 when silver stands at that figure. The number of men now employed at the camp is approximately 3000, and the sum total that will be thus paid out is estimated at \$78,000 per month.

The Kirkland Lake district is coming into increased prominence and attracting much attention from investors. At the Teck-Hughes the mill is running at full capacity, treating 80 tons of ore per day. The usual early difficulties in starting have been surmounted and the mill is operating satisfactorily. The winze from the 400-ft. level is down 150 ft. and when the 600-ft. level is reached, a point under the main shaft will be struck by a cross-cut and the workings connected by a raise. The company has laid out its own townsite and will erect ten houses immediately for its employees. The central shaft at the Kirkland Lake is down 20 ft. The main working has reached a depth of 700 ft. An adit run at the 400-ft. level toward the centre of the claim has proved the orebody for a distance of 600 ft., and it is expected that this orebody will be encountered by the central shaft. The Canadian Kirkland No. 2 vein is, at a depth of 25 ft., the whole width of the shaft and has a gold content of \$8 per ton. No. 1 vein has been uncovered for 400 ft. and is well mineralized.—A shaft is being put down on the Lucky Baldwin from the 100 to the 300-ft. level; the ore taken out is good-grade, carrying free gold.—Difficulties from encountering a water seam at the Croesus mine, Munro township, proved more formidable than at first anticipated, but have been overcome, and development and milling operations are now normal. The mill-head is the highest of any in northern Ontario, being over \$40 per ton.—At the Buff Munro, one mile from the Croesus, two shafts are down 50 ft. each; a mining plant is being brought in.

### OATMAN, ARIZONA

GOLD ORE.—MOSS BACK.—OATMAN GOLCONDA.

Mining operations in the Oatman district have been revived and speeded up to a marked degree during the past week. Following the hottest summer ever known in this section of the country, the beginning of the pleasant fall season witnesses a dozen important new development-projects. Summer weather in the Oatman district is usually not too hot for conducting mining activities, but the past summer has been exceptional.—Chief among the new undertakings announced recently is the work now being commenced on the Gold Ore. Control of this partly proved property has been assumed by H. E. Teter & Co., who developed the Big Jim and sold it to the United Eastern. An entirely new plant has been purchased and will be erected at the mine; the shaft will be lowered 200 ft. to the 730-ft. level; the orebody will be opened up at the 350, the 530, and the 730-ft. levels. A new road will be built to the Gold Road mill one mile distant, and at least 100 tons of ore will be mined and transported per day. The Gold Road mill has been leased for one year and will be operated on ore from the Gold Ore. The capacity of the mill is 300 tons per day and it is possible that some of the ore now being developed on the Gold Road property may be milled there. A. C. Werden, who located the Gold Ore, will be retained as manager, with A. G. Keating as consulting engineer. It is estimated that 30,000 tons of ore is already developed in the mine. Over 2000 tons was shipped to the Gold Road mill, while that plant was in operation, returning an average of \$14.50 per ton.—Development work has been resumed on the United Northern property, between the Gold Road Bonanza and the United Eastern. A shaft 550 ft. deep was sunk on this property last year and cross-cuts will be driven at the bottom. Development work will be resumed shortly on the Gold Road Bonanza, where driving along the vein at the 550-ft. level will be pushed. The drift has been advanced for a distance of 400 ft., following

a stringer averaging two feet wide.—Activity has been resumed in the vicinity of the historic Moss mine, where gold was first discovered in this district in 1864, according to tradition, by John Moss, a scout and guide employed in the U. S. Army. The old Moss property itself will be further developed by the company, of which A. C. Werden, of the Gold Ore, is president. The immense Moss vein, 200 ft. wide, can be traced over a long distance on the surface; diamond-drilling has revealed it at a depth of about 350 ft., and its further exploration should prove to be one of the most interesting projects in the district.—At the Moss Back the new owners are building a road to the property and preparing to sink the shaft 200 ft. deeper, to the 500-ft. level. The Girard property is being explored by sinking a shaft on the vein to a depth of 300 ft.—In the southern part of the district, a shaft 425 ft. deep is being sunk on the Oatman Golconda, between the Pioneer and the Leland. This mine is controlled by F. M. and H. E. Woods, of the Nellie and the Lexington-Arizona. Development work on both the Leland and the Pioneer will be started in the near future.

### MCCARTHY, ALASKA

MOTHER LODE COPPER MINE.—FRESH PROSPECTS.

The Mother Lode Copper Mines Co. has completed its new power-plant at McCarthy, built an auto-truck road from McCarthy to its lower camp, 15 miles away, and erected a concentrator unit at the lower camp which started running on October 10. It is expected that within a week regular shipments will begin; these, according to previous estimates, will amount to 30 tons of concentrate per day, carrying 50% copper and 3 oz. silver. To secure this product 200 tons of ore will be mined and delivered by the 6000-ft. aerial tramway into a gyratory crusher, reducing it to  $\frac{1}{4}$ -in. mesh, thence through a trommel screen, where it is sized, thence to a Woodbury jig, that makes a high-grade product only. The tailing from the jig is saved for re-treatment in a permanent mill that is to be built next summer. The power-plant just completed at McCarthy generates 240 volts, stepped-up by the two transformers to 16,500 volts, then stepped-down again to 440 at the lower camp and to 220 volts at the mine. For this purpose five 500-kva. and two 100-kva. transformers are used, two 500-kva. transformers being used at the power-plant, two at the lower camp, and two 100-kva. at the mine, providing for changing from two-phase to three-phase; the fifth transformer is kept as a spare one. The telephone line is now in operation to the mine. The wagon-road, also just completed, is substantial and good, and it is graded either on the gravel bars of McCarthy creek or in rock side-cuts. In crossing McCarthy creek there are three double-truss bridges and 12 single-truss deck-bridges, besides 16 log bridges and 34 culverts. A two-story building 60 by 40 ft. has been erected at the lower camp. The office building is of two stories, 30 by 36; the ground floor contains a general office, the president's office, and commissary; there are four bed-rooms on the upper floor for the use of the officers. At the mine 212 ft. of development work has been driven during the past summer, making in all upward of 8000 feet.

A new and important copper strike is reported to have been made during the past summer by M. B. Vaughn and M. V. Fox near the head of the McLaren, in the Susitna water-shed, about 50 miles from Yosts' on the Government Fairbanks-Chitina trail. The location will be about 100 miles from the Government railroad, when it is completed through to Fairbanks. The vein is said by the locators to be in amygdaloid greenstone, is from 2 to 10 in. wide, maximum width shows on the surface for about 40 ft., while the vein can be traced for 300 ft. The samples of the ore shown by the locators, which they claim to be a fair average of the vein, is a good-grade chalcoppyrite, about 20% copper content.

## ALASKA

(Special Correspondence.)—W. W. Logan, who for the past season has been superintendent of the Gold Bullion cyanide plant, came in from the mine and sailed for San Francisco on the 'Alameda'. Under Mr. Logan's management the Gold Bullion, which is the farthest north of any cyanide plant in America, handled the greatest tonnage and had the most successful season since it started. Henry Landers is in town from the Gold Bullion with a clean-up from that property. The Gold Bullion was the first producer in the Willow Creek district. It is under lease to a company of Canadian capitalists, who, it is reported, will make a substantial payment on the property this fall. The company is arranging to work a crew of men all winter in developing the mine.—The Willow Creek Development Co. has made a shipment of ore to Falkenburg & Laucks, of Seattle, who will make a thorough test and design a mill for treating it.—The Government railroad has already borne fruit in rendering the Willow Creek district accessible. It can be reached now from Anchorage in a day, while a year ago the journey required four days. This has resulted in increased activity in the district and bright prospects for the coming year.—The Cache Creek placer district will be rendered accessible when the railroad reaches Talkeetna, and the Alaska Road Commission completes the road from that place to McDougall, which is now being laid out by Ross Kinney.—Hershel Parker, who has reported the discovery of platinum in commercial quantity in the gravels of the Kahittna river, left for New York on the 'Alameda' tonight.—M. A. Ellis of the Thunder Creek Mining Co. is in town attending to the transportation of supplies for his company's operations next year. He reports a very successful season and is preparing for extensive operations next year.

Anchorage, October 8.

Louis C. Dillman, a Seattle capitalist, announced on October 20 his sale of the West Over group of copper mines in southwestern Alaska to the Alaska-Chitina Exploration Co. of Seattle for \$416,000 in bonds and cash. F. A. Seiberling, president of the Goodyear Rubber Co. of Akron, Ohio, is reported to be interested in the purchasing company.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—Sinking has commenced in the Cochise shaft of the Copper Queen company to develop more water to operate the proposed new concentration plant planned to treat 15,000,000 tons of low-grade ore, the tests for which are now nearly complete. A large tonnage of chalcocite ore has been developed as a result of several years' drilling operations in the granite porphyry mass of Sacramento hill.

Bisbee, October 12.

(Special Correspondence.)—The Arizona Commercial Mining Co. has completed a lot of repair work and is now producing at about 75% normal. Additions are being made to the pumping and hoisting equipment.

Globe, October 12.

### GRAHAM COUNTY

The Copper Reef mine, in the Stanley district, has recently

been doing new development work that is proving productive. The mine has been opened by a long adit, and by winzes. A new orebody was disclosed by a cross-cut 200 ft. long, driven under the direction of the superintendent, Leonard W. French. Shipments of ore averaging about 12% copper are now being made through San Carlos.

### MOHAVE COUNTY

(Special Correspondence.)—Lessees have taken 3000 oz. silver ore from the White Hills property, 30 miles north of Chloride. This property has been idle for some time. The same lessees took out a small fortune from this property some years ago. Molybdenum ore, estimated at 4% sulphide, has been uncovered at a depth of 285 ft. in the shaft of the New Tennessee mine. Traces of this ore came in at the 270-ft. level.—H. B. Tetor & Co., developers of the Big Jim mine, have assumed control of the Gold Ore property. The present 520-ft. shaft will be sunk another 200 ft. and levels driven at 200-ft. intervals. The ore will be treated at the Gold Road mill, a mile away, until the Gold Ore mill is ready to handle it. It is estimated that the Gold Ore has some 30,000 tons of milling ore developed.—Preparations are being completed for resuming work on the United Northern property. A new engine and compressor have been purchased, and, as soon as erected, the 500-ft. shaft will be sunk another 100 ft. and drifts started.

Kingman, October 20.

(Special Correspondence.)—The Keystone mill, comprising a Blake crusher, a ball-mill, an Aikin classifier, 10 roughing and 3 cleaning flotation-cells, a Dorr thickener, settling-tanks, and drying-bins, is working perfectly, and turning out a concentrate averaging 100 oz. in silver, \$7.50 gold, and 6% copper. At present the mill is running one shift per day on dump-ore.—The New Mohawk has erected a 35-bp. hoist on shaft No. 2, where a vein of high-grade silver ore has been cut.—The Schuykill mine has started to ship ore. The shaft is down 800 ft. and levels are being driven at 400 and 800 ft., respectively. The Schenectady mine is driving on the vein at the 200-ft. level.

Oatman, October 19.

A. M. MacDuffee, mineral commissioner of this county, has been gathering specimens for exhibit for the fairs at Prescott and Phoenix. He has visited nearly every mine in the district.

The Jamison mine, controlled by Lauzier & Walcott of Butte, Montana, Charles McKinnis of Wallace, Idaho, and F. Kays of Kingman, Arizona, is being developed rapidly; the main adit, which is driven on the vein, is about 800 ft. long and has been in ore from the start.—The Golden Hammer has a good showing of high-grade ore on the dumps. New hoisting machinery is being erected. The orebody has been proved for 600 ft. without a break, and is 5 ft. wide. The ore runs about \$40 per ton. This property is under bond and lease by W. B. Twitchell of Phoenix and F. C. Smith of Chloride.

In the George Washington mine, owned by the Washington-Arizona Copper Co., of which Elmer D. Reece is president and manager, the development consists of an adit 960 ft. long ex-

posing the vein the entire distance, with several stopes, a winze 100 ft. deep, two 50-ft. raises, and several cross-cuts. Two other adits farther up the hill show milling ore; these adits with the cross-cuts will measure about 2000 ft. The mine is well timbered, electric lighted, and equipped with modern machinery. The mill has just been put in operation.

The Town mine is shipping a couple of cars of ore to the Needles smelter, which is reported to average \$50 per ton.

#### PIMA COUNTY

(Special Correspondence.)—Engineers have examined the Vulcan property in the San Xavier-Twin Buttes district for possible Eastern purchasers.—The northern part of the property of the Swastika Copper & Silver Mining Co., in the same district, has been sold for \$125,000. Negotiations are pending for the sale of the four remaining claims.

Tucson, October 21.

#### PINAL COUNTY

(Special Correspondence.)—The Climax Hill shaft of the Troy Arizona Copper Co. is down 377 ft. and indications point to an early penetration of the sulphide zone. F. C. Armstrong, president of the Arizona-Hercules Copper Co., has taken an option on the Pinal Consolidated mine, a silver-lead property, formerly known as the Silver Bell.

Florence, October 22.

#### YAVAPAI COUNTY

(Special Correspondence.)—It is reported that 20% ore is being mined on the Jerome Verde, 10 ft. north of the United Verde extension line. Ore from this area is now being hoisted through the Edith shaft of the United Verde Extension.

Prescott, October 21.

Some of the richest gold ore ever seen in Yavapai county has been found on the Rosa Mary group of five claims owned by John Revello. How much of this ore will be found on the property is a matter of conjecture, but Mr. Revello recently extracted 39 lb. of the richest ore and sent it to the Selby smelter, and he received the firm's check for \$1704.20. The fortunate owner also put three tons of what he calls second-grade ore through an arrastra and recovered \$620. There is also a quantity of ore which has assayed from \$12 to \$15 per ton. The property is situated in the Crown King district, near the famous Monte Carlo property.

#### YUMA COUNTY

(Special Correspondence.)—The Mohican Copper Co. has completed 512 ft. of sinking and 1200 ft. of driving. The people controlling the Mohican property have taken over the Groundstone group of gold claims three miles from Alamo springs.

Yuma, October 12.

### CALIFORNIA

#### ELDORADO COUNTY

(Special Correspondence.)—Preparations are under way to erect a stamp-mill on the Montezuma lode mine, on the Mother Lode, in the Nashville district, 11 miles west of south from Placerville. The Montezuma, which is developed by a shaft 1000 ft. deep and drifts north and south on the vein at each 100-ft. level below the 500-ft., is owned by J. Cam. Heald, Mayor of Nashville. The Havilla lode mine, situated just south of the Montezuma, is being re-opened and the stamp-mill is being re-constructed. San Francisco capitalists are financing the reviving of the Havilla.—The Washington & California Gold Mines Co., of Seattle, is starting operations on its gold quartz properties, which are on the main Mother Lode of California, a short distance from the Montezuma mine. A 5-ft. vein of high-grade quartz, showing gold, was recently uncovered in sinking a shaft on one of the claims owned by the company.—Farther north on the Mother Lode, near the

Martinez group of gold quartz claims, Antony Crafton is developing a group of quartz claims, which he has under lease and bond for Seattle capitalists from Grant Busick, an old-time miner. This property contains a fair tonnage of low-grade gold ore.

Robert G. Hart, mineralogist, who is making a systematic investigation of the Placerville Quadrangle for ores containing rare metals, left this morning for a three-day trip to the north part of Eldorado county to examine and sample a deposit of high-grade molybdenite.

Placerville, October 25.

#### FRESNO COUNTY

(Special Correspondence.)—Operations at the reduction plant of the Piedra Magnesite Co., at Piedra, 30 miles east of Fresno, began September 21. The construction of the plant, which is one of the most up-to-date of its kind on the Pacific coast, was begun early in July. The plant has a capacity of about 60 tons of calcined magnesite per day, which is equal to a little more than twice that amount of raw material. The plant represents an investment of approximately \$55,000. Thomas J. Curran, manager for the American Magnesite Co. at Porterville, Tulare county, is general manager for the company. J. W. Thomas of Porterville is treasurer and W. B. Phillips, also of Porterville, is superintendent. The calcining kiln is of the rotary type, 83 by 8 ft., and weighs about 80 tons. The cooling-tower is 60 ft. high and the mineral is carried to the tower from the kiln by 125-ft. chain-bucket conveyors. The mineral is first fed into a heavy gyratory crusher from which it passes through a screen into the ore-bin and then into the kiln. The screen allows only mineral that is finer than a large pea to pass into the kiln, thus ensuring rapid and thorough calcination. The large pieces are returned to the crusher. All machinery about the plant is run by electricity. The Piedra Magnesite Co. owns 11 mining claims and employs more than 100 men. The mine is about half a mile from the plant which is on the bank of the Kings river. The mineral is hauled from the mine to the plant on auto trucks. The output has been contracted for by the American Refractories Co. of Pittsburgh, Pennsylvania.

Fresno, October 24.

#### PLUMAS COUNTY

The Walker mine and mill are being worked to capacity once again, after a strike started by I. W. W. agitators. There are 200 men on the payroll at the mine and 30 men making a connection with the electric line of the Great Western Power Co., 15 miles away.

#### SAN BERNARDINO COUNTY

The California Supreme Court has upheld the Superior Court of San Bernardino in the case of R. Waymire v. the California Trona Co. This confirms the title of some 20,000 acres, known as Searles Lake, in the California Trona Co. The decision has no bearing on the Government case against the Trona company, which is still pending. The Government has charged that the company is an alien corporation, because most of the stock is owned by the Consolidated Gold Fields of South Africa, represented by Lord Brabourne and Baron de Ropp, and therefore should not be granted a patent to the lands. Searles Lake, a lake during the rainy season only, contains both potash and borates, and, on account of the great need for the former for agriculture and munitions, the case is exciting considerable interest.

#### TRINITY COUNTY

In a recent clean-up from his mine on Coffee creek, Patrick Holland found three nuggets, valued at \$1155, \$600, and \$155 respectively. These are the largest nuggets that have been found in the county for a number of years. The rest of the clean-up amounted to \$600 and contained several nuggets over \$50 in value.

PIEDRA MAGNESITE PLANT, FRESNO COUNTY, CALIFORNIA

**SHASTA COUNTY**

The Shasta Hills Mining Co. is erecting a five-stamp mill at the Sybil mine, three miles west of French Gulch.

**COLORADO****BOULDER COUNTY**

(Special Correspondence.)—A number of old mines are being re-opened in the Caribou district, and some new discoveries have been made.—F. G. Albrecht, one of the pioneers of this camp, has opened up a fine body of high-grade silver ore.—Guy M. Woodring, vice-president of the Huron mine at Eldora, has purchased an air-compressor for the property; it will be put in this week.—A new mill is being erected by the Consolidated Mining Co.—The Good Morning adit at the Wall Street has tapped a large vein of low-grade silver and gold ore. F. H. Hammond is the foreman. An electric-drill outfit has been put in.—W. W. Degge, who built a refinery at Boulder, has returned from the oilfields of Wyoming, and will again start business at the oilfields of the Boulder company.—The Great Britain & Emerson property at Wall Street has been taken over by a new company, which will push operations on a large scale.—The Doss adit at Wall Street is getting out some rich gold ore; steady shipments are being made.—A large force of men is employed at the Fairfax mine, at Salina.—The Melvina mine, west of Salina, an old-time producer, will be opened up by A. Murphy, who has just arrived from Arizona.

Eldora, October 22.

**SUMMIT COUNTY**

The Tonopah Placers Co. shipped a gold brick valued at \$8100 on October 10 to the United States mint at Denver. It was the result of a previous 10 days run of one of the company's three gold dredges.—The Wellington Mines Co. produced in September about four carloads of heavy lead concentrate in addition to its regular output of zinc concentrate. The company issued dividend checks to the amount of \$100,000 on October 1.—The Carbonate, on Mount Baldy, shipped three carloads of lead carbonate ore during the first ten days of October. The ore, besides running high in lead, carries considerable gold and silver. The property is operated through an adit several hundred feet above the timber-line.—The Iron Mask mine, operated by the Mid-West company, shipped a carload of carbonate ore last week to a smelter. The Iron Mask is operated through a main adit 1500 ft. long. At 1300 ft. from the portal, in a winze, sunk below the adit-level, a 3-ft. body of lead ore has been opened.

Paul Burdette, lessee of the Ella on Mineral Hill, shipped a carload of lead-silver ore last week. The Ella is controlled by the Wellington-Crescent Co. The Minnie mine, also con-

trolled by this company, is being worked under lease by E. E. Miller and associates.—A discovery of wolfenite has been made by George Dunnigan on Peak No. 9 of the Ten Mile range, opposite the Breckenridge townsite.

**IDAHO****SHOSHONE COUNTY**

The Hecla mine, at Burke, Idaho, which is paying monthly dividends of \$150,000, will soon be improved by the addition of storage bins, a sorting-plant, and a change-room for 500 employees. The bins will accommodate the daily production from the mine; they are designed to make possible a continuous flow of ore through the sorting-plant and mill when delays occur elsewhere. The Hecla is steadily extending its levels and increasing its production and reserve. The ore-reserve is estimated to be four to five years in advance at the current rate of output. Of the 1000 tons hoisted daily from the lead-silver bodies about 75% is ore.

An October dividend of \$78,150 has been declared by the directors of the Caledonia mine in the Coeur d'Alene, bringing the disbursements to stockholders for the current year to \$859,650 and the total since the mine entered the dividend-paying class of \$2,753,150. The surplus on August 31 was \$719,183. The net earnings during September were \$117,000, and it is estimated that the surplus at the present time is in the neighborhood of \$800,000.

**MISSOURI****JASPER COUNTY**

The structural portion of the new 200-ton mill of the N. J. & D. Mining Co., situated on a lease of the Walker land, just north of Duenweg, is rapidly nearing completion. A boiler has been set and machinery is being erected in the new concentrator. Construction work was begun early in September and the members of the company plan to have the mill completed within a month. The shaft is being shaped up for operation by the time the plant is ready to run. The company has sunk a new shaft and opened up some good lead and zinc ore. Below the 160-ft. level 20 ft. of ore was proved by drill-holes. C. E. Laplant is superintendent and part owner of the mine.

**MONTANA****LEWIS AND CLARK COUNTY**

(Special Correspondence.)—The Amalgamated Silver Mines, a Montana corporation, has secured the Free Coinage claims in Lump gulch, together with the Alma and Muskeegan claims, and has, in addition, located 25 claims adjoining. Three shafts, 180, 200, and 350 ft. respectively, are available. The present

work consists in opening and deepening the 180-ft. shaft on the Free Coinage. A hoisting and pumping plant has been installed and the shaft re-timbered to water-level, previous to sinking another 100 ft. Silver ore to the value of \$12,000 was mined from this shaft in the past. The ore averaged 115 oz. per ton and carried over 20% zinc. The company is composed of New York and Montana people and is capitalized at \$1,000,000 in dollar shares. The veins are in granite, 10 miles from the smelting works and 1½ miles from the railway.

In the old Park district, Broadwater county, considerable work is being done. New buildings are going up. A new road is being made to connect with the main wagon-road from Hassel to Townsend. The ores contain silver, lead, and gold. The ground is very wet and requires machinery to control the water.—The Helena mine, operated by the Helena Mining Bureau, has shipped its twentieth carload and has a large tonnage blocked on the 300-ft. level, the present depth of the mine.

—The Economy Mining Co. has unwatered its 300-ft. shaft and is taking out high-grade gold ore. The plant is operated by electric power.—Negotiations are pending for the treatment of a large tonnage of manganese ore from Senator Clark's mines at Butte. The New York-Montana Engineering & Testing plant at Helena wants the ore for concentration, but nothing will be decided until Senator Clark returns to Butte.

Helena, October 26.

## NEVADA

### HUMBOLDT COUNTY

(Special Correspondence.)—The gross earning of the Rochester Mines Co. for the quarter ended September 30 totaled \$158,883, and net profit was \$64,690; 15,908 tons of ore was milled, averaging nearly \$10 per ton. The mill is now treating 217 tons of ore per day with most of it coming from the Adams vein on the 800 and 900-ft. levels. On the 800 the vein has been opened for 500 ft. and ranges from 12 to 32 ft. wide. On the 900 it has been developed for 200 ft. and is from 13 to 40 ft. wide. The ore on both levels ranges from \$8 to \$35 per ton. Mill-ore is under development on the 250 and 650-ft. levels, and from the 900 a winze to open the Adams vein on the 1100 is progressing. A bullion shipment worth \$34,000 was made October 5.—The Nevada Packard Mines Co. is preparing to sink a shaft to the sulphide zone from the main adit which opened ore at a depth of 200 ft. Work has been resumed in the Kromer-Hampton section and ore averaging \$10 per ton is being mined. A considerable tonnage of \$8 to \$10 ore has been opened in the Griffin and Margrave cuts.—Construction of the 300-ton mill of the Rochester Combined Co. has been nearly finished, but delayed shipments of electrical equipment will prevent ore-crushing until December. Excellent ore continues to be mined from the 100 and 200-ft. levels of the Happy Jack shaft, and from the Shepherd and Kromer adits. Prospecting of outlying claims is proceeding.—The Nenzel Crown Point and Buck & Charley have arranged with the Nevada Short Line railway for steady shipments to custom smelters. Some ore will be sent to the Hazen sampling-plant, and negotiations are proceeding for shipments to the Mammoth smelter at Kennett, California. The Nevada Short Line has purchased a new locomotive and is preparing to handle shipments for several companies.—The Bloody Canyon antimony mine and adjacent holdings near Unionville have been acquired by the Pioneer Extraction Co. of San Francisco. Ore will be treated in a mill, being constructed at Mill City. Besides a large tonnage of milling-ore, considerable shipping material has been uncovered. Homer Wilson is president and general manager.—The Darby mill, at Mazuma in the Seven Troughs district, has been purchased by George W. Forbes and Brooke Hartley and will be operated on custom ore, besides treating the product of the Hero and Wildcat mines at Farrell, which are leased by the mill-owners. Arrangements have been made to crush ore from the Fairview property, Vernon, and from the large

dumps at the Mazuma Hills group.—The silver district recently discovered eight miles south-east of Lovelock is attracting favorable attention. A shipment of high-grade ore will be made from the Badger group, operated by M. Farretta. A dozen promising claims are being prospected and rich ore exposed at several points.

Lovelock, October 22.

The American Exploration Co., through F. H. Vahrenkamp, its president, announces that it has just closed a contract with the Magnolia Metals Co. of New York, aggregating \$6,000,000 for antimony to fill government orders. These call for shipments of at least 500 tons of antimony per month and as much more, up to 7500 tons, as it is possible for the company to produce. As a start toward filling the contract, preparation is being made to re-open the Imlay properties at Imlay, and a 200-ton mill is nearing completion.

### MINERAL COUNTY

Definite plans for the development of its property comprising the old Moho group of claims in this county were announced recently by the Western Silver Mines Co., a concern recently incorporated in this State. The property is six miles from the line of the Southern Pacific railroad, and not far from the town of Mina. It comprises ten lode-mining claims and a mill-site and, according to those interested, shows four separate veins, one of which, the Moho, has been opened for a distance of approximately 4500 ft., while another, the Shoemaker vein, has been opened for about 1500 ft. These veins are said to show an average width of 4½ ft. that runs \$9.43 per ton.

### NYE COUNTY

(Special Correspondence.)—The Nevada California Power Co. has completed its large auxiliary electric-power plant and given it a thorough test. The generators are operated by steam and the plant will enable the company to supply local mines with abundant power should storms demolish the transmission lines between here and Bishop, as happened last winter. Completion of the plant also insures steady work at the Great Western and West Tonopah mines. Both properties are being explored by a long cross-cut, which is being driven by the Western Tonopah company, composed largely of Boston and Butte capitalists.—The employees of the White Caps and White Caps Extension companies at Manhattan are on strike, following refusal of the companies to grant the Tonopah wage-scale, a minimum of \$5 per day. The strike affects mines and mill. The Morning Glory, Consolidated, and Union Amalgamated granted the wage asked and are operating with a full crew. Some operators maintain they will close for the winter rather than grant the demands of employees.—The Bullfrog district again claims attention. The Sunset company is vigorously working the old Tramps Consolidated group and recently found ore assaying \$20 per ton at a depth of 450 ft. The vein is a part of the Denver and is five feet wide. With the mill-ore occurs a streak assaying \$270 per ton.—The Mayflower company has been re-organized as the Consolidated Mayflower Mines Co. Ore assaying \$6 to \$50 per ton is going to the 15-stamp mill, operated by a 35-hp. Fairbanks-Morse engine. An eight-drill Ingersoll-Rand compressor is driven by a 90-hp. Western gas-engine. Leasing operations have begun on the Montgomery-Shoshone and other properties. In the Pioneer section considerable activity is reported.

Tonopah, October 14.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—The Socorro M. & M. Co. is increasing mill tonnage; the past week being one of the largest so far made. October output to date is several hundred tons ahead of normal. Ties for the new narrow-gauge railroad to

the Johnson mine are being cut and delivery will begin next week.—The Oaks Co. has increased its development and ore breaking on the Central group. A considerable tonnage is awaiting shipment to mill.—Business men of Clifton, Arizona, are working to secure the connection of Clifton and the Mogollon district by a State highway. This will shorten freight and passenger service and is receiving encouragement from Mogollon people.—Miners are scarce generally through-

## OREGON

### JACKSON COUNTY

(Special Correspondence.)—Herbert Brewitt of Tacoma, Washington, representing investors of that city, has taken a lease on the Truit manganese deposits in the Eagle Point district, 20 miles north-east of Gold Hill. The lessees have done considerable development work on the property and ordered machinery for a concentration plant, and 40,000 ft. of lumber from a mill-building. C. F. Daugherty, examiner and buyer for the Noble Electric Steel Co. of San Francisco has been examining manganese properties in this district during the past week.—Clark & Webb of Medford have leased the Gold Ridge gold and silver mine, three miles south of Gold Hill, on Kanes creek. The lessees are operating a three-stamp mill and making further developments on a 20-ft. vein that averages \$100 per ton in gold and silver. The vein is in a gabbro-porphry contact and is free-milling.—The owners of the Copper King copper mines on Graves creek have re-organized and operations have been resumed at the mine. New equipment will be added and a wagon route from the mine to Rogue River, nine miles west of Gold Hill, is under construction. A large body of ore has been uncovered recently.

Earl M. Young of Rogue River has sold his manganese property, 12 miles west of Gold Hill, on Evans creek, to Seattle steel people, who will develop the mine. The ore occurs in small seams, running 35 to 50% manganese. Operations have been resumed on the Nellie Wright gold mine, two miles east of Gold Hill, after a close-down of two months pending reorganization. The 25-ton Beers mill will be replaced by a larger and more modern one. R. M. Wilson is the lessee, representing San Francisco investors. Development work is progressing favorably on the Cheney, Simmons, Ray, and Haff gold mines, two miles north of Gold Hill. This group is being operated by J. W. Davies for Sacramento people.

Gold Hill, October 22.

(Special Correspondence.)—The first modern quicksilver furnace has been completed and is in operation in this county. It is situated 12 miles north of Gold Hill, at an elevation of 2500 ft., on the slope of the Umpqua mountains in a heavily timbered district. The mines are owned and operated by W. P. Chisholm of Gold Hill, and consist of 40 acres, which have been

mined for cinnabar since 1878, but the ore has been reduced in only a crude way.

The vein, which strikes N. 53° W., has been exposed by adits for 2000 ft.; the greatest depth attained is 75 ft. It occurs along a granite-sandstone contact, where the granite is in part pegmatitic. The mineralized zone is from 100 to 200 ft. wide; it is not a well-defined vein, but is mineralized along an irregular contact. The ore, or mass, contains cinnabar, native mercury, pyrite, gold, zinc, silver, and a heavy black mineral resembling meta-cinnabarite. Samples taken from all the adits assay from \$5 to \$6 per ton in gold, 5 oz. in silver, 2.5% zinc, and 1% mercury. The cinnabar appears all through the

FRONT VIEW OF MERCURY FURNACE AT CHISHOLM MINE, OREGON

BACK OF MERCURY FURNACE AT CHISHOLM MINE

out the district and the increasing work offers employment for good men.

The local bullion production for the first 15 days of October amounted to about 33,000 oz., containing one-third gold, two-thirds silver.—Development on the east 900-ft. level at the Mogollon mine is steadily improving. This drift is entering the same orebody that was developed on the 700-ft. level.—The new strike in the Maud S. mine on the Oaks Co. property is being opened from two sides and the value and width of the ore continue to increase.—Fifteen men are working on the Whitewater road for the Socorro M. & M. Company.

Mogollon, October 23.

ore and also in the hanging and foot-walls in the form of seams and kidneys. The seams are from 6 to 20 in. thick and average from 17 to 70% mercury.

The initial run of ten tons of ore in the new furnace produced three flasks of quicksilver; 1200 lb. of this ore was taken from a rich seam that runs as high as 70% quicksilver. With recent developments in the mine there is 5000 tons of ore in the block. The furnace, a 12-pipe Johnson and McKay, is placed within 300 ft. of the main adit.

Gold Hill, October 25.

#### JOSEPHINE COUNTY

(Special Correspondence.)—A deposit of chrome ore has been discovered on the old McGrew road, 15 miles south-west of Waldo, by J. H. Gregg, and is being hauled to Waters Creek for shipment.—The chrome claims located on Canyon creek, near Kerby, a few weeks ago by J. M. Finch and T. P. Johnson have proved to contain a large deposit of high-grade ore. The ore will be hauled to Waters creek.—A carload of chrome ore has been shipped from the Falls Creek district by W. E. Gilmore of Kerby. The ore was packed several miles on horses.

Kerby, October 26.

#### TEXAS

The Toyah Valley Sulphur Co., Seaton Keith, president, J. A. Daniel, secretary, and Ira Fisdale, treasurer, all of Houston, has been organized to develop a 1200-acre sulphur property.

#### UTAH

##### SUMMIT COUNTY

A deposit of sulphur has been discovered in a mine, nine miles south-west of Coaldale, that was originally opened by Boston capitalists for potash and alum. Some of the ore runs as high as 95% sulphur.

## Copper Share Dividends

In the first nine months of the year there was paid out to copper shareholders approximately \$139,000,000, against \$108,000,000 in the same period of last year..

The principal copper-share dividend payers and the amounts distributed throughout the first ten months of the past two years appear in the following tabulation:

	1917	1916
	Amount per share	Amount per share
Allouez	\$9.00	\$4.50
Shattuck-Arizona	8.75	1,225.000
Oseola	18.00	1,057.650
Ahmeek	12.00	1,700.000
Granby	7.50	749.924
Isle Royale	5.00	300.000
North Butte	2.25	752.500
Anaconda	6.50	11,656.250
East Butte	1.00	411.000
Mohawk	20.50	1,700.000

# PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

H. H. WEBB is at the Fairmont hotel.

DAVID W. BRUNTON is on a visit to New York.

C. C. BROADWATER is on his way to New York.

GARDNER WILLIAMS has returned to Washington.

GEORGE E. FARISH sailed on October 2 for Salvador.

L. D. RICKETTS is making a tour of inspection in Arizona.

C. H. DOOLITTLE is here, having motored from Salt Lake City.

A. G. HARBAUGH is here from Belleville, in the Candelaria district.

JOHN A. DRESSER, of Montreal, has gone to El Paso, thence to Tennessee.

NORMAN PICOT sailed on the 'Sierra' from San Francisco for Melbourne.

E. H. HOAG has returned from San Francisco to Cosala, Sinaloa, Mexico.

CURTIS WEBB has returned from Morococha, Peru, to serve in the Aviation Corps.

CHARLES E. PRIOR has obtained a commission as First Lieutenant in the Army.

W. C. RUSSELL, general manager for the Caribou Mining & Milling Co., is at Denver.

C. E. ARNOLD, engineer to the Inspiration Consolidated Copper Co., is here from Miami.

HAROLD C. CLOUDMAN has been commissioned a Captain in the Engineer Corps, U. S. Army.

THOMAS CARLYON has resigned his position with the Keweenaw company and retired to Houghton.

G. L. SHELDON recently made a professional trip through Eureka, Lander, and Nye counties, Nevada.

R. D. PARK, of the United Verde mine, has received a commission in the Engineer Corps of the U. S. Army.

WALTER R. VIDLER has returned to Colorado from professional work near El Paso, Texas, and Nogales, Arizona.

H. VINCENT WALLACE is at Tucson; he is now consulting engineer to the Guanajuato Development Company.

JAMES F. BROWN has been commissioned in the Ordnance Department of the Army, and is stationed in Illinois.

L. O. HOWARD has been appointed Dean of the School of Mines of the State College of Washington, at Pullman.

I. J. RUSSELL has resigned as superintendent for the United Gold Mines Co., and has gone to the oilfields of Oklahoma.

W. N. THAYER has returned to Cincinnati from the Wyoming oilfields and has left for the Vermilion district in Minnesota.

D. L. MCCARTHY, superintendent for the Granite Gold Mining Co., is seriously ill at the Glockner Institute, Colorado Springs.

JOHN BAILEY is acting in his stead.

J. H. WINCHELL, JR., has resigned as engineer for the Deming Mines Co. to become junior land-classifier for the U. S. Geological Survey, and is stationed at Sterling, Colorado.

A. C. BARKE has become engineer to the U. S. Mining, Smelting & Refining Co.'s exploration department, in succession to ALBERT ROBERTS, who has joined the Minerals Separation staff in San Francisco.

HENRY A. WENTWORTH has been appointed a vice-president of the American Zinc, Lead & Smelting Co. He will take charge of the Exploration Department recently formed for the investigation of new properties and processes.

ALBERT BURCH has been elected president of the California Metal Producers Association for the current year. G. W. METCALFE is first vice-president and ROBERT I. KERR secretary-treasurer, with EDWIN HIGGINS as safety and efficiency engineer.

# THE METAL MARKET

## METAL PRICES

San Francisco, October 30

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	16.00
Antimony (wholesale), cents per pound.....	14.75
Electrolytic copper, cents per pound.....	23.50
Pig-lead, cents per pound.....	5.75—6.75
Platinum, soft and hard metal, respectively, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	100
Spelter, cents per pound.....	9.50
Tin, cents per pound.....	60
Zinc-dust, cents per pound.....	20

## ORE PRICES

San Francisco, October 30

Antimony, 45% metal, per unit.....	\$1.10
Chrome, 34 to 40%, free SiO <sub>2</sub> , limit 8%, f.o.b. California, per unit, according to grade.....	\$0.50—0.60
Chrome, 40% and over.....	\$0.60—0.75
Magnetite, crude, per ton.....	\$8.00—10.00
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.	
Tungsten, 60% WO <sub>3</sub> , per unit.....	26.00
Molybdenite, per unit MoS <sub>2</sub> .....	\$40.00—45.00

## EASTERN METAL MARKET

(By wire from New York)

October 30.—Copper is unchanged and nominal at 23.50c. all week. Lead is more active and firm at 6.25 to 5.60c. Zinc is dull and weaker at 8.25 to 8c. Platinum remains unchanged at \$105 for soft metal and \$111 for hard.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Samuel Montagu & Co., of London, report that the silver market has been inert, and in the absence of any important buying orders the movement of prices has been again retrograde. The prohibition of exports to certain neutral countries, as from October 8, is hardly likely to have much effect upon the market except so far as any additional restrictions tend to hamper business. The return of the price to a lower level is in favor of the Indian government, which is undoubtedly in a position to use large quantities of silver when it can be secured advantageously. The Indian currency returns record an increase of one crore (10,000,000 rupees) in the holdings of silver.

The High Commissioner for Canada has stated that "Since the discovery of silver in Cobalt in 1903 there has been produced approximately 266,000,000 oz. of silver, valued at \$143,000,000. It is estimated that this year's production will have a valuation of \$15,000,000. If this be calculated at the average price of the first six months of this year, the weight should equal about 19,600,000 oz., implying a reduction of about 6,400,000 oz., or about 25%, on the Government estimate of 26,000,000 oz. for 1916.

Chile Copper Co. states that reduced production in September of 3,294,

000 lb., as against 8,036,000 lb. in August, was due to inability to secure deliveries of Californian and Mexican fuel-oil, and to the shortage of Chilean coal, which conditions persist.

## LEAD

Charles Hardy says: Manganese ore remains in good demand. Such ore as reaches our market from abroad finds ready buyers. The basis for 48% material is still \$1, and chemical ore of good quality is sold in large quantities at prices of about \$100 per ton.

High-grade chrome still remains firm at 90c. per unit f.o.b. Western Coast shipping point and the market is considered firm.

The magnesite market continues practically the same with \$40 per net ton f.o.b. California quoted for high-grade calcined magnesite. Small business, however, has been reported.

Californian virgin quicksilver is still quoted at \$100 per flask, but very little spot material is available. Mexican and recovered is sold at the regular discounts from the Californian virgin price.

The United States Geological Survey is gratified to report a new source of the much-needed war mineral, chromite. J. T. Pardee, of the Survey, found it in serpentine while hunting for platinum and manganese on Cypress island near Anacortes, Washington. Some of the chromite has recently been shipped to an alloy company at Tacoma, and it is probable that on account of its nearness to tide-water the Cypress Island locality may become an important producer of chrome ore.

# Eastern Metal Market

New York, October 24.

The markets continue inactive. Uncertainty pervades nearly every department and buying is only from hand to mouth.

Copper is still unsettled and nominal at the Government price.

Tin is firm and steady but there is little demand.

Lead has fallen again and there is almost no buying.

Zinc continues stagnant with no change.

Antimony is in poor demand and a little lower.

Aluminum is quiet and unchanged.

More active buying is apparent in the steel market at the new prices, especially in pig-iron. Further announcements of new prices are not expected, but it is probable that the trade will adjust itself to the new levels on other commodities not already stipulated. It is felt generally that a broader and more active market, as well as a healthier one, is in prospect.

## COPPER

The entire situation continues unsettled. Reliable or official information concerning the market is extremely difficult to obtain. The producers' and consumers' committees are making no announcements, but it is believed they are rapidly working out a satisfactory solution so far as large producers and consumers are concerned. The main object is to conserve supplies so that war-needs may be adequately met, but how much is to be left after these are satisfied is not known to the public. Some predict a shortage; others an over-production. It is believed that large consumers, especially if they have Government work to carry out, are getting supplies on old contracts. The position of the small dealer and of the consumer that usually buy small quantities is difficult. The statement is made that sales by such dealers at a price higher than the Government figure are subject to confiscation. If this has any basis in fact, it will put small dealers and consumers in a serious position so far as continuing their business is concerned. It is true, however, that small lots of copper have sold as high as 30c. per lb., New York. It is also a fact that copper in large quantities cannot be bought at the Government price nor at any other price. The entire market is stifled and inactive. We continue to quote the official rate of 23.50c., New York, as nominal for all grades of copper. The London market is unchanged.

## TIN

The tin market has been firm and steady since our last letter, though little business has been reported. Prices have fluctuated closely on either side of 61.50c., New York, on each day. Yesterday the quotation for spot Straits was 61.62½c., New York. The last three days of last week were very dull, for the good demand that appeared earlier has flattened out. On Monday and yesterday the market was nearly nominal, although yesterday a moderate business was done quietly in futures. Late in the day a fair demand for futures developed which may result in business later. Cables continue delayed, interfering with trading. The only interesting feature of the market is the fact that indications point to an easier situation in the shipping-permit question. Nothing definite is known about this, but it is believed that both the American and British governments have come to an understanding regarding the matter and that, as a consequence, consumers that have bought ahead are to get their metal more easily than in the past. It will be the small consumers, accustomed to buying in a small way, that will be hard hit. It is recognized in upper circles that the American tin-plate maker must have tin with which to make cans, and this has helped to bring about an understanding. Arrivals to October 23, inclusive, have been

1910 tons, with 4300 tons afloat. The London market is 5s. under that reported last week, or £247 5s. per ton for spot Straits.

## LEAD

An already weak and declining market has been further unsettled by the announcement last Thursday, October 18, of a reduction by the American Smelting & Refining Co. of ¼c. per lb. in its price, bringing its quotation to 6.50c., New York. This was not a great surprise in view of similar reductions recently and in view of the fact that independents were making efforts to sell under the trust price. This has continued at the new level, and yesterday the outside market was quoted at 6.25c., New York, or 6.12½c., St. Louis, for early delivery. The market may be quoted today at 6.40c., New York, for prompt; 6.25c., New York, for October and November; and 6c., New York, for December delivery. Buyers are ordering only what they need and what they can get hold of quickly. It is believed the bottom has been nearly reached. An interesting instance is that, in the last week, fair amounts of lead in transit have been sold, but they did not command a premium as is usually the case.

## ZINC

The situation is discouraging and in some respects mysterious. Demand now is almost negligible, but a year ago, with the United States not yet in the War, the Allies were buying large amounts of zinc for their needs of the following year and American brass-makers were heavy purchasers for the filling of shell-contracts for the Allies. Now, with the United States in the War, and with its demands for ammunition for its own use expected to be large, orders for zinc are few and far between. Added to this is an inconsequential demand from galvanizers. The entire market is stagnant, with sales of small consequence so far as concerns the establishing of quotations. The nominal price for prime Western is 8c., St. Louis, or 8.25c., New York, for early delivery, with offerings reported at 7.87½c., St. Louis. It is probable that desirable inquiries would bring out a concession from 8c., St. Louis. For later positions from ¾ to ¼c. per lb. higher is asked.

## ANTIMONY

In a lifeless market the quotation for Chinese and Japanese grades has declined to 14.75c., New York, duty paid, for early delivery, but sales are of small proportions.

## ALUMINUM

The quotation for No. 1 virgin metal, 98 to 99% pure, is unchanged at 38 to 40c. per lb., New York, with demand of small proportions.

## ORES

Tungsten: The market is only fairly active, with quotations unchanged at \$23 to \$26 per unit in 60% concentrate. About 100 tons of scheelite is said to have been sold at \$26 per unit, the prevailing quotation. Ferro-tungsten is quoted at \$2.35 to \$2.50 per lb. of contained tungsten.

Molybdenum and antimony: The market is unchanged. Fair sales of molybdenite are reported at \$2.20 per lb. of MoS<sub>2</sub> in 90% concentrate. There is nothing to report in antimony ore.

THE COMPOSITE-METAL PRICE is based on current selling-prices of each of the common metals (spelter, lead, electrolytic copper, and tin) multiplied by the ratio of average consumption, added together and reduced to one pound. The proportions of the metals in the order named are 2.5, 4, 3, and 0.5. The composite price October 24 was 14.2387c. per lb., as compared with 20.0562c. in February.

# INDUSTRIAL PROGRESS

## WET-CRUSHING BALL-MILLS

By F. E. MARCY

The ball-mill, introduced many years ago as a grinding machine, is today the most extensively used in the manufacture of cement, for which it treats thousands of tons of lime-rock and clinker daily, yet it has only recently been extensively used in crushing ores, partly because of its production of slime; partly because mill operators have an impression that it wastes much costly steel; and partly because manufacturers have failed to design and present a suitable ball-mill for wet crushing. I desire first to describe briefly the general action of the ordinary tube and short-mills using either balls or pebbles. I assume that the mills are operated at the proper speed, just under that producing centrifugal 'cling', and that the pulp is of proper consistence; in other words, the usual conditions of good practice. Whether the mills are operated dry or wet makes a great difference in the resultant classification of material. In dry crushing, the larger portion of the fine will be found on the periphery, the reason being that, as the ground material falls in the course of revolution, the larger particles roll a greater distance than the fine, as, in the discharge of a mine-car over a dump, the larger pieces roll to the lower edge of the dump, while the fine remains close to the track. Although partly counteracted by other factors, such as centrifugal action and the agitation of the material, this tendency of the fine remains. It is shown in the Schmidt mills, both the long pebble-mill and the large 'Kominutos' or ball-mill discharging at the periphery. As soon as the balls or pebbles strike a piece of ore, many sizes of particles are produced, including fine and slime, and the classification of these different sizes has no appreciable advantages. To remove the fine and slime as fast as produced is what is desired. In wet crushing the segregation of the fine is less marked and this general condition does not hold true, for as the pulp and water are carried up the fine goes with the water, so that a larger portion of the fine will be found toward the centre and the lower side. In wet crushing, however, much material is 'short circuited' or carried toward the discharge end of the mill by surface currents, and consequently discharged with the fine pulp, thus increasing the oversize product. Consequently, with short mills, of whatever geometric shape, the product is of great variation in size, and much coarse and undesirable material escapes during its operation. In the practical operation of all centre-discharge mills upon a mixed charge, the travel of the charge through the mill is accomplished by replacement; that is, the fresh material going into

the mill displaces the ground material. The rate of speed in this process determines the rate of grinding. There is practically no migration of fine over the coarse, other than that caused by the difference in gravity of the particles themselves. As already observed, the lighter material tends to be short circuited by surface currents, and to remain in the centre of the mill and be carried out with the water; but, in general, there is no appreciable migration of the fine over the coarse. The addition of water will cause the slime to be slightly reduced, but in doing so the oversize particles are greatly increased, so that the net results are not particularly different whether the mills are operated with an excessive amount of water or with a fairly thick pulp. My observation with ordinary wet-crushing mills, of whatever kind, is that where the pulp discharge is practically level with that of the incoming

THE MARCY BALL-MILL.

flow of the feed, there is no stimulating force that causes the fine to migrate faster than the coarse, other than that of the use of a large volume of water; and this produces oversize product. When the pulp in the mill is thickened, or the consistence reduced, greater difficulty is experienced in maintaining a uniform product. The viscosity of the mass, the slow velocity through the mill, tend to keep all classes and kinds of material together. If low consistence prevail, coarse material discharges from the mill. In an 8-ft. mill handling 125 tons per day of 1.5 pulp-consistence, the velocity of this pulp through the mill would be about 6 in. per minute, allowing for the openings between the pebbles, and assuming the mill to be filled to the centre. If the mill is smaller, or tapered, then this velocity increases, with the result of yielding coarser particles in the discharge.

In all classes of pebble-mills, when crushing dry, the larger portion of the fine is near the periphery and should discharge there if non-sliming is required. This condition does not hold good in any considerable degree with a conglomerated mass

due to the introduction of water in wet-crushing mills. Again, in the operation of all classes of pebble-mills there is a vertical classification of the mineral from the gangue; that is, the mineral being heavier is carried lower or next to the periphery and consequently ground into undesirable product. This has been pointed out by Robert H. Richards, who says on the subject: "Tube-mills discharging their pulverized product through the axle or trunnion at the end operate as follows: the removal of the pulp is by the sifting motion of the water something like a tank-overflow. From this it follows that the product is much like the overflow of a classifier and in consequence is a classified product; that is, the coarser quartz, which may be 1 mm. for sake of example, will be accompanied by the soft heavier mineral of a much smaller size so as to be equal settling with the quartz. In other words, the 1-mm. chalcopryite will wait in the mill until it is broken fine enough to be equal settling with the 1-mm. quartz. This seriously interferes with the gravity separation of the minerals, making much slime and failing to give up the 1-mm. chalcopryite which would be the easiest for the concentrating machine to save. Any ball-mill that discharges its product at or near the periphery will make a gain in this respect, taking out much more of the heavy mineral in the larger sizes better fitted for gravity separation."

From the above we learn, concerning all classes of wet-crushing mills, of whatever shape or length, using pebbles or balls, where the discharge is at the centre, that there is: (1) a great waste of power due to the agitation of a conglomerate and viscous mass; (2) a great variation in the size of the product; and (3) a detrimental classification and sliming of the material, as pointed out by Dr. Richards. To remove these three undesirable features, I have designed a ball-mill which shows a product of minimum size; an increase in capacity; a low horse-power per mesh-ton; an equal chance for all products, either gangue or mineral, discharging from the mill; and a stimulating action on the fine as it is produced. After building a number of these mills, I adopted a size 4 ft. in diameter and 26 in. long inside the liners, with the use of balls for crushing, pebbles not being considered on account of their light weight and first cost. The pulp is delivered to the mill in the ordinary way. The liners are made in sections suitable to pass through the man-hole, and fitted with the minimum number of bolts, the use of larger and fewer bolts being preferred, in order to avoid leaks. The circumferential liners are of the standard Krupp type; that is, they are laid like shingles and with the upper holes slotted. Liners can be easily removed without any wedging caused by material getting in between them. The discharge-end of the mill is fitted with a grate filling the entire cross-section, and dividing the mill into two compartments, for grinding and lifting respectively. This grate is made in segments, each segment made up of grizzly-bar sections securely bolted together, and the whole being held in place against the radial ribs or lifters by bolts passing through the head of the mill. These ribs or lifters are from 3 to 15 in. wide, according to the service required.

In the operation of the mill the integrity of the water-line is maintained by the action of the lifters, which have the effect of a pump. In other words, as the material is ground out it passes the grate and from there it is discharged through the trunnion. The pulp-line and the water entering the mill with the feed have a difference in head between the feed and the point of discharge through the grate, and consequently a sluicing action of the water, which quickly carries the fine and slime through. This rids the mill of the slushy mass and causes the fine to migrate faster than the coarse particles. I have successfully made a steel grate having an opening of  $\frac{1}{16}$  in. Thus I am able to get a -12-mesh product which carries approximately 5% on 20 mesh. This mill takes a feed as great as 3 in. diameter and reduces it to  $\frac{1}{4}$ ,  $\frac{1}{8}$ , or  $\frac{1}{16}$  in.

opening, as may be required. The energy available for crushing by steel balls in a ball-mill is from three to four times that of flints, other conditions remaining equal. With the lowering of the pulp or water-level in the mill, leaving the other conditions equal, the pulp-resistance is of less effect and each crushing unit is enabled to deliver its energy with less friction-loss. While the ratio between steel and flints is somewhat reduced, the capacity of the mill is increased. Here are the limitations of flint pebbles: they do not stand up under the falling conditions without the retardation of the pulp, but crack and break up, absorbing energy, reducing effective capacity, and increasing pebble-costs.

In operating a mill such as I have described, in which the pulp-line is below that of the centre-discharge of the mill, it is not possible to use pebbles even if it were thought advisable to do so, for as the mill revolves there is no cushion or landing place for the pebbles that are carried over by the revolution, and consequently they are broken up and rendered useless. Even in the 4-ft. mill it was found that the pebbles broke readily; and again, I have seen pebbles badly broken in a 5-ft. mill, arranged with a device to lower the pulp-line below the discharge; in fact, I have seen tons of pebbles broken by being thrown against each other. Cast-iron balls, if not carefully made, will break. It may be asked, why use such tremendous weights when lighter weights will do the work and produce less slime? A practical answer is, that slime in a cylindrical or conical mill is not caused by the weight alone, but is increased by the time during which it remains in the mill. Short mills with steel balls, having a sluicing action on the fine and slime caused by the addition of water, will produce less total slime than ordinary mills in which the material is allowed to remain a long time. Heavy vertical loads of pebbles or balls do not necessarily produce slime. Large-diameter pebble-mills may produce less slime than small-diameter mills, as other conditions such as length, amount of feed, the number of pebbles or crushing surfaces, all are factors in fine crushing. What is desired is a means to remove the fine sand from the mill as fast as made. In all classes of pebble-mills, my observation is that the length of time the pulp is in the mill has more to do with the sliming than the weight of the crushing medium.

Ball-mills are particularly adapted to handle coarse products: with small installations the product of the crushers; with larger installations that of the secondary crushers. From 1 to 3½-in. feed is good material for a ball-mill.

For crushing finer than 10 mesh we use a screen for the returning of the over-size, then we are able to secure a non-selective product of 10, 20, 30, 40, or 80 mesh. By non-selective we mean that the mineral and the gangue have an equal chance to discharge from the mill. This applies to the screen as well. The benefit derived from such crushing has been pointed out by Richards elsewhere in this article. For flotation, amalgamation, or cyaniding, where finer crushing is necessary, we use mechanical classifiers for the separation of the sand from the fine. It has been found highly desirable and efficient to return the sand with the coarse feed, and the greatest efficiency in crushing is obtained in this way. No pebble-mill or tube-mill is necessary to follow the Marcy mill, as with a mechanical classifier we can crush the ore all to pass 100 mesh, if so desired. In these days, when flotation has assumed so much importance, a mill can be designed and successfully operated, comprising the crusher, the Marcy mill, and flotation machinery, eliminating elevators, rolls, trommels, and expensive buildings. High efficiency, low first cost, is the result that is being obtained by the use of these mills.

The CLEVELAND CRANE & ENGINEERING Co. of Wickliffe, Ohio, continues the publication of its clever little magazinette of humorous stories and anecdotes. The latest is Vol. 8, No. 1, which tells the story of Crane's New Contract when somebody

was home attending to business in vacation-time. The Potato Beetle also has a wise observation, and there are other amusing episodes related to put prospective buyers into a good humor before they get down to brass-tacks and order a crane.

## FIVE-INCH HOLES WITH HAMMER-DRILLS

By H. L. HICKS

\*The reconstruction and enlargement of three dams at Big Creek, Fresno county, California, to provide additional storage capacity is marked by a method of anchoring the new concrete to the original reinforced-concrete structure of dam 2, which required drilling a large number of shallow large-diameter holes. The construction work is being conducted by the northern division of the Southern California Edison Co., whose chief engineer, R. C. Starr, devised a plan of using 6-ft. lengths of 30-lb. rail as ties, setting them vertically into the stepped back of the existing dam. This necessitated the drilling, at close intervals, of 5-in. holes 3 ft. deep. In fact, the practical success of the system was dependent upon the possibility of drilling with rapidity and at reasonable cost the large number of holes required. Owing to the unhandy situation of the holes to be drilled, it was out of the question to use the heavy tripod-mounted piston-drills usually employed for putting down large-diameter holes. E. L. Fox, superintendent in charge of the drilling, placed his faith in the ability of unmounted hammer-drills to carry out the work, although nearly all the drill manufacturers were of the opinion that it would not be possible to handle bits as large as 5 in. diameter because of the large number of very hard boulders that would be encountered embedded in the concrete. After experimenting with various bits and different machines, Mr. Fox finally selected Leyner-Ingersoll drills for this heavy duty, they having shown from 30 to 40% greater speed than others. Eight drills are in use, of the type ordinarily employed in tunnel-driving on a column or bar mounting. The drills have been fitted for this work with special handles and are operated by two men as hand-hammer drills. Standard 1½-in. solid round steel is used with 5-in. bits. The Leyner water-feeding device has been dispensed with and the holes are drilled dry, the cuttings being cleaned out by means of an auxiliary blow-pipe. The average drilling time for a 3-ft. hole is 20 minutes. The duty on the drills is severe, and to relieve the strain as much as possible a Leyner sharpener fitted with special dies to handle the large bits, was installed. Absolute gauge perfection secured in this way relieves the drill-rotation mechanism of excessive wear and has largely eliminated loss of time due to stuck steels. When all the holes have been drilled the lengths of rail will be grouted in and the forms set for pouring the new concrete.

## PATCHING A CONCRETE ROAD

By H. B. BUSHNELL

While Section 'D' of the DeKalb county, Illinois, concrete State aid highway between DeKalb and Waterman was being built last fall, a teamster drove his wagon over about 100 ft. of the pavement that was not more than 6 or 8 hours old. Ruts were formed from 1 to 2½ in. deep and the concrete was shattered for 2 or 3 in. on either side. A number of deep holes also were made by the horses' hoofs. The damage was not discovered until the concrete had thoroughly set and it appeared that the only way to remedy the condition was to tear out and re-build approximately 60 ft. of the road. The contractor, however, requested that he be given an opportunity to patch the damaged portions and if such work proved unsatisfactory, he agreed that he would later re-build it. The opportunity of

repairing the road was granted, and the contractor did the work himself early this spring, spending three weeks in cutting out and repairing the ruts and holes. The results he secured were all that could be desired. It is hard at the present time to detect some of these patches even when standing directly over the repaired spots. An interesting feature of the way in which the work was done was that to keep his tools sharp the contractor rigged up a small emery wheel on a Ford automobile and thus kept continually on the job without loss of time.

## STRANGE FREAK OF DYNAMITE

By J. B. STONEKING

Recently, while sinking a shaft on the property of the Land Lead Mining Co. at Joplin, Missouri, a peculiar incident occurred which illustrates the enormous power of dynamite, the peculiarities of rock-cleavage and breaking-lines, and the effect of air-resistance on a rapidly whirling body. A 5½-in. well-drill prospect-hole had been sunk previously to find the orebodies, and a shaft 5 by 7 ft. was begun, using the well-drill hole as a centre line. When the bottom of the shaft was 75 ft. below the surface in hard limestone, the incident occurred. The cut-holes, sometimes called 'sump' holes, eight in number and 5 ft. deep, were arranged to blast out the centre-cut to relieve the burden on the rib or squaring-up holes to be drilled later. These eight cut-holes were each loaded with four cartridges of 1½ by 8-in. Red Cross gelatine of 40% strength and a No. 6 electric blasting-cap, making a total of 32 cartridges. The eight holes were fired simultaneously with an electric blasting-machine, and the force of the blast threw a large boulder from the bottom to a height 100 ft. above the top of the shaft. The boulder fell 50 ft. away from the centre of the shaft on top of the mine-car track leading to the dump, breaking and bending it out of shape. This boulder when measured was 1½ ft. thick, 3 ft. wide, and 4 ft. 6 in. long, but was somewhat irregular in shape and was estimated to contain about 16 cu. ft. The weight of this class of stone is 165 lb. per cu. ft., which would make the total weight of the boulder approximately 2600 lb. As the height of the lift was 175 ft., the work done represents the expenditure of 455,000 ft. lb. of energy, or 17,344 ft. lb. per cartridge of dynamite. This is not by any means the total energy in the dynamite, for such important items as the energy required to disrupt the cohesion of the rock, the enormous air-resistance against the hurling of this immense boulder, are entirely unknown and are not computable, but they show the vast amount of energy contained in dynamite for the performance of useful work.

Ordinarily, when subjected to a violent rending and disruptive force, rock will break at the weakest point, and often, in some classes of work, holes are drilled along the line where it is desired that the rock should break, so as to weaken it along the projected line. A peculiar feature of this blast is that, although there was a large hole, 5½ in. diameter, in the centre, the rock did not disrupt nor break along an imaginary line drawn through this centre hole, which might be theoretically taken as the weakest part. This boulder came out and landed with the well-drill hole intact through the 18 in. of thickness, and not even a crack was found radiating outward from the centre. Another peculiar feature of this freak performance was that the boulder rose to the top of the flight without twisting or whirling, but at the beginning of its descent it began whirling rapidly, and this action caused it to curve outward and land 50 ft. away from the shaft. Since the boulder did not strike the sides of the shaft in the upward course, the line must have been practically perpendicular, or, at the maximum, at a very slight angle from the vertical. Taking the maximum angle that would allow the

\*'Engineering News Record'.

boulder to clear the collar of the shaft without touching, the point at which it would have struck the ground should be 20 ft. from the shaft. The influence of the air on a rapidly whirling body is here strikingly shown, for the difference between 20 and 50 ft. gives 30 ft. as the horizontal effect of the curvature in the descending flight. Many strange features, of which this incident is an example, occur when enormous forces are loosed, and when they work opposed to natural forces and subject to the laws of physics.

## CHEAPER PROTECTION FOR ELECTRICAL DEVICES

Suppose that a short circuit should take place on a power-line and that the machines in the station which send the current should happen to be unprotected. Serious damage almost certainly would result; lights might be out for hours, and fans, motors, heating-devices, and vacuum-cleaners would cease their operation. Of course, this rarely happens, for protection is usually adequate. Circuits are safe-guarded automatically by electrically operated devices which, opening under unusual stress, cut off the circuit at a sign of danger. As a rule, these automatic devices receive the power which causes them to open the circuit from current transformers which change the current from a large to a small quantity and keep the dangerous voltage or high-pressure away from the automatic devices. The transformers also assist the measuring instruments in their duties as indicators and recorders of the current or power on the line. When thus used the transformers must possess high accuracy and hence are quite expensive. Today, if measuring and recording are unnecessary, as is true in many cases, a small tripping transformer as shown in the accompanying illustration, designed recently by the General Electric Co., may be used in connection with the automatic device. This eliminates paying the higher price for a more accurate transformer and, since the new device is accurate enough for tripping purposes, it offers a similar advantage, that is, it results in a simpler, cheaper, and safer arrangement.

Although small and inexpensive, the new invention offers a convenient and satisfactory method of safe-guarding valuable apparatus.

## DEISTER MACHINE FIRM WINS CASE ON PATENTS

Judge A. B. Anderson, of the U. S. District Court at Indianapolis, after several days' trial, recently decided the case of the Deister Machine Co. v. the Deister Concentrator Co. against the defendant. He held that the letters patent of the Plat-O concentrating tables manufactured by the plaintiff company were valid and that the defendant company had infringed the plaintiff's letters patent in its manufacture and sale of its Deister-Overstrom table upon which it used the compound wedge or plateau. He enjoined the defendant from further making and selling the infringing table. Barrett, Morris, and Hoffman, and Darwin S. Wolcott, of Pittsburgh, were attorneys for the plaintiff, and Hosea, Knight, and Phares, of Cincinnati, and Walter L. Burns, of Fort Wayne, represented the defendant company.

FRASER & CHALMERS OF CANADA, LTD., recommend Ross box-pumps for handling muddy water, pulp, and tailing against heads up to 200 ft. These are provided with hard cast-iron and manganese-steel parts. The Ross box-pump has a low cost of up-keep and requires little attendance. The high efficiency is on a par with high-grade balanced-impeller volute pumps. For heads up to 100 ft., the Ross pump in its single-unit form can be used. For higher heads the multi-unit arrangement is recommended. The distinguishing features of the Ross box-

pump are low peripheral speeds, balanced impeller, large stiff shafts to eliminate vibration, ample bearings, ease of operation, and renewal of parts through one door without disconnecting piping, and the use of the most suitable metals. All parts are standardized and machined to gauge and are therefore interchangeable.

## KANSAS SPECIFIES ROLLER-METHOD

Through the courtesy of W. S. Gearhart, State highway engineer of Kansas, we publish the following specifications regarding the roller-method of finishing which has been adopted by the Kansas Highway Commission: After the surface of the concrete pavement has been struck off to the proper cross-section, it shall be rolled with a light hollow sheet-steel roller, about six ft. long and 10 in. diameter, to which a bail is attached, carrying a long handle. The roller shall weigh approximately 70 lb., and the handle shall be of sufficient length to reach entirely across the pavement. The roller shall be moved transversely across the surface of the pavement and rolling shall continue at intervals until little or no free water is squeezed from the concrete. After rolling, and just previous to the concrete obtaining its initial set, the surface shall be finished by drawing a belt over it with a combined longitudinal and cross-wise motion, in order to produce a uniform surface of a gritty texture, free from depressions and inequalities of any kind. Great care shall be taken to prevent rubbing hollow places in the surface. Short-handled wood-floats may be used as a substitute for the belt, only upon written authorization of the engineer, in which case the finishing shall be carried on from a suitable bridge, no part of which shall come in contact with the concrete. Long-handled wood-floats shall not be used.

## ONLY THE CEMENT-GUN COULD DO IT

\*In the sea-wall of Governor's Island, in New York harbor, were many thousand feet of joints between the stones from which the mortar had disappeared, leaving open seams 1 to 1½ in. wide and from 3 in. to 3 ft. deep, and for the safety of the wall it was necessary that the mortar or its equivalent should be replaced. Hand-work could not be relied upon for placing mortar to depths exceeding 6 in., and accordingly the cement-gun was employed. The outfit comprised, besides the gun, a portable gasoline-driven compressor, on which was mounted also a Gould pyramid pump. The entire force employed comprised a compressor runner, a gun-man, five to seven laborers, a horse and cart, and an overseer. The rig, in 25 working days, filled 22,320 ft. of joint, or 900 ft. per day, at a total cost of \$2913, or a trifle under 13c. per foot. Henry N. Babcock, U. S. Assistant Engineer, estimates this cost to have been 10 to 15% greater than it would have been in a more accessible location. The average depth of the joints was 12 to 15 in., and, so far as a number of tests could determine, all joints were filled to their full depth with compact and durable mortar.

The E. I. DU PONT DE NEMOURS, and its associated companies, have just issued a handy little booklet which contains a list of all the products manufactured by these concerns, including the Du Pont Chemical Works, Du Pont Fabrikoid Co., The Arlington Co., and Harrisons, Inc. This booklet does not indicate who uses the products or how they are used, as does the Du Pont Products Book, but it will prove of interest and value to many mercantile and industrial men. It is small enough to fit in the pocket. It will be sent upon application to the Du Pont office at Wilmington, Delaware.

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.

Entered at the San Francisco post-office as second-class matter. Cable address: Pertueola.

Branch Offices—Chicago, 600 Fisher Bldg.; New York, 3514 Woolworth Bldg.; London, 724 Salisbury House, E.C.

Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries in postal union, 25s. or \$6.

## World's Largest Ball-Mill Plant Driven by G-E Motors

This notable installation of forty-eight electrically driven Marcy Mills at the Inspiration Consolidated Copper Company, Miami, Arizona, must operate 24 hours a day for long periods.

For this, the largest installation of its kind in the world, G-E 225 h.p. induction motors were selected. These motors have high efficiency—so important for long period operation—and ample starting torque.

Practically standard construction was selected for these motors, and the selection has been justified during the last two years by an operating record which has been successful in every respect and the basis for large repeat orders.

Hundreds of grinding mills are driven by G-E motors. Among those using these motors are the Calumet & Hecla Mining Company, the Anaconda Copper Mining Company and others equally well known.

# EDITORIAL

**A**MONG the peaceful advances of man we may record the completion of the Australian transcontinental railway, the last link between Kalgoorlie, in Western Australia, and Port Augusta, in South Australia, having been closed. Now there is continuous rail connection between all the States of the Commonwealth from Perth to Brisbane. The last portion of the line—1060 miles—was started in 1912; the completion of it was delayed by natural difficulties and by an under-estimate of cost. A sparsely inhabited and unproductive region had to be traversed, so that materials of construction and food had to be hauled as much as 900 miles. Labor strikes proved another hindrance to speedy work. The journey from Brisbane to Perth, 3467 miles, or 215 miles more than the distance between New York and San Francisco, will take five days.

**T**HE origin of saltpetre has been a subject of discussion by scientists for many decades. In this issue we publish a suggestive article by Mr. Hoyt S. Gale, of the U. S. Geological Survey, in which he attributes the formation of natural nitrate salts to the action of nitrogen-fixing bacteria. There is much warrant for this explanation of the phenomenon. A French biologist many years ago wrote an elaborate treatise on the Chilean deposits, in which he advanced the theory now advocated by Mr. Gale. It is certainly plausible in view of the extraordinary nitrogen-fixing function of the azotobacteria that are found in all soils containing humus. The presence of abundant organic matter, the absence of acidity, and the need of magnesia and of certain chlorides are essential features, however, and such conditions do not always exist on the exposed cliffs where nitrates are sometimes discovered. The bacterial theory is sound, and fully accounts for most of the small deposits known in this country, but evidently other principles are operative, and in places may be important.

**W**E draw attention to our New York correspondent's remarks, under 'Eastern Metal Market,' concerning the selling of copper. His statement is confirmed by information coming from other sources. The market for copper has passed into the hands of a so-called Producers Committee consisting of representatives of the United Metals Selling Company, American Smelting &

Refining Company, the Phelps-Dodge Corporation, and the Calumet & Hecla group. This semi-official body calls for monthly reports from producers and consumers; it is obtaining the most complete information concerning the industry. No orders for shipment of refined copper can receive attention unless countersigned by this committee. Selling agencies have been asked to show orders on their books, the amount of copper sold and the names of their customers, together with the scheduled date of delivery. Mr. Edwards Mosehauer, of the United Metals Selling Company, is in charge of the Producers Committee's office at 61 Broadway, New York. It is presumed that all this is being done by authority from Washington, but we would like to be assured that such is the fact. The small producer and the small consumer may be forgiven for feeling apprehensive of this organization, which concentrates so much power and information into the hands of a few big corporations.

**E**FFORTS now being made by representatives of the Mexican government to raise money at Washington in order to buy corn for the famishing peons are likely to have good results in more than one direction. It is reported that the Administration will not listen to the request unless Mexico shall align herself with the Allies, but this is a crude way of stating the case; what is meant is that we have no food to spare except for our Allies, and that therefore Mexico will knock in vain at our granary until she comes as a partner in our great enterprise. General Obregon asserts that four or five million Mexicans are on the edge of starvation, and he may not have explained that lack of food will drive the miserable victims of misrule into a new revolt against Carranza's government. It is suggested that Secretary Lansing will tell the Mexican envoy that nothing can be done until Mexico breaks with Germany, and puts an end to the propaganda of the Enemy not only in Mexico City but along the border. Of course, it is not in the fitness of things that we should go out of our way to feed a country that chooses to support the German at this time, but we see something bigger to be done, namely, to win good-will and thereby promote friendly relations with the people of Mexico. If the United States were to supply corn, or other food, for the starving peons, and if the distribution of such food were done by the hands of Americans, under

the direction of the Food Administration, we would have a chance to prove to the Mexican people that the gringo is a good fellow, after all, and that he was willing to help them at a time when Carranza and his marauding generals were helpless to prevent famine. This would lead to the establishment of such a friendly understanding as would go far to settle the Mexican problem.

**E**LSEWHERE we refer to the importance of the coalfields of northern France now held by the invader. Part of this industrial region has been regained from the Enemy, for it has been reported that 10% of the producing capacity of the Lens district is in the hands of the French. Of course, the invaders have pillaged and destroyed the area under their control and the equipment of the mines has been wrecked with Hunnish thoroughness. The system of mining practised in this coalfield is the long-wall, not the pillar method. It is likely that the Germans will have blasted the linings of the shafts so as to admit water and quicksand, the sinking having been done in part by the freezing process. Some of our readers are aware that a plan has been set afoot to assist our French allies by organizing a group of American mining engineers to aid in the re-opening of these coalfields. The work has been taken in hand by a committee appointed by the Mining and Metallurgical Society; it is headed by Mr. C. R. Corning and includes Messrs. A. R. Ledoux, R. V. Norris, E. T. Conner, and S. C. Thomson. Conferences have been held with the French Ambassador at Washington and with the French Commission now in this country. We wish our friends every success in this useful work; the abilities of our profession could not be applied to better advantage.

**N**EWs comes from Johannesburg that the Anglo-American Corporation has been organized at Johannesburg with a capital of \$5,000,000, for the purpose of tendering for the mining areas to be placed on offer by the government of the Transvaal. The directorate includes Mr. W. L. Honnold, a distinguished American mining engineer, formerly identified with the Consolidated Mines Selection and Brakpan Mining companies; also Mr. Charles H. Sabin, president of the Guaranty Trust of New York, and Mr. H. C. Hull, formerly Minister of Finance in the South African government. The chairman is Mr. Ernest Oppenheimer, of Kimberley. Whether this new corporation is to issue a loan in America in behalf of the Union government or to engage in mining, we do not know. Any active competition in tendering for the exploitation of Government areas on the Rand has been killed, in large measure, by an agreement between the leading 'houses' controlling the major operations of South African mining, so that these financial powers will not compete with each other. The question arises, will General Botha and his administration regard this combination in restraint of trade with a favorable eye? Unfortunately the interest shown by the Lewisohns, through Mr. W. W. Mein, early in 1916 has come to nothing and the American participation in Rand

mining has, as a Cornishman would say, "just naturally petered out."

**W**E are informed that the directors of the American Institute of Mining Engineers have appointed Mr. E. K. Judd, assistant professor of mining in Columbia University, to be editor of the bulletins and transactions of the society. This is a step much to be commended. The present secretary of the Institute, as our readers know, is an able executive, but his multifarious duties have rendered it impracticable for him to do the work of an editor, so that the publications of the Institute have exhibited a lack of revision, forcing a contrast with the work of the old régime, under which the editing was done so thoroughly by Dr. Raymond, leaving much of the executive work to his assistants, notably to Mr. Theodore Dwight and Dr. Joseph Struthers. We have deplored the un-edited texts that have been published by the Institute, because it seemed to us that a bad example was being set to the profession; therefore we record Mr. Judd's appointment with keen pleasure. His early editorial experience was shared with the present writer, in another place; so that we are in a position to know something of his aptitude for such work. He is editor of the 'Columbia School of Mines Quarterly'; more recently he has acted as editor for the Mining and Metallurgical Society, but that was not a test of his ability, because the junior organization does not publish much and because its chief contributors have been gentlemen not without experience in technical writing. We wish Mr. Judd every success at his new post.

## Miners Advance!

A telegram from Major O. B. Perry informs us that the Engineer Corps of the United States Army has been authorized to raise, by voluntary enlistment, a special mining regiment to consist of six companies of 250 men each and to be known as the 27th Engineers National Army. This regiment is now being recruited, the first company having been formed and placed in training at Camp Meade, Maryland. The regiment is to be composed entirely of picked men representing various mining districts throughout the country and comprising all the trades and occupations incident to mining. Each company will contain representatives of every branch of mining work so that it can operate as a unit. The men most wanted are experienced miners, both hand and machine drillers, shovelers, trammers, timber-men, track-layers, pump-men, blacksmiths, tool-sharpeners, electricians, machinists, carpenters, surveyors, time-keepers, cooks, shift-bosses, mine-foremen, and top-men. That is the order in which they were named to us. The work to be done is purely military in character, and is what is known as 'first line' work; it consists in the preparation of underground shelters for the fighting troops and the placing of explosive mines. Such work requires a high degree of skill in rapid tunneling and involves the han-

dling of all sorts of material, from clay and chalk to the hardest rock. In addition to the regular engineering equipment, each company will be provided with special tools, such as tunneling and boring machines, drills, compressors, hoists, and lighting sets. Although the chief function of the 27th regiment will be underground mining, the men will be trained to fight as well as to dig; an engineer officer of the Regular Army will be placed in command, the other officers being selected mainly from the mining engineers that have already volunteered and undergone training. Major Perry and Captain W. H. Landers, two mining engineers well known in the West, have charge of the enlistment. Applications should be addressed to the Commanding Officer, 27th Regiment, Office of the Chief Engineers, Washington.

This announcement should meet with a ready response from the younger members of the profession and from the men that are working with them in the mines. It is a gratifying compliment to the mining fraternity and offers an exceptional opportunity to perform patriotic service under favorable conditions. This will not be the first time that a regiment of miners has played a noteworthy part in history. During the Indian mutiny, in 1857, when the residency at Lucknow was defended by the troops under Sir Henry Lawrence, the regiment that held the fort was the 32nd Duke of Cornwall Light Infantry, known as the Cornish regiment, because it was recruited in the old mining county of Cornwall. They made a victorious stand, largely because they were able to countermine the sapping of the Sepoys. As the chronicler says, "they took kindly to mining." We shall be surprised if some of the American descendants of those Cornishmen do not find a way into the 27th Engineers of the National Army. Brothers of the pick, this is your chance. Assert your manhood. You have been the pioneers of industry in the waste places of the earth. Now it is your privilege to save civilization from the onslaught of organized hell! Enroll yourselves not only to keep the world safe for democracy but to keep your hearths and homes safe from piracy on land and sea. Miners, follow on!

## The Spoils of War

Recent discussion of the terms of peace has overlooked an item of some importance. Among the objects of the German invasion of France and among the reasons for the tenacious holding of the invaded territory we cite mineral resources of the greatest interest to the mining engineer. Most of our readers are aware of this fact without knowing the details. Among the public statements of German purpose none is more representative than the manifesto of the six industrial associations dated March 20, 1915, and presented to the German chancellor in May of that year. The six societies signatory to this document represent the non-socialistic classes in the German empire; they include the manufacturers of Saxony and the peasant proprietors of Württemberg; they repre-

sent the economic interests of Germany. In this manifesto emphasis is laid on the necessity for holding Lorraine, "including the fortifications of Longwy and Verdun." Iron ore is not specified, it being taken for granted that the implication would be understood, for the next paragraph reads: "The possession of large supplies of coal and, in particular, of coal rich in bitumen, which is found in great quantities in the basin of northern France, is decisive, for the result of the War, at least to as great an extent as the iron ore." A glance at a map showing the distribution of coal in France makes clear the importance of the northern region. According to the committee appointed by the International Geological Congress of 1910 to report on the coal resources of the world, Germany has 409,975 million tons of bituminous coal in reserve, whereas France has 12,680 million tons; of which 9000 million tons are in the northern coalfields of the Valenciennes and Pas de Calais basins. In 1912 the mines of the Valenciennes coalfield yielded 26,139,948 tons and employed 123,698 workers. The names of the chief mining centres have been made known by the operations of war; from west to east they are Marles, Lens, Douai, Valenciennes. Thence the coal-seams extend across the northern border into Belgium, where the names eastward again are resonant of war, Charleroi, Chatelet, Namur, Liège, and Visé. Near the last of these mining centres the coalfield leaves Belgium and crosses the border into Westphalia. In Belgium there are two other coalfields, those of Dinant and Campine, but much the most important is the one that follows the valley of the Meuse from Namur to Visé. It is estimated that a reserve of 3000 million tons of coal remains in this Belgian coalfield. Here we have one reason for the German invasion and occupation; but the intention to seize the iron resources of France was a more important object. The deposits of the famous 'minette' ore extend into Luxemburg, Lorraine, Belgium, and France. Germany is in temporary possession of the whole of this mineral wealth. The ore is low-grade, namely, 36%, but the deposit is of such big dimensions that it can be mined cheaply. The ore-zone is 8 miles wide and 40 miles long, and as much as 60 feet thick. In France the principal orebodies are in the Nancy and Longwy-Briey basins. What the iron deposits of Lorraine and those of the adjoining part of France covering the Briey basin mean to either Germany or France is shown by the statistics of production in 1913. From Alsace-Lorraine, Germany obtained in that year 21,000,000 tons of iron ore, out of her total production of 28,600,000. In the same year the Briey basin, now occupied by the German invaders, produced 12,700,000 tons out of the total French production of 21,700,000. Thus three-quarters of the iron ore mined in Germany before the War came from the French territory annexed in 1871, and if the lost provinces were regained Germany's output of iron ore would decrease to 7,600,000 tons, while France's would increase to 42,700,000. On the other hand should Germany remain in possession not only of Alsace and Lorraine, but also of the

Briey basin, her output would increase to 41,300,000, while France's would dwindle to 9,000,000 tons. If therefore we consider the coal and the iron resources existing in the French area occupied by the German troops and add to that the iron resources of Lorraine, we find that on the possession of these disputed territories depends the future industrial development of both Germany and France, but more particularly of our gallant Ally.

## Foods, Metals, and Labor

A summary of the economic situation in the United States appearing in the October circular emanating from the National City Bank of New York predicts prosperity throughout the coming year on account of the enormously increased purchasing power possessed by the agricultural population. The farm-values of all foods this season, according to the forecast of the Department of Agriculture, reach the extraordinary total, in round figures, of 21 billions. This is 47% in excess of 1916. On the other hand, products from the farm for this year and 1916 combined are considerably below the output for the preceding biennial period. The shortage is clearly due to the same inability to obtain labor that has curtailed the production of metals. Therefore the outlook for next season is viewed with alarm by many economists. It must be remembered that a continuous increase in the manufacturing population has been observed for decades, and that this movement has been enormously accelerated since the outbreak of hostilities in Europe. For a time the mines did not suffer, and before the War it was noted with interest that farm-products had advanced greatly in price, while the metal-market remained nearly stationary. Now the mines are beginning to feel the shortage of labor. Part of this has been the direct result of enemy propaganda, but part of it also has come from natural causes. The pressure to manufacture the supplies needed on so huge a scale for maintaining our Allies beyond the sea and for equipping our own Army and Navy, has called into existence a manufacturing capacity in excess of anything hitherto witnessed in this country, and altogether out of proportion to the quantity of raw materials issuing from our mines and farms. This is an economic problem of magnitude that must be considered and dealt with wisely or we shall be placed under a strain that may in the end weaken our resistance. From Arizona comes news that the special conciliators representing the President have secured the adherence of the mine-operators to an agreement recognizing the principle of the grievance committees, and establishing a central employment-bureau in order to facilitate the manning of the mines. This is hoped to aid in holding laborers by making it cheaper and easier to find work. It will be interesting to see whether this attempt to overcome the scarcity of workers at the individual properties will have an influence on the district as a whole by attracting a larger

number of men. The outcome may throw light on the possibility of stemming the tide of labor now pouring into manufacturing operations to the detriment of our fundamental producing-power. Without considering problems of industrial management involved in the settlement of the strike at the Arizona mines, the precedent established for meeting the demands of labor unions throughout the West may incidentally involve a wider control of the economic situation.

## The Komspelter Region

A recent visit to the zinc-mining districts on the western flank of the Ozark uplift suggests the need for the coinage of a comprehensive name to cover this most interesting and important region. For a time it was called the Joplin district, because the zinc-lead deposits were traced south-westward from that famous mining centre in Missouri. The exploratory work and mining development of the last two years, however, have proved that ore deposits, more important than those of Joplin, exist in the north-eastern corner of Oklahoma, at Commerce and at Picher, near Miami. The mines are not at Miami, but a few miles north of that budding town, the importance of which has been magnified by a systematic campaign of publicity, including the employment of a professional booster, a gentleman whose rhetorical exuberance may be likened to that of a gusher in the neighboring oilfield of Cushing. We admire the enterprise of the Miami townspeople and regret to seem cold toward their energetic propaganda; but it will be evident to anybody not intoxicated by the local boom that Miami is an unsuitable name. It is already the name of an older and more famous copper district in Arizona. To give the same name to two important mining centres is only to invite confusion detrimental to both. Moreover, the ore-belt extends not only far beyond the Miami district, but outside the State of Oklahoma, otherwise the 'Oklahoma zinc region' would be a suitable name. The programme of the recent Institute meeting used the compound 'Joplin-Miami' to cover the mining industry of this part of the Middle West, but even that will not do, because Joplin is relatively unimportant, save for the fact that it boasts the best hotel within reach of the mine-operators. On the other hand, the principal ore-belt is now being traced northward into Kansas, so that it is impracticable to localize the mining activities by using the name of any two or more towns or of any one or two States. We need a comprehensive name, adequate to cover not only the past productiveness of Joplin and the present output of the Commerce-Picher-Miami groups of mines, but also the future development of the promising area that extends to Waco, in Kansas, and even farther north. Therefore we suggest 'Komspelter.' This links the initials of the three States of Kansas, Oklahoma, and Missouri to the trade name of the metal zinc. We hope that this suggestion will be considered favorably by those whom it may most concern.

## Mill-Tests v. Hand-Sampling

The Editor:

Sir—My attention has been called to an article, under the above caption, by Morton Webber, in your issue of September 29.

Mill-tests have long been used in one way or another as a check on hand-sampling, usually under the assumption that the mill-test, however crude and unscientific, gave correct results and hand-sampling did not. It is true the usual mill-test gives two factors, the value of the ore and the recovery. Mr. Webber, however, limits his mill-test to the point of establishing the value of the crude ore and he attempts to accomplish this object in a crude and round-about manner. "The object"—he informs us—"is to determine the head, recovery, and tailing-loss without reference to metallurgical efficiency." As it is vital to sample the tailing accurately, as part of the calculation to obtain the sampling-error, the simplicity in sampling sand in leaching-vats will illustrate why I favor a small cyanide plant as a sampling-error indicator."

What Mr. Webber really requires is a sampling-plant that will give directly the value of the crude ore and thus check *mill*-sampling against *lot*-sampling, a not uncommon method of procedure. However, instead of hand or mechanical sampling of ore *lots* he introduces a mill with its many sources of error, not the least of which is the actual tailing-loss, and assumes that "If 60% is recovered by the mill and 20% is known by careful assay to be retained in the tailing-pile, the unaccounted difference of 20% represents the sampling-error."

Now to turn down hand-sampling on any such statement or method or assume the 20% difference above as a sampling-error is quite unsound.

There are many sources of metal-loss outside the tailing-pile; in fact, I cannot recall a case where the metal in the tailing plus the metal recovered equaled the metal in the crude ore milled. Nor could I conceive of any accurate test on small lots of ore, based on cleaning up amalgamated plates, in the manner indicated.

Hand-samples can be cut down, pulverized, and assayed with minimum error, and if cut in the mine with due care usually give commercial results. Lot-samples can be carried out similarly, the lots passed through a sampler, and the correct value of the ore determined without mixing in metallurgical errors and the sampling and weighing of various mill-products with their attending discrepancies.

The examples given by Mr. Webber of a low-grade gold deposit in Central America is illuminating; the assumed inerrant mill-test we are told "Disclosed a sampling-error averaging about 40c. on an expected mill-head of \$3.50." No approved system of sampling should be questioned by such a statement or condemned on such a mill-test.

In common with, I believe, most engineers, I have had all my sampling done on a basis of pounds per foot of sample cut and pointed out the importance of this procedure in a paper on mine-sampling, 14 years ago.

PHILIP ARGALL.

Denver, October 19.

## King of Arizona Company

The Editor:

Sir—My attention has just been called to an interview with Mr. D. M. Riordan published in your issue of October 6. The statements therein contained with reference to certain of the directors of the King of Arizona Co. are so far at variance with facts that I am inclined to think you have misquoted Mr. Riordan. If you have not misquoted him, his memory has failed him in the past 18 years and in reminiscence he paints pictures of things that did not exist.

There was never at any time a disagreement among Messrs. Ives, Blaisdell, Riordan, and myself at any meeting of the board. The minutes evidence the fact that the only disagreement that ever occurred at any meeting of the board was between Messrs. Riordan and Smith. That was at a meeting held at Yuma, Arizona, on June 27, 1899, and grew out of a report and recommendation submitted by Blaisdell and adopted as the policy of the company by the votes of Riordan, Blaisdell, Ives, and Randolph. Smith declined to vote and made the following statement, which was spread upon the minutes of the meeting:

"Mr. Riordan is responsible for the opinion of Mr. Blaisdell as reported. Mr. Blaisdell's views as reported were not Mr. Blaisdell's views until today. Lest the stockholders reading these minutes should regard this policy as emanating from Mr. Blaisdell and thereby acquire an improper opinion of Mr. Blaisdell's ability as manager I object to the form of the motion."

This was not a serious matter, but I recall now, as my memory is refreshed by reading the minutes, that Mr. Riordan's feelings seemed unduly wounded by Mr. Smith's criticisms. Riordan was the president of the company, Blaisdell the manager. The policy suggested

by Blaisdell was sound and even if Riordan had influenced him to make the report in the form made, it was not only his privilege to do so, but his duty. However, from that time forward, Mr. Riordan seemed to lose interest in the affairs of the company and only attended one more meeting of the board, which was held on July 21, 1899. At this meeting the only business transacted was a report from me to the effect that I had borrowed for the company \$20,000, giving the terms, etc., all of which is spread upon the minutes. The following resolution concludes the meeting of the board:

"On motion of Mr. Riordan, seconded by Mr. Ives, the action of Mr. Randolph was ratified and approved. On motion of Mr. Ives the meeting then adjourned."

The next meeting of the board was on August 13, 1899. This meeting Mr. Riordan did not attend but sent in his written resignation as president of the company without assigning a reason. Thus ended Mr. Riordan's connection with the company.

Now, if two of the directors of this company were "heeled" as Mr. Riordan puts it, at any meeting of the board, it must have been at the June 27th meeting, and those two directors must have been Riordan and Smith, but if they were "heeled" there was no evidence of the fact at the time.

Riordan's statement in your interview to the effect that there was a combination among the directors "to do up Smith" is utterly false. On March 7, 1899, the King of Arizona Co. entered into a contract with Smith and Blaisdell, as a firm, to build a cyanide plant and do certain other work in and about the mine, for which they were to receive, when completed, a stipulated number of shares of the stock of the company. In view of the fact that these two men were to become large stockholders of the company upon the fulfilment of their contract, they were, simultaneously with the signing of the contract, given each a share of the company's stock and elected members of the board of directors that they might have the fullest knowledge of all transactions of the company. Blaisdell was also made manager of the mine that he might conduct its affairs upon the ground at the same time that he was engaged in erecting the cyanide plant in fulfilment of the contract of Smith and himself. It was of the utmost importance that the work undertaken by Smith and Blaisdell be completed on contract time, for the reason that the company required the proceeds from the plant in order to meet certain deferred payments on the mine. In the progress of this work it became apparent that Smith and Blaisdell would not complete their contract on time or anywhere near it, and it was the opinion of the directors that this work was being purposely delayed by Smith. When still later it became evident that Smith and Blaisdell would not complete their work on contract time, a forfeiture was declared and the company took over the unfinished plant and completed it. At the time it did so, it offered to issue to Smith and Blaisdell shares of the company's stock in the ratio that the work already performed by them bore to the entire contract. Blaisdell

for himself accepted this offer and stock was forthwith issued to him. Smith declined to accept and brought suit against the company. This suit was decided in favor of the company in the trial court at Yuma and was later affirmed by the Supreme Court at Phoenix. Smith appealed to the Supreme Court of the United States and while the case was there pending the matter was compromised and stock issued to Smith in accordance with the compromise agreement. Smith later sued to rescind this latter contract, employing a new firm of lawyers. The firm first employed by Smith sued him attaching the stock, which was later issued to them by order of the court and they drew dividends upon it from the beginning of the dividend period to the time that the mine ceased to operate. So much for S. Morgan Smith's connection with the enterprise.

Your interview makes Mr. Riordan state that Mr. Smith was the principal person who put "real money" into the venture besides himself (Riordan). It is not known to the undersigned just how much money Smith spent upon his contract. Mr. Riordan's investment in the company was \$5000 "real money." The undersigned invested \$10,000 "real money" on the day the mine was optioned, and thereafter procured for the company or invested in its shares from time to time very much larger sums of money. There were nine stockholders each of whom put more "real money" into the property than Mr. Riordan, and some of them very many times more "real money."

The company records here in Tucson and the court records in Yuma and in Phoenix will verify all of the statements herein made, and they are open to inspection by anybody at any time.

EPES RANDOLPH.

Tucson, Arizona, October 25.

## Estimating Ore

The Editor:

Sir—Given an orebody 800 ft. wide, 1600 ft. long, that rises above the surface from 100 ft. on one end to 800 ft. at the other end, all being quartz and exposed; with assays from many parts from zero to \$19 per ton, and with several general samples weighing from 200 to 350 lb., showing from \$5 to \$8; mill-tests on 1½ tons, 3 tons, 10 tons, 4 tons, and 40 tons, averaging better than \$5 gold per ton saved on the plates; I wish to know whether more than two well-known experienced engineers can agree upon the proper methods to sample this with a view to purchase. The above is an actual orebody and information is wanted.

G. L. SHELDON.

Ely, Nevada, September 30.

[The general samples and mill-tests do not mean much until we know who did the sampling. The assays "from zero to \$19" mean even less until we know how many inclined toward zero and how many approached \$19 per ton. The accuracy of any sampling will depend upon

the distribution of the gold; whether it be evenly distributed or whether it be confined to veinlets or patches in the mass of quartz. If the supposed ore rose 800 ft. above the surface it should be possible to sample it by driving one or two cross-cut tunnels, and then sample the sides of the tunnels in 5-ft. sections.—EDITOR.]

## A Criticism

The Editor:

Sir—I wish to express my appreciation of and say that I am greatly pleased with the new 'headpieces' with which you are introducing the various departments of the magazine. They are cleverly chosen and well drawn, with one exception, and without that you would never have heard that I liked them.

Being not only a miner but a motorist, I wish to enter a vigorous protest, in the name of 'Safety First' against allowing your artist to employ a chauffeur (in the Review of Mining) who will stop on over a 15% grade with a 'flat' less than a car-length ahead. A slight slippage of the brakes, considering the position he is standing in, might dislocate Mr. B. A. Stockholder to such an extent that all of the arguments of Mr. A. Geologist would be of no avail. If that point of view is absolutely necessary, make the 'prospect' walk.

LESTER S. GRANT.

Stent, California, October 19.

[The point is well taken.—EDITOR.]

## Flotation Physics

The Editor:

Sir—I have noted with interest in your issue of September 8, a discussion by Mr. Blamey Stevens of 'Flotation Physics.' In the course of the experimental work I have done in flotation, a line of reasoning very similar to that presented by Mr. Stevens has often suggested itself to me, and I should like to say a word or two in that connection.

In the first place, if Mr. Stevens' hypothesis be correct, we should expect that the best conductors would float best. It has been my experience that native copper or silver are almost impossible to float unless filmed with sulphide or something of the sort, although copper and silver metals are both excellent conductors.

Secondly, Mr. Stevens argues that the latent negative charges on the surfaces of conductors will attract and repel oil-films and ions outside the surface. As he previously states in his article, a distributed charge of electricity will act upon bodies outside as if it were concentrated at its geometrical centre. It would appear to me that the latent surface charge would act in this manner, and would be equal to and opposite in sign to the residual charge in the interior of the conductor. Acting from the same centre, their combined effect outside would be zero. This I have always understood as the reason for saying that the charge is latent.

For considerations such as the above, I have always

felt that a theory of this sort did not offer as logical a picture of the mechanism of flotation as might be desired. In fact, I might go further and say that my present opinion is that it is not advisable to explain flotation in terms of electro-statics. My reason is that some of our leading physical chemists say that ordinary laws of electro-statics do not apply at molecular distances.\* Consequently, a scientifically acceptable electro-static theory must be so complicated as to be practically useless to the average engineer or millman. We are also told, however, that chemical reactions, adhesion, adsorption, surface-tension, and many other phenomena, are fundamentally due to electro-static or electro-magnetic attractions and repulsions between the various atoms and molecules involved, possibly somewhat as Mr. Stevens outlined in the first part of his discussion. This being the case, we should be able to express the attractions and repulsions occurring in flotation in terms of chemical affinities. In doing so, we not only make our theories similar to those used by many scientists in explaining condensation and evaporation, sublimation, crystal structure, and many other apparently physical phenomena, but we are using terms and laws far better understood among metallurgists than many now found in flotation discussions. This idea was first suggested to me last winter by Mr. Schwartz, in much the same language he uses in his letter published in your issue of July 7, 1917. I have collected data since then which makes it appear that a satisfactory theory of flotation can be so presented in terms of chemical affinities. Lack of time and space prevent a full discussion of this at the present time, but I hope to find an opportunity soon to present my ideas in detail.

JAMES A. BLOCK.

Hayden, Arizona, October 25.

[This interesting letter should provoke discussion. We invite flotation experts to take part.—EDITOR.]

CALCAREOUS MARL used for soil-sweetening was reported to the U. S. Geological Survey, in 1916, from Arkansas, California, New York, Pennsylvania, South Carolina, and Virginia, according to returns compiled by G. F. Loughlin. The output was 35,588 short tons, valued at \$107,768, or \$3.03 per ton. Individual reports gave prices ranging from \$1 to \$3 per ton in the Southern States and from \$4 to \$6 per ton in the Northern States and California.

PLATINUM production in Colombia is expected to increase materially during the coming year. Prospecting has shown that the metal occurs in the stream gravels and in the high gravels for long distances on the Atrato and San Juan rivers in the Department of the Chocó. The most important operations are those of the South American Gold & Platinum Co. along the Condoto river, and the numerous native washings in the vicinity of Istmina.

# Origin of Nitrates in Cliffs\* and Ledges

By HOYT S. GALE

\*The prominence given to the subject of nitrates and the necessity of establishing a domestic nitrate supply both for munitions and for agricultural use, has naturally directed attention to the possibility of finding workable deposits of these salts within our own country. Nitrates exist in small amounts in many places, and nothing is more natural than that the prospector should attempt to follow these indications to their source, in the hope of discovering some large body of material containing a sufficient percentage to justify its exploitation. It appears that many well-informed people are being misled by small amounts of these salts, found in many places, so that it would be well, while this campaign of exploration is going on, to give thought to the peculiarities of the occurrences of nitrate in nature, and the way in which it is known to be formed. Consideration of this point may eliminate much unnecessary work and expenditure in prospecting. Turning to an encyclopedia we find: "Saltpeter (or nitrates) occur but seldom in strata, being for the most part a product continually formed by the action of nitrifying bacteria upon decomposing protein in the presence of oxygen." Protein is the name given in organic chemistry to a class of compounds found in animal and vegetable tissues made up of the elements carbon, hydrogen, and oxygen, together with nitrogen in chemical combination, the class being distinguished from other organic compounds by the presence of the combined nitrogen. Nitrogen in this form is generally called organic or albumenoid nitrogen. Protein is regarded as one of the most essential constituents of food for man and animals. It is represented by the albumen of the egg, the gluten of the wheat, and certain parts of meat and blood, as well as various grains and seeds. Although protein is food for animals, and is generated in plants, it is not directly available as food for plants that require nitrogen in the form of a nitrate, that is, a salt of nitric acid. Nitrates are essential to the growth of plants, and are present in all fertile soils, in which the nitrates are formed mainly by the action of nitrifying bacteria.

These nitrifying bacteria are present almost everywhere that conditions are favorable. They are found in practically all soils, and nearly everywhere on the surface of the earth. They have been found on the surfaces of rock masses high in the mountains. They become active as do other more familiar ferments, as for instance the yeast in dough, under proper conditions of warmth and moisture and with access to the oxygen of the air, and they become less active or quite inactive in the absence

of any of these favoring conditions. The farmer treats his soil to exactly the conditions leading to the best results, and one of the principal results is that the nitrifying bacteria become active and supply nitrate for the growing plants. There must be organic matter or humus present to support this action, as well as other conditions.

Large quantities of commercial nitrate salts are produced today by taking advantage of bacterial activity. During 1916 more than 2500 tons of saltpeter came from India to the United States, to be used mostly in munition manufacture. Nitrate is produced regularly in India, and in some other countries, by the cultivation under exceptionally favorable conditions, of organic wastes including manure, but chiefly the filth that accumulates about the dwellings of a none too sanitary population. This refuse is collected in small yards, is turned over from time to time so that it shall have proper aeration to promote bacterial activity, is protected from the leaching of rains during the wet season, is rendered slightly alkaline as one of the conditions favoring the nitrifying action, and is then periodically taken up and leached to extract the nitrate salts that have accumulated in it. The same earth or soil is worked over and over, but organic refuse is continually added, and care is taken to keep the compost slightly alkaline.

The same thing that is being done artificially in India is going on in many natural accumulations of compost, either manure or the general refuse of animal life where animals are herded together. Cave-earths were worked as a source of saltpeter during the Civil War and at other times in the history of the United States. There is no doubt that the nitrates in the caves originated in an exactly similar way. Caves or cavernous ledges are the natural refuge of all sorts of animal life, including insects, birds, reptiles, and many of the larger animals. In these recesses they leave, not only excrementa, but bits of their food, hair, bones, flesh, and even grains, mixed in a soil that is often light and porous, and may be filled with twigs and dried leaves. This is probably stirred by the coming and going of the cave denizens. Parts of these recesses are often damp with ground-moisture, or with wind-blown storm-water or mist, and when damp and at the same time warm they are in an ideal condition to promote the activity of the nitrate-forming bacteria. Thus it is easy to account for the accumulation of saltpeter or nitrate salts in caves, and in the cavernous recesses of rock-ledges.

Nitrate salts are so extremely soluble in water that they readily dissolve in ground or surface-moisture. They are continually forming in soils and as continually being washed away, so that there seldom exists any consider-

\*By permission of the Director of the U. S. Geological Survey.

able accumulation of nitrates in soil. In caves, too, the nitrates are largely washed away in the same manner. In places more protected from such action the accumulations found have been formed. Even these are doubtless variable, the product found at any one time being the difference between what has been formed or brought in and what has been carried off. The ready solubility of the nitrate salts accounts for one other factor in the accumulation of such deposits, namely the migration of the salts from the soil or place of formation and its recrystallization on the walls of the rock, in crevices, and even in the cavities of a porous rock. Almost everyone is familiar with the tendency of a soluble salt to take up moisture in a moist climate, and to creep up the sides

almost invariably be traced. With this explanation it is seen that a source for the nitrate is found which is active only at the surface, and does not account for the formation of deposits in depth away from access to the air. This accords with the facts observed in all cases where attempts to exploit the deposits have given opportunity to compare the surface with the underground evidence. There are many variations which will lead the prospector to think that his case is different from the type described. For instance, how is one to account for the fact that a test for nitrate may often be obtained on a barren hill-slope, in a soil just below the surface layer, especially in certain peculiar clay soils? The explanation is, however, the same as in the more definite cases cited above. Even these apparently barren soils contain much organic

PROSPECTING FOR NITRE, VALE, OREGON

of the container, often spreading considerable distances. Nitrate formed within a cavern will thus creep wherever the air or the ground-moisture can take it, and will crystallize where the evaporation of the dissolving moisture may leave it. Such evaporation can not go on in the depths of the earth away from access to the air, so that the accumulation of such crystalline crusts can not be looked for at a distance from the surface nor where the air can circulate.

The foregoing is an adequate explanation for most of the occurrences of nitrate salts that have been reported from many parts of the United States. Very often the nitrate is found in direct association with cave-earth rich in decomposing organic material, and this earth will frequently give high results on testing for nitrate. Visible organic matter is not always plainly associated with the deposits of nitrate salts, but the connection may

matter, especially at the surface. Bits of animal refuse and vegetation are sufficient to show fixed nitrogen almost anywhere that a sample may be taken. In a semi-arid climate, the soluble salts formed in the soil are not so completely washed out as in moister climates, and not infrequently they collect in the soil in considerable quantity. If the soil be a 'gumbo' clay it is quite easy to imagine that a surface may seal over very effectively almost as soon as it becomes wet, and although the soluble salts in the surface may be washed away, a part will be carried down. As the surface dries, it cracks, and letting in the air, the drying of the underlying layer is promoted as a sort of secondary process. Thus, a lower layer rich in the soluble salts ordinarily characteristic of such soils is formed. This layer has, at a number of places, been found to contain nitrate in small amounts associated with sodium sulphate, chloride,

and possibly carbonate. The nitrate found in such places may be explained as the accumulation of ordinary soil-nitrate in the sub-soil, where it happens to be under such conditions that it is not more completely washed away.

The accompanying illustrations are taken from prospects on nitrate deposits of the type mentioned and will serve to elucidate the features described.

The question is often asked, how were the great deposits of nitrate in northern Chile formed, and is it not possible that something of the same sort might be found in this country? The origin of the Chilean nitrate deposits has been widely discussed and it can not be said that a positive answer has yet been given. However, the deposits in Chile are not unlike the hillside occurrences of nitrate-bearing soils referred to above, and it is not unlikely that they may have originated in the same way. The caliche, or nitrate-bearing layer in the Chilean deposits, lies just below one or two definite layers of what is essentially a surface-leached soil-zone. The soil in this case happens to be largely a mixture of broken rock, as it is the wash that lies between the bedrock of the hills and the almost flat fill in the floor of the inter-montane valleys. Rains in this region are so exceedingly rare that the soluble salts are not leached as they would be in almost any other country. Fogs are prevalent, which serve to dissolve the more soluble salts at the surface, and to carry them down. Ground-moisture is found at the shallow depth which is doubtless being constantly drawn toward the surface by capillarity and evaporated by the heat and dryness of the atmosphere during the day. Between these two influences the soluble salts become concentrated in a zone which is usually not far below the surface. The deposits are also localized regionally, as well as horizontally, and this may perhaps be accounted for in the same way, chiefly as a result of the movement of ground-moisture. In spite of the many fanciful explanations that have been given to account for the origin of the Chilean nitrate, it seems not unlikely that scientists will in the end come to an agreement that these salts were produced in the same way that they are being formed all over the world, and that the extraordinary accumulations in Chile are principally the result of the unusual climate at the place where they are found. As such a climate does not exist anywhere in the United States it seems unlikely that considerable deposits of this type will be found here. It is possible that some of the lower-grade accumulations of soil-nitrates might be turned to account if they could be found in sufficient quantity to make their exploitation worth while.

JAPAN exported goods in 1916 of a value of 1,127,468,000 yen, being an increase of 69.8% over the previous year. Of this amount 30% came to the United States. The imports had a value of 340,228,000 yen, or 8.6% more than in 1915, and 27% of this trade-movement represented shipments from this country. The present output of pig-iron in Japan is 1,000,000 tons per year.

## Lost Mines

Every mining camp has its story of romantic discovery. Those of us who have shared the bivouac of the prospector or the warmth of the stove in a frontier hotel have heard of men that won wealth at a stroke. The poor prospector that went out as Bill or Dick is promoted to Mister or Colonel. As one old fellow expressed it: "A man can hustle, and starve may be, while trying to find a mine, but let him make a strike and they'll want to give him an oyster supper when he ain't hungry." There is scarcely a mining community in the West but has its mythical "lost mine." There was the Blue Bucket in Oregon, the Lost Cabin in Idaho, the Nigger Ben in Wyoming; there were others even more famous, such as the Breyfogle and Gunsight, both lost mines in the Death Valley region; but the most famous of all was the Pegleg, which was said to have been found by a prospector called Smith. He had lost a leg and stumped around actively enough by aid of a wooden substitute. His "stamping ground," as they say, was among the sand dunes and rock ridges of the Colorado desert, in Imperial county, California. According to the story, Smith was journeying from Yuma to Los Angeles when he was overtaken by a wind that drifted the sand across the trail. When the storm had passed he climbed to the top of one of a group of three small knolls in order to ascertain his way. When he reached the top of this knoll he was astonished to find the surface covered with pieces of dark-blue quartz so rich in gold as to be nearly solid metal. So astounded was he by his discovery that he forgot to take his bearings and hastened down the hill to make his way as quickly as he could toward Warner's pass. As soon as he could get a burro and some supplies he returned to his treasure-trove, but it was nowhere to be found. For days he searched the desert unsuccessfully. The days became weeks, the weeks lengthened into months, the years slipped by, and yet he failed to find that golden-crested hillock. He made many journeys, varying his direction, changing his area of search. Finally, he lived in a dug-out and mated himself to an Indian squaw at the foot of the hill now called Smith mountain. He never found his mine and died with his quest unfulfilled. In his last days he became garrulous and told the secret to other prospectors, who, in turn, started on a still hunt for the golden treasure. They too failed. The newspapers of the West have retailed the story in various guise. Scores of men have searched for the Pegleg mine and many have died in the effort; for example, four men in one party that went out from San Diego in 1895. Perhaps you would like to know where it is, as described by Smith's squaw long after Pegleg had found a resting-place in the one prospect-hole to which every man comes at last: 30 miles southwest of Smith mountain not far from the Butterfield trail, which is the old overland route between Yuma and Los Angeles, at the summit of one out of three little knolls. But two of those knolls may have been sand-dunes that the wind shifts as it lists.

THE INSPIRATION MILL, WITH THE INTERNATIONAL SMELTER IN THE BACKGROUND

## Miami, Arizona: The Milling of the Ore—V

By T. A. RICKARD

Flotation constitutes an important part of the operations in the Miami mill, but in the Inspiration mill it is the whole thing. The Inspiration is the largest all-flotation plant in existence. It treats 19,000 to 20,000 tons per day; this is equivalent to about  $13\frac{1}{2}$  tons of ore yielding  $\frac{1}{2}$  ton of concentrate per minute.

Entering the building, I was impressed by the bigness of it and then by the relative simplicity of the mechanical arrangement. Next I noticed the smell due to the aromatic constituents of the coal-tar used in the flotation department, and then the heat. It was a warm day outside, but upon entering the mill the temperature seemed appreciably higher. The idea came to me that this was due to the heat generated by the grinding of the ore, but a thermometer placed in the classifier-overflow, that is, the finished product of a ball-mill in combination with a Dorr classifier, showed a temperature of  $70^{\circ}\text{F.}$  as compared with  $66^{\circ}$ , which was the temperature of the water mixed with the ore in the ratio of 3:1. Making allowance for the relative specific heats of the ore and the water, it is evident that the rise in temperature caused by the grinding is small, namely, only about 3 degrees. A further heating of the pulp is due to the introduction

of warm compressed air into the flotation machines, but this is balanced largely by the cooling effect of evaporation while the air is passing through the machines, so that this item also is negligible. Thus I had to conclude that the heat noticeable in the mill was due to the moisture contributed by the air passing through the flotation-cells and by the evaporation of the pulp in the launders and other parts of the mill. In short, I had stepped from an Arizonan atmosphere into one resembling that of Florida.

Each of the 20 sections into which the mill is divided treats nearly 1000 tons of ore per day, but it occupies a width of less than 17 ft., and a length of 273 ft. On the day of my visit the mill produced 708 tons of concentrate containing 29.52% copper and discharged a tailing assaying only 0.13% sulphide copper. The average sulphide-copper content of the tailing for the whole month was still lower, namely, 0.104%.

A complete flow-sheet of the mill is given herewith (Fig. 1) and on a smaller diagram the only change, made recently, is shown (Fig. 2). This is the addition of a small flotation-plant to re-treat the middling from the tables.

Each section includes two Marcy mills (8 by 6 ft.),

their axes parallel with the flow of the pulp. This pair of grinding-machines is separated by two duplex Dorr classifiers (6 by 27 ft.), the underflow from each classifier being returned to the nearest ball-mill for re-grinding, forming a closed circuit. The overflow from the classifiers runs over a screen, so as to remove chips of wood in the ore, and then direct to the flotation-plant.

This consists of several kinds of machines, one section being provided with a Hebbard machine, four with Callow cells, and the other 15 sections with a somewhat different type of porous-bottom machines designed on the spot. These last, called the Inspiration machines,<sup>1</sup> are the biggest of their kind, for each one of them is able to treat the pulp of an entire section, namely, 1000 tons of dry ore and 3000 tons of water. First the pulp, with its emulsified oil, goes to the roughing-machine, which in its later form is made of steel, 51 ft. long and 11 ft. wide over all, being subdivided into two double series of cells each 4 ft. 3 in. by 3 ft. At the end of each series of eight compartments the pulp can overflow, so that the level of the pulp in the preceding compartments is maintained at a constant level. The air that makes the froth is admitted above a solid cast-iron bottom and below a false bottom that serves as a porous medium. This consists of canvas protected on its upper side by an iron grate. From this first flotation machine the concentrate goes to a 'cleaner' of similar design but smaller. It has six double compartments 3 ft. square. The consumption of air is 4000 cu. ft. per minute per section, at a pressure of 4.5 lb. per square inch. The power consumed in supplying this air is 87.5 kw. per section or 2.1 kw-hr. per ton treated, to which about 10 kw., or 0.24 kw-hr. per ton, must be added for the pumping of cleaner-tailing.

The tailing from the cleaner is pumped back to the rougher. Meanwhile the tailing from the rougher goes to a drag-classifier, which separates it into sand and slime, the first being re-classified by Deister hydraulic machines, the sandy product from which is concentrated on 11 Deister double-deck tables. The slime from the various classifiers joins the tailing from the Deister tables as a final reject, which is treated by Dorr thickeners in order to reclaim as much of the water as possible.

Water is added to the coarsely crushed ore, or mill-feed, when it enters the ball-mills. The Dorr classifiers produce overflow-pulp of a 3:1 consistence. This is regulated by a float that responds to the density of the pulp. The float is attached to a thin wire connecting with a lever that swings between two contact-wires connected with an electric mechanism, which, in turn, operates a butterfly valve, thus admitting or stopping the flow of water in accordance with the rise or fall of the float. The various concentrates, from the Deister tables and from

the flotation machines, are sent to Dorr thickening-tanks (ranging from 60 to 80 ft. diam.), which provide 40 sq. ft. of settling-area per ton of concentrate. On top of these tanks is the famous notice, "Keep your dog away." It appears that vagrant dogs jump on the cake of slimy concentrate formed over the surface of the thickener, thinking it solid, with a result disastrous to the dog and annoying to the millman.

The spigot-discharge (1.65 solid to 1 water) from the thickening-tanks goes to Oliver filters, of 12-ft. diameter and 12-ft. face. Six of these are in position, and are required to treat the entire output of the mill, namely, 700 tons of concentrate per day; it is intended to add two more. They reduce the moisture to 17%, but the percentage varies with the proportion of insoluble material in the concentrate.

At the time of my visit the flotation tailing from one section was going direct to the Deister tables, without classification; but it appears that classification is slightly the more favored. In the sections using the Callow cells, the overflow from the drag-classifiers is subjected again to flotation. The middling from the tables was re-floated experimentally with such success that the mill-practice is about to be modified accordingly. Dr. Rudolf Gahl, who has charge of the technical operations, is unwilling to believe that the last word has been said, for he knows that flotation as an art is still in its beginning. One of the subjects being studied, as at the Miami, is the recovery of the oxidized mineral. Whereas the recovery of the copper sulphide is 90%, that of the oxidized mineral is less than 25%. Leaching experiments are in progress, the oxidized copper being converted into sulphate, which is precipitated by crushed limestone. The results are said to be encouraging.

The total cost of milling, including crushing and grinding, is less than 40 cents per ton under normal conditions. For the first half of the year it averaged 46 cents on account of high wages (sliding scale based on the price of copper) and high cost of supplies. The cost of operating the flotation department is just under 6 cents per ton, not including royalty. An average of 1½ lb. of oil is used per ton of ore. This means about 12½ tons of oil per day in the mill. A more significant figure is the quantity consumed in proportion to the flotation-concentrate produced: this is 49 lb. per ton. The oil is fed into the scoop-boxes of the ball-mills. Formerly a mixture of 95% crude coal-tar and 5% pine-oil was used, but it has been found that since the proportion of re-claimed water to fresh water used for milling purposes has increased, it is possible to reduce the quantity of pine-oil to the vanishing point. Nothing but coal-tar was used for considerable periods. Dr. Gahl used to think<sup>2</sup> that a slight admixture of a wood-distillation product was needed to produce a multiplicity of small bubbles for the saving of the minutest mineral particles, but he now finds it is not necessary, if the consumption of fresh water is kept low. When work was first started at the

<sup>1</sup>Excellent descriptions of the mill and its operations will be found in the September 1916 bulletin of the A. I. M. E. 'History of the Flotation Process at Inspiration,' by Rudolf Gahl. 'Mine and Mill Plant of the Inspiration Consolidated Copper Co.,' by H. Kenyon Burch.

<sup>2</sup>Op. cit. supra.

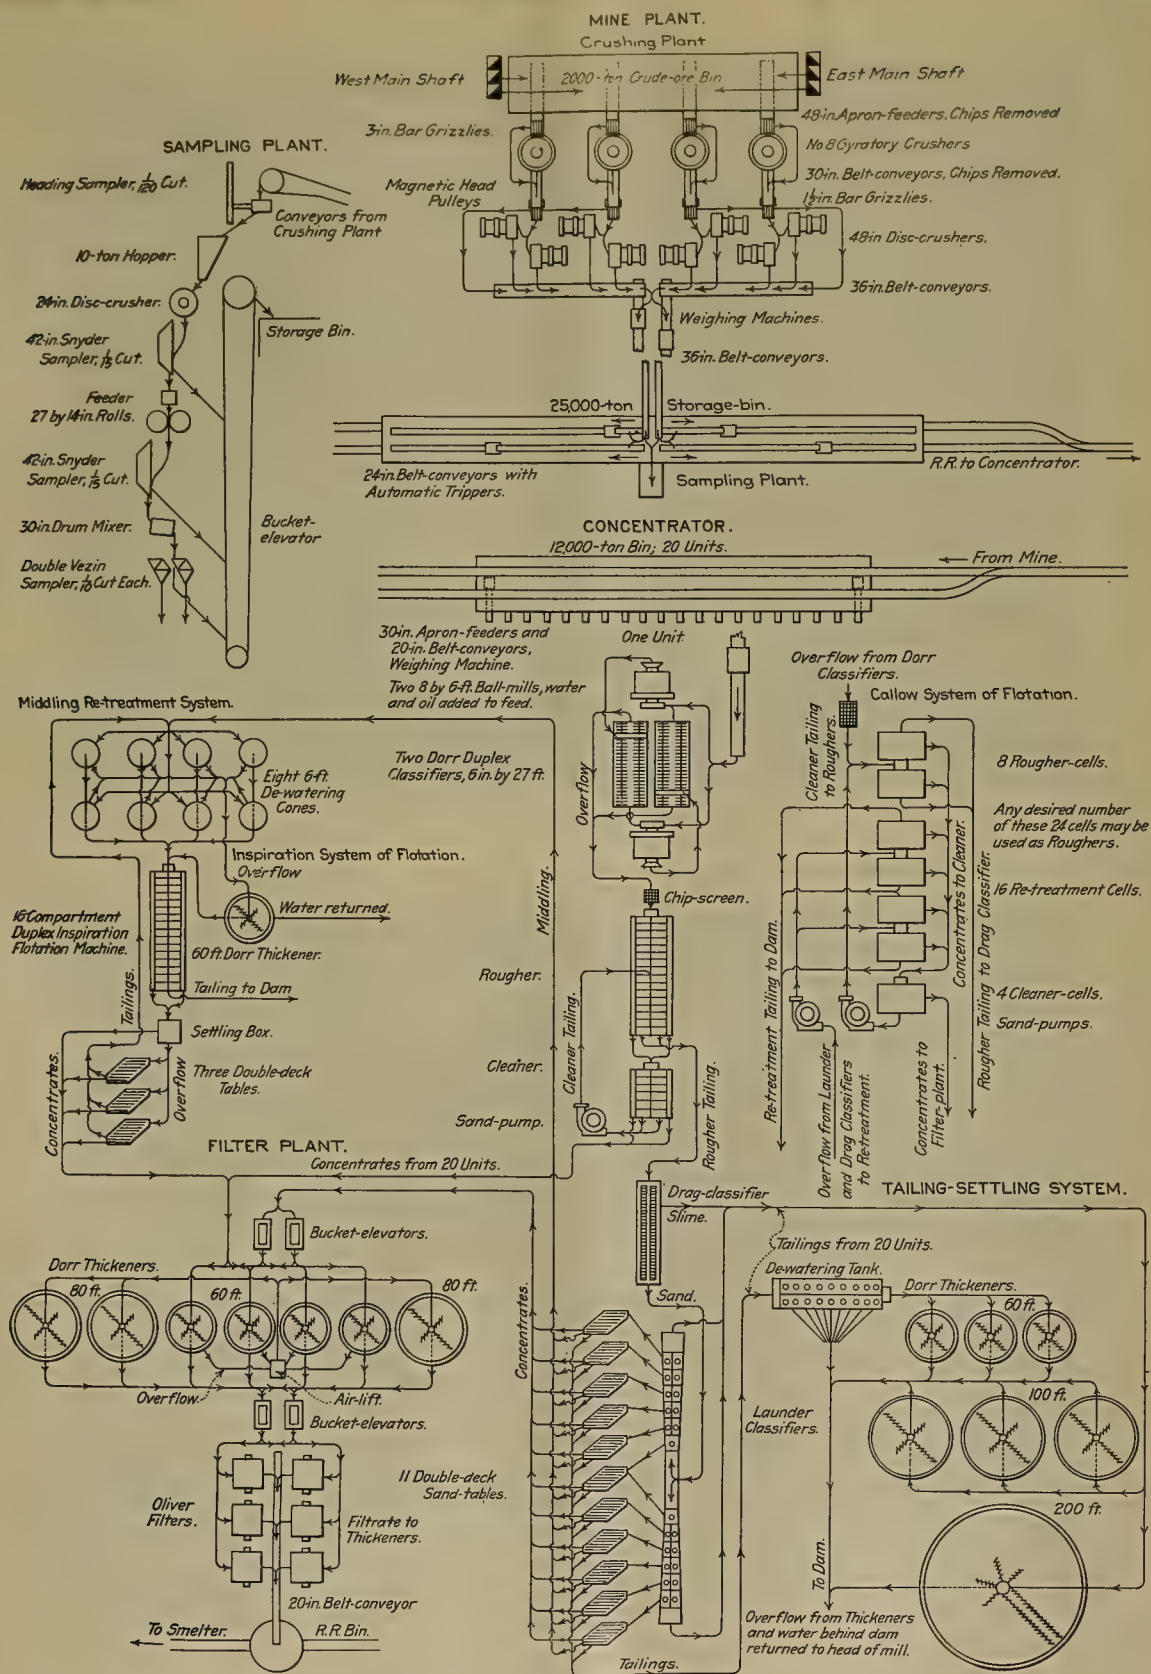

FIG. 1. FLOW-SHEET OF THE INSPIRATION MILL

Inspiration it was the practice to use one pound of flotation-oil consisting essentially of cresol at 30 cents per gallon (now 60c. per gal.); at the present time  $1\frac{1}{4}$  lb. coal-tar at less than 6c. per gal. does the work. These prices do not include freight. This marks a distinct advance in the economics of flotation, even if the physical explanation of the change is yet less assured than the value of the money saved.

The ore that comes to the mill is hauled 1.6 miles, from the mine, for  $1\frac{1}{2}$ c. per ton. The mill-bins hold 12,000 tons and are of the suspended type. They are made of sheets of steel in a catenary curve, which represents the most economical shape for a bin of this type. The mill is served by three cranes, one of 60 hp. and two of 40 hp. A broad-gauge incline runs along the side of the building, so that parts of machinery needing repair are carried on a flat car to the machine-shop, where they are lifted by another 40-hp. crane.

The history of the design of this big mill, and of the metallurgical processes conducted within it, is well worthy of American enterprise. In order to go back to the first suggestion of flotation, I must record the fact that on December 6, 1911, Edward H. Nutter, the representative of the Minerals Separation company in San Francisco, received a sample of chalcocite ore, sent to him by I. L. Greninger, from the Joe Bush dump. A test on that sample yielded a 9% concentrate and a 0.4% tailing on a 1.4% ore. Other samples were tried, with equally poor results. Nothing more was done until November 1912, when another series of tests was made, using the slide machine. On a 2% ore, a 15% concentrate was obtained, with an 85% recovery, and a 39% concentrate with a 55% recovery, according to Mr. Nutter. The various tailings ranged between 0.11 and 0.2% copper. These tests were made by F. A. Beauchamp, also in the Minerals Separation laboratory at San Francisco. A telegram stating that a 15% concentrate could be obtained on an 87% recovery was mutilated on its way to New York and was caused to state that a 50%, not 15%, concentrate could be made. This telegram caused considerable elation to the parties concerned, notably Dr. S. Gregory of Minerals Separation and W. D. Thornton of the Inspiration company. The immediate result was the erection of a small testing-plant by the Minerals Separation company at the mine in December 1912. In describing the big hole<sup>3</sup> made by the underground mining operations on the Joe Bush mine, I mentioned the remains of this 50-ton plant in which the first local experiments on Inspiration ore were made by representatives of the patent-owning company, notably I. L. Greninger and G. A. Chapman.<sup>4</sup>

The test-mill consisted of two sets of rolls, one Chilean mill, one Hardinge pebble-mill (6 ft. diam. by 12-in.

cylinder), a Richards hindered-settling classifier, two Deister tables, and one M. S. flotation machine of the so-called standard type. This mill ran for eight hours each day and treated about 10 tons in that time. It was in use from January to June 1913. Good results were obtained, but at first it was intended to float only the tailing from the gravity-concentrator. The testing of the various kinds of ore existing in the mine was one of the principal purposes of this test-mill. To this end 10-ton lots from various places were supplied and investi-

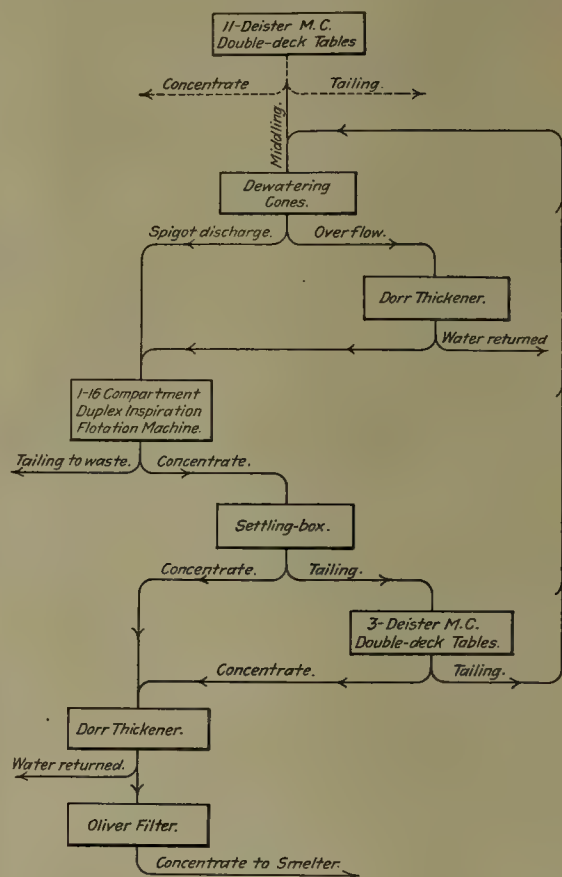

FIG. 2. FLOTATION PLANT FOR RE-TREATMENT OF TABLE-MIDDINGS

gated in order to ascertain their suitability for flotation. It was ascertained that chalcocite in schist was easily floated, whereas any kaolinized granite, such as was found along fault-fractures, produced a colloidal slime that diverted the oil from its proper function. To overcome this obstacle to a good recovery, it was suggested by Mr. Chapman that the oil be added to the pebble-mill on the theory that it might come in contact with the mineral particles at the instant when they exposed fresh fractures.<sup>5</sup>

In order to check various doubtful points on a bigger scale, it was decided to build a larger testing plant. This was designed by H. Kenyon Burch and started in Janu-

<sup>3</sup>See previous article. Page 418. M. & S. P., September 22, 1917.

<sup>4</sup>Lewis R. Wallace, subsequently superintendent of the International smelter at Miami and still later general manager for the Andes Copper Mining Co., represented the Inspiration company in these tests.

THE SAME. MARCY MILLS, FLOTATION MACHINES, AND DORR DRAG-CLASSIFIERS

ary 1914. It was given a capacity of 600 tons, because C. E. Mills, the general manager, figured that a plant of this size would at least pay its own way and be large enough to take care of the ore furnished by the development work in the mine. Running the ore from the development work through the test-mill would give an excellent chance for checking the mine-sampling and for determining in a final manner the suitability of the ore for flotation. At this time Dr. Gahl began to take part in the technical operations.

Grading for the existing mill, also designed by Mr. Burch, was begun in August 1913. The erection of steel was begun in March 1914 and the mill was completed in February 1916.<sup>a</sup> It likewise was intended mainly for gravity-concentration, and a contract for structural steel had been made when the general manager, Mr. Mills (to whose good sense and mature experience so much of the success of this great copper-mining enterprise is due), decided that an all-flotation plant was amply justified. Each section, with its two Marcy mills, was expected to grind 600 tons per day, but this anticipation has been much exceeded, as already recorded, for the capacity of some sections is now above 1000 tons per day. It was found also that the capacity of the flotation units could be increased commensurately. Thus the mill, despite a capacity 66% greater, occupies a floor-space of 50% less than was originally designed. It will be noted that much care was taken in experimenting before a large plant was built, but, once the experiments appeared conclusive, the erection of the big mill was undertaken with the least possible delay. This record of achievement does credit to all concerned.

The concentrator report for May 12, the day of my last visit, showed:

Tonnage (total time) .....	19,348.9
Average number of sections running.....	19.469
Average tonnage rate per section.....	993.8
Assay of feed .....	1.30
Screen-analysis of feed (on 48-mesh).....	3.8
Oxide copper in feed.....	0.28
Flotation concentrate .....	38.43
Table concentrate .....	14.30
General concentrate (from filters).....	29.70
Insoluble in general concentrate (from filters)	32.4
Moisture in general concentrate (from filters)	17.5
General tailing .....	0.35
Oxide copper in general tailing.....	0.26
Recovery of copper .....	73.96
Recovery of copper sulphide.....	91.47

BORAX should be free from arsenic and from sodium carbonate. Much of the refined borax of commerce contains, by weight, more than four parts of arsenic per million. Such borax should not be used as a food preservative. Likewise sodium carbonate is an injurious adulterant except when the borax is to be used as a water softener. In any case, borax adulterated with sodium carbonate should be so declared, and should sell at a correspondingly reduced price.

<sup>a</sup>This refers to 18 sections of the mill, two more were added later and brought into service during April 1917.

## British Standard Alloys

Interesting details of the composition and permissible variation in content of the alloys cast at the Royal Mint, London, are contributed by W. J. Hocking in a paper read at the recent annual general meeting of the Institute of Metals. The metals are generally procured in the form of fine ingots, and are alloyed in the proportions shown in the following statement:

Standard gold, 91 $\frac{3}{4}$ % gold, 8 $\frac{1}{4}$ % copper.

Imperial silver, 92 $\frac{1}{2}$ % silver, 7 $\frac{1}{2}$ % copper.

Coinage bronze, 95% copper, 4% tin, 1% zinc.

Cupro-nickel, 75% copper, 25% nickel.

In addition to the fine ingots and alloys, the average charge, to the extent of about one-third of the total, consists of scrap-metal from the various processes of manufacture, returned for melting. The bars cast are about 2 ft. long, but differ in width and thickness according to the denomination of coin desired. The width varies from 4 inches in the case of bars for bronze coins, to 1 $\frac{1}{4}$  in the case of those for three-pence pieces; and the thickness from  $\frac{3}{8}$  in. for cupro-nickel bars to  $\frac{5}{8}$  in. for bars for coinage bronze. In another department the bars are rolled to the thickness of the coin required. The average weight of the different classes of coinage-metals cast annually during the last five years was about 2000 tons, or a mean rate of a little over 7 tons (7000 kg.) for the working day. In melting gold and silver for coinage, great care must be taken to secure the correct proportions of metals in the alloys as finally turned out, in accordance with the legal requirements. The limits of variation from exact fineness are narrow, and are specified in the Coinage Act of 1891 as two parts per thousand for gold and four parts per thousand for silver. The variations permitted in practice are much less than these, and the necessity that the bars cast should be uniform in composition tends to restrict the size of the charges. The volume of the charge is mainly determined by the convenience of stirring it when molten and before pouring. Gold and silver are isolated in their respective pots until they are reported by the assayer to be either suitable or unsuitable for coinage. The usual charge of standard gold is 2800 oz., or 87 kg., and of silver 6000 oz., or 187 kilogrammes.

HOOKWORM infection is reported in the case of 444 miners out of 1440 examined in the Mother Lode district of California, according to a circular just issued by the U. S. Bureau of Mines. The investigation was made by Dr. James G. Cumming, director of the Bureau of Communicable diseases of California, in co-operation with Joseph H. White, sanitary engineer for the U. S. Bureau of Mines. Of those infected, 91 have taken treatment and have been freed from the infection.

TIN-PLATE will be produced on a larger scale next year than ever before. The demand is leading to the erection of many new tinning plants.

# Factors in the Production of Electrolytic Zinc

By R. G. HALL

\*An article on the subject of electrolytic zinc no longer needs to be preceded by an apology. The production of zinc by electrolysis is past the laboratory stage and has become an economic factor of importance in the United States.

The various methods of procedure to be followed for the greatest economy of manufacture are fairly well known, consequently a detailed description of any method is no longer necessary or desirable. Assuming that, for the present at least, the electrolytic production of zinc will be confined to localities having developed water-power, a glance at the powers developed in the United States with their relation to known zinc ore-bodies of economic size, will not be without interest.

In the North-West are water-powers, developed and undeveloped, in Washington and Montana. These must bear a close relation to the rapidly growing zinc-production of the Coeur d'Alene and the Butte districts. The power of this territory is relatively low-priced, as compared with the cost of developing power from coal, and the near neighborhood of large bodies of somewhat complex zinc ores makes these water-powers of more than usual importance.

One of the large complex ore deposits of the West is in Shasta county, California, in the territory of the Northern California Power Co., and developments to utilize it in zinc reduction are under way. In Utah are developed water-powers in connection with such ore deposits as the Tintic and the Park City districts. Evidently the relation between the power and the value of the ore deposits is sufficiently close to justify further development, and such are already undertaken. Farther to the east is power development at points in Colorado in the neighborhood of the large and valuable complex ores of the Lake, Summit, and Eagle County districts, as well as those of the San Juan. In Arizona and New Mexico there is not, so far as I know, sufficient development of low-cost power to make attractive any particular effort to develop electrolytic zinc. Passing east from the Rocky Mountain region there is no further development of power on a large scale short of the Mississippi Valley. Here is the plant at Keokuk, Iowa, producing power, which, while perhaps not as low-priced as some of the North-Western powers or the older Niagara Falls power, when considered in connection with its economic position it may be regarded as a point of considerable advantage. Farther east is the power development at Niagara Falls, but from all accounts this is already taken up to the fullest extent and no power is available,

at least none in large quantities for electro-metallurgical work.

The electrolytic refining of copper requires power not alone for the electrolytic tanks, but it also requires large quantities of coal for heating the solutions with steam or otherwise, as well as coal of special quality for cathode furnaces. In the electrolysis of zinc solutions we do not have this requirement because, in general, the solutions do not require heating, but on the contrary require occasional cooling, and the temperature for melting the zinc is so low as not to necessitate a large amount of coal for the cathode furnaces.

The consumption of acids and chemicals in electrolytic-zinc production is relatively small. No matter what kind of ore is used as a supply of zinc, unless it should be an oxidized ore with considerable quantities of soluble carbonates other than zinc, the amount of sulphuric acid lost in a cycle is a small factor, and in a modern electrolytic plant the use of other chemicals than those for laboratory purposes may be considered as nil.

The relation of freight charges to grade of ore is an important one and requires to be considered more in connection with the general ore-supply than by itself. It is to be noted, however, that the basing point for lead and zinc, the principal metals with which we are concerned in this inquiry, is the Mississippi Valley, consequently the value of the refined product must be considered only in connection with some delivery point having a freight rate basis which can be compared to the rate from East St. Louis.

At the present time, of course, with much of our metals going for export, this factor is considerably complicated, but for the purpose of this paper we shall consider the cost of the metals f.o.b. Mississippi Valley points, or equivalent to East St. Louis basis.

The requirement for the electrolysis of zinc is zinc sulphate and zinc sulphate only. Most other elements found in the solution are harmful to the electrolysis of zinc sulphate. I have never found any that I could confidently say were beneficial. This requirement seems relatively simple, but when it is understood that this process is to be applied to the complex of ore minerals coming from available zinc mines, it will be understood that the production of pure zinc sulphate of standard strength is not the easiest problem in the world, yet it is only this problem that has stood in the way of the manufacture of zinc electrolytically for so long a time. The factors necessary to the production of a solid coherent plate of electrolytic zinc were well known, but it

\*Abstract: Bull. A. I. M. E., St. Louis meeting.

is only recently that we have been able to produce this pure zinc sulphate on a commercial basis and have been able to obtain the electric current at such a cost as to make the production of electrolytic zinc a possibility.

Inasmuch as sulphide of zinc as it occurs in nature is not soluble in dilute sulphuric acid for the direct production of zinc sulphate, it is necessary to roast sulphide ores in order to eliminate the sulphur and convert the zinc to an oxide or sulphate. The roasting of zinc ore for sulphuric-acid leaching presents a different problem from the roasting of the same ore for retort-smelting. In the case of retort-smelting it is necessary to eliminate the sulphur to the greatest possible extent. Sulphur remaining behind either as sulphate or sulphide, beyond a certain amount, is harmful. For the solution of zinc in sulphuric acid, however, only the sulphur remaining behind as sulphide, and not always all of that, is harmful or causes a loss of metal. Zinc that has been roasted to sulphate is, of course, not harmful and is even desirable, as the sulphuric acid combined therewith helps to make up for the mechanical and other losses in the subsequent process. Another difference in the two methods of roasting arises from the fact that in the roasting of ferruginous zinc ore for retort-smelting little attention is paid to that complex compound of zinc and iron which is generally formed in a roaster from such ores and is usually referred to as a zinc ferrate. In roasting Colorado ores for the production of spelter, I have found as much as one-third of the total zinc in the ore to be insoluble in a relatively strong solution of sulphuric or hydrochloric acid. A material such as this would be fatal if formed in quantity when the ore is to be subjected to leaching with dilute sulphuric acid containing only from 6 to 8%  $\text{H}_2\text{SO}_4$ . Fortunately, however, the conditions which produce the ferrate are not such as need necessarily prevail in the roasting of ores for leaching with sulphuric acid. The production of this material seems to be a function of temperature, fineness of ore, and of time. In roasting for the production of spelter the temperature is usually raised at the end of the roast for the purpose of decomposing the sulphates and the elimination of the last possible amount of sulphur, but in a roast for leaching with sulphuric acid, the presence of sulphates is an advantage rather than an objection, and consequently the high temperature is not necessary. When roasting a complex concentrate such as that from Colorado and the South-West, containing only about 35 to 40% zinc, most of the balance of the metal-content being iron, there is great danger that an undue proportion of the zinc will be insoluble. On roasting zinc ores for the complete elimination of sulphur, the loss of fine material carried out mechanically, and of zinc, lead, and silver volatilized, is appreciable. I had the doubtful pleasure of smelting several thousand tons of some of the earliest concentrate produced by flotation in Montana. The concentrate was roasted in the standard type of Hegeler kiln, and by the time it had dropped seven times from hearth to hearth, and leaked out of the doors and other

parts of the kiln, by no means all the original concentrate found its way into the retort. Subsequent practice has improved this, but the roasting of a zinc-flotation concentrate in a multiple-hearth kiln is not conducive to sweetness of disposition in the metallurgist.

When leaching the calcine with sulphuric acid, other metals than zinc may go into solution. Contrary to the general belief, the solution of iron is not a difficult one to deal with, as this element is rather easily removed. In case the concentrate contains copper, a considerable amount of that metal will be dissolved with the zinc. This removes the copper from the place where it ought to stay, namely, with the lead and silver, and takes it where it should not be, that is, with the zinc. Consequently it must be removed by a separate treatment. Other soluble metals and metalloids are treated in the familiar standard manner which needs no description. The handling of the residue from the sulphuric-acid leach is, however, of considerably more interest. The economically valuable metals in it are copper, lead, and silver, with some gold, and the method of smelting must be adapted to the metal of principal value, whether copper or lead. If the lead is high, as is frequently the case, the material will go to a lead-smelting plant where the copper is of secondary consideration. In many cases, notably in the South-West, the copper is the metal of principal value, and under these conditions it may pay to send the material to a copper smelter and sacrifice the lead. The losses in leaching are slight in the case of lead, silver, and gold, but may be considerable in the case of copper, depending upon the subsequent treatment of the zinc sulphate.

Considering the ore as produced from the mine and carried straight through to the production of the finished metals along the lines above indicated we have: (1) When the ore is concentrated for the purpose of roasting and leaching with sulphuric acid, it would be desirable that a concentrate should be made as high in zinc and as low in iron as possible. The loss in leaching will be directly proportional to the volume of tailing remaining and also somewhat proportional to the amount of iron in the calcine. (2) For an ore high in zinc and low in iron, there will not be much difficulty in roasting to a point that will make possible an economic extraction of the zinc. (3) A calcine containing 68 to 70% of zinc oxide, equivalent to about 55% metallic zinc, would leave a residue of about 35% when this residue contains 10% zinc; whereas, a calcine containing 40% zinc would leave a residue of nearly 60% when the residue contains 10% zinc. In the first case, there would be a loss of only about 6% of the original zinc, while in the second case there is a loss of approximately 15% of the original zinc, and with such a low-grade concentrate the loss is likely to be even higher. It is evident, therefore, that, as the grade of concentrate so roasted and leached is lowered, the losses in zinc may rise rapidly, not only relatively but absolutely, and this loss will become greater as the percentage of iron increases in

the residue. (4) Again it will be seen that only in those cases where the source of current is relatively near, or where the concentrate can be made high-grade, will it be permitted to follow this method of handling. Comparison of the total freight paid on the contents of a 50% zinc concentrate from Montana, landing 85% of the product in New York, is of interest as showing the approximate distribution of the freights paid and the relative amount of freight in each case.

2000 lb. ore to Mississippi river.....	\$7.00
5% moisture .....	0.35
850 lb. metal to New York.....	1.44
	—
	\$8.79
850 lb. metal, Montana to New York.....	4.31

Difference in freight paid on 1 ton 50% ore.....\$4.48

From the difference of approximately \$4.48 per ton of ore shown above, in favor of electrolysis at or near the mine in Montana, must be deducted such local freights as may be paid in case the power is not obtainable at the mine itself. This may decrease the difference as much as \$1 per ton. All of these conditions have to a large extent been fulfilled in the Montana and Idaho field, in that there can be made a high-grade concentrate with a high efficiency of concentration, and that there is power close to the ore-supply, so that in no case does transportation become a serious matter. The balancing of these factors is of the greatest importance for success in the production of electrolytic zinc.

The ores of Colorado are of a complex character which do not admit of a high ratio of concentration or of a good recovery. The cost of milling is relatively high and the recovery of all the metals contained is low as compared with the modern practice in simple ores. I approached this problem, therefore, with the idea of eliminating to the greatest possible extent this preliminary concentration, as many of the ores in Colorado are already what one could consider, in other industries than zinc, relatively high-grade. Where the ores as mined contain too much waste, or are too low in valuable metals, these can readily be concentrated to a product containing all the metals in a form which, though valueless for the retort-process, are easily treated by the method proposed. That is, the ores may contain from 15 to 20% zinc with varying quantities of lead, silver, and gold. It was necessary, therefore, to find a method for handling these. The problem was to find which would produce a high-grade simple concentrate, enabling such concentrate to be transported to a central refining point without incurring high freight charges, and then to put this concentrate into such shape that it would be relatively easily separable into its constituent metals. Concentration smelting, with the volatilization of the zinc and the lead, was consequently decided upon. Most of the ore-supplies of central Colorado today are of sufficiently high grade to permit of direct smelting in the blast-furnace, whereby the principal part of the precious metal is collected in a copper matte and the

zinc and lead are driven off as a fume and collected in the bag-house. This is the process as carried out at Florence, Colorado, today. The physical character of the ores must be such as to permit charging into the blast-furnace, or in the case of concentrate, it must be put into this physical condition. Again, the ore-charges must be balanced in such way as to give a slag that will carry the minimum of zinc to waste. The Colorado ores are of such varied character as to permit of the fulfilling of both of these conditions. The ores are charged without preliminary roasting; and with low copper content on the charge a first matte is generally made carrying sufficient metal to bear shipment directly to the refinery. Part of the silver in the charge is carried into the matte and the balance goes over with the volatilized metals into the bag-house. The volatilization of the zinc and the cleanness of the slag still leave much to be desired and interesting work in this direction remains to be done. Concentrate produced in this way will contain only those metals and metalloids that are volatile under the conditions of the blast-furnace, consequently it is a relatively simple mixture of oxide of zinc and sulphate of lead, with some sulphate of zinc and a small amount of silver. In this connection there is necessary a word of acknowledgment of the pioneer work performed on these lines by F. L. Bartlett in his smelter at Cañon City, Colorado, for a number of years.<sup>1</sup> An intimate acquaintance with Bartlett's work which I had the opportunity of obtaining some years ago really forms the groundwork for the practice in Florence, Colorado, at the present time. In such concentrate as this the zinc is readily soluble in dilute sulphuric acid, and the lead and silver are quite insoluble; consequently the purification becomes simple. The physical character of the material is such as to make it easily handled for shipment and easily handled in the leaching-vats. The metal content is high, and shipment is in the direction of consumption of the metals. This point must be borne in mind in connection with refining at Keokuk.

The residue of lead and silver is relatively small when figured back to the tonnage of the original ore handled, and being a finely divided heavy material, it is washed with considerable ease reasonably free from zinc sulphate. The treatment of this for its lead presents no great difficulty, as the only metals of economic value are lead and silver.

From the above it appears that, considering the character of the concentrate possible with these ores, and the situation of the power available for the electrolytic process, only some such method could be employed. It is true that the loss of zinc in the blast-furnaces is high, extremely high when compared with metallurgical work on other metals, but the endeavor is as far as possible to make the milling and smelting operations one, so that one loss covers everything, and I am inclined to think that, under the conditions, to have a big hole in one pocket is perhaps no worse than to have little holes in

<sup>1</sup>Trans. A. I. M. E. (1893), 22, 661.

three, or four. The freight on the zinc concentrate from the smelting point to the refinery becomes relatively small when figured back to the original ore, and in any event the concentrate is moving toward the market. Should such concentrate be moved in any other direction, the freight charge would become a direct charge on the cost of production which would not be redeemed in any way.

The cost of electric current in the production of electrolytic zinc is fortunately directly proportional to the metal recovered, rather than to the tonnage of ore treated. For this reason it becomes profitable to use it on a 20% ore or concentrate from Colorado, where it would not be profitable to use it under present conditions on a 60% concentrate from the Joplin district. Furthermore, when the actual cost of current per ton of ore is figured on a 20% ore it becomes, relative to the other charges incurred, only a small factor. In such case it would probably not exceed 25% of the whole cost of producing the metal and shipping to point of consumption, when based on the present power cost in most of the Eastern territory. The actual power consumed in the production of metallic zinc will be for most cases about  $1\frac{1}{2}$  kw-hr. per pound of zinc in the electrolytic tanks. Additions to this, of course, must be figured in the auxiliary power for the plant, transformer losses, conductor and other losses, all of which will be familiar to an electrochemist, so that altogether, probably, when working on central-station current 75% of the current purchased will go into the electrolytic zinc on the basis above mentioned. Costs on this basis need not be calculated, as each district will be a law unto itself, and power-contracts will be based on load-factor as long as central-station power is used. Central-station power is usually received as high-tension alternating current, and for the electrolytic tanks has to be stepped down and rectified. For the auxiliary power it has to be stepped down and may or may not be rectified, as the purchaser pleases. Load-factors in electrolytic work are usually high, approaching 100%, consequently the cost of horsepower per year can be figured almost directly into a kilowatt-hour cost; that is 0.1c. per kilowatt-hour is approximately equal to \$6.50 per horsepower year at 100% load-factor.

WOLFRAMITE is reported from the State of Rio Grande do Sul, Brazil. The mineralized area has been explored to a depth of from 8 to 9 metres and is found in over 8000 hectares of land. The property is 10 miles from the city of Lavras, and on account of the lack of railway facilities the ore has to be hauled by cart from that point to Lavras, whence it is shipped to Porto Alegre. Shipments from this property up to the outbreak of the War had been made regularly to Germany, the Krupp works having contracted for the entire output. In the years immediately preceding the War the exports from this mine are said to have averaged more than 1000 tons of 60% ore per year. The property could produce from two to three tons daily.

## Trinitro-Toluene for Mines

By MILTON A. ALLEN

The War has brought many changes. Among these is the entry of trinitro-toluene into the list of explosives for mining. Prior to the War there were few by-product coking-plants, and those that existed did not all recover benzene and toluene. The output of these substances in this country and in Canada has increased enormously through the demand created in the manufacture of explosives. The value of trinitro-toluene over picric acid for munitions was quickly recognized by the allied countries. The demand brought about the rapid increase in the recovery of benzene and toluene, as well as the erection of by-product coking-plants expressly for the purpose of recovering them. Also experiments were made by the U. S. Bureau of Mines and by explosive manufacturers for their production from crude petroleum. It is now claimed that it is possible to manufacture trinitro-toluene in normal times cheaper than nitro-glycerine.

The properties of nitro-glycerine explosives are fairly well known to the miner, but in spite of its wide use in rock-work it possesses many disadvantages. Exudation is liable to take place under circumstances depending upon the kind of absorbent used, the character of the wrapper, and the temperature to which it is subjected. Nitro-glycerine will also exude if the dynamite is left in a watery hole for a considerable length of time. Trinitro-toluene being a solid at ordinary temperatures, and melting at about 81° C., would not be subject to exudation. Nitro-glycerine explosives are liable to freeze at a moderately low temperature, that is, about 13° C., whereas trinitro-toluene remains unchanged. Nitro-glycerine explosives, although less sensitive to detonation when frozen, are erratic and may explode on receiving a slight blow. Nitro-glycerine is also slightly volatile at ordinary temperatures and, having a powerful physiological effect, handling will often produce headache. Neither is this effect produced by trinitro-toluene. It is the most stable explosive known. When heated it does not ignite until a temperature of 300° C. is reached and even then it does not explode, though it decomposes slightly at 150° C. One disadvantage is that when it explodes, a large amount of carbon monoxide gas is given off. This, however, could be overcome by the presence of a nitrate as an oxidizer, as is done with dynamite.

From the foregoing it will be seen that trinitro-toluene possesses advantages which make it of peculiar interest to the miner as an explosive. Many plants that are now manufacturing trinitro-toluene for war-purposes face complete shut-down when the War is over unless they can enter the field as producers of explosives for mines. Apparently the difficulty is to put the trinitro-toluene into usable form for these purposes, and to educate the miner to use it. The advantages on the side of safety and convenience are unquestionable. The great increase in by-product coking will, furthermore, render it important to utilize these in this manner after the War.

# Concentration Practice in South-East Missouri

By A. P. WATT

\*The problem of concentrating the disseminated lead ore of south-east Missouri is extremely simple. The economic mineral is galena and the gangue dolomite. The ore assays from 4 to 6% lead, 80% of which is recovered in a 70% concentrate. The ore is crushed through 10-mm. and sized on 2-mm. screens; the oversize is jigged, while the undersize is tabled, and the slime treated by flotation. The district is the largest lead producer in the world, the output of metallic lead for the year 1915 being 183,906 tons. Over 20,000 tons of ore per day is being treated. The management of the different properties is progressive and always open to suggestion. The fact, however, must not be lost sight of, that the special problem in the district is peculiar, as the average ore contains but 80 to 120 lb. of a metal normally selling at about 4c. per lb. The low price of the metal limits the treatment-system to one of low cost. An elaborate treatment is neither logical nor advisable. An engineer first visiting the district may consider that the method of treatment could be improved and, in some cases, this may be the case. On the other hand, the method of treatment followed is largely one developed by evolution and, consequently, is probably not far from correct. However, the ultimate method of treating the ore is a problem that has not yet been solved. The methods of concentration used at the different properties are practically identical, differing not in principle, but in detail. This is because of the similarity of the ore in the different properties.

The usual method of treating the ore is as follows: It is given an initial crushing in gyratory breakers, later finished in rolls to pass the first screen, which is 9 or 10-mm. round-hole punched plate. Water is first added to the undersize of the first limiting screen, the pulp passing to the second limiting screen. This size varies to some extent, the usual size, however, being from 1½ to 2 mm. Punched plate with round holes is used entirely on the second limiting screen, woven wire not being used for screening. The oversize of the 2-mm. screen passes to Hancock jigs which yield concentrate, middling, and tailing. The concentrate is either a finished product or else it passes to a re-treating plant. The tailing, in general, is an end product. The middling is generally crushed in high-speed rolls, but much work is being done in an endeavor to replace them with re-grinding mills; Allis-Chalmers, Hardinge, Marathon, and Marcy mills being now tested for the purpose of re-grinding middling. It is desirable to crush the jig-middling through a 1½ or 2-mm. trommel. Formerly the

re-ground middling was joined with the original feed, but at present the usual practice is to keep them separate. The discharge from the middling rolls, or re-grinding mills, is sent to the middling elevator, which discharges to the middling-screen. This is generally a trommel covered with 1½ or 2-mm. punched plate, the oversize of which may be sent to a middling-jig or to the jig treating the original feed. There are two undersize products to treat on the tables, the original undersize and the middling undersize. They may be combined, but are generally treated separately; the latter course is the logical one. The original undersize is comparatively small in amount, but contains much galena and little water. The contrary is true of the middling undersize; here the tonnage is large but of low grade, and this product contains all of the circulating water in the middling system.

The method of treatment given each of the two products smaller than 2 mm. is practically identical. The product may be classified, each spigot going to tables, or it may be de-slimes in any of a large number of de-sliming machines. In this latter case, which is the more common, the de-slimes spigot is treated on Butchart tables. In any event, whether the table-feed is classified or simply de-slimes, the sand tables make a final tailing, a concentrate that may be final or re-treated, and a middling. This middling is circulated, re-tabled or re-ground, and generally joins the main stream of middling at the middling elevator. The table middling contains considerable pyrite which builds up in the system, and this 'iron', as it is locally called, is now being ground through 80 mesh in ball-mills and tabled, the tailing going to flotation.

The overflow of the de-slimes apparatus or the classifiers may pass directly to the flotation plant, or else be first sent to the slime-table department for treatment before going to flotation. If the latter course be taken, the overflow of the de-slimes cones is settled, the spigot is tabled, yielding a concentrate and a tailing. The concentrate is a finished product and the tailing is combined with the overflow of the settling tanks in the slime-table department and sent to flotation.

At the flotation plant the slime is settled in Dorr tanks, the overflow being sent back to the mill-water system. The spigot product, thickened to 20% solids, goes to the flotation machines, of which both agitation and pneumatic types are used. Creosote is the usual frothing-agent employed. The flotation concentrate is not re-treated, while the tailing generally receives further treatment. Re-treatment of the tailing generally consists in sending the primary tailing to pneumatic machines,

\*Abstract of a paper read at the St. Louis meeting of the A. I. M. E., October 1917.

which make a final tailing, and a concentrate that may be final or may be cleaned later. The general flotation-concentrate is settled in Dorr tanks, the spigot product is treated by Oliver filters, the cake from which contains 50% lead and 14% moisture. It is loaded into box-cars and shipped to the smelter, but separate from the jig and table-concentrate. The general mill-tailing is stacked by conveyor-belts, as the topography of the ground does not permit of disposal of the tailing by gravity alone. The tailing from the flotation plant is either pumped to the 'chat' pile to be used as flushing water, or else sent to a slime-settling pond. For operating and metallurgical reasons, the mill-concentrate is kept separate and distinct from the flotation-concentrate.

No crushing is done underground in the district, all being done at the mills, with the exception of a few cases where coarse-crushing is done at certain shafts, the crushed ore then being transported to the mill. The usual practice in the district is to centralize the crushing plant at the mill and, as would be expected, the use of the gyratory type of crushers is almost universal, although one of the older plants still retains the jaw type.

A typical installation would be as follows: The run-of-mine ore is fed from the crude-ore bin to the primary gyratory crushers. They are usually either No. 6 or No. 7½ of the standard makes. The ore is generally fed direct without preliminary screening of the fine. The feed may be regulated by arc-gates operated by air or by the usual type of air-operated gates. The use of steel-pan conveyors in the capacity of crusher feeders is becoming common practice, as with a slow-moving pan conveyor a very large gate-opening can be permitted, thus preventing 'choke-ups' due to large rocks. The pan conveyors prove satisfactory for this purpose, being operated either by an adjustable ratchet and pawl or by a variable-speed motor. The discharge of the crushers passes to trommels, the oversize in general passing to the fine-crushing gyratories. At one plant, however, the discharge from the first gyratory passes, after screening, to 48-in. Symons horizontal disc-crushers. At another plant, the discharge from the first gyratory crushers, after screening, passes to Symons vertical disc-crushers, which are capable of making a reduction from 3 in. to approximately ½ in. This arrangement, of course, simplifies the crushing and screening plant.

There is nothing of particular interest about roll-practice in the district. The usual type is the high-speed roll, although two mills are still operating the Cornish type. The high-speed rolls are of the standard makes, the largest rolls in the district being 54 in. diameter. Rolls that crush sizes larger than 10 mm. are operated dry, while rolls crushing material finer than the first limiting screen are operated wet. The usual practice for dry-crushing is as follows: The ore is crushed to approximately 1½ or 2 inches in the crushing plant, then conveyed to and stored in the mill-bins. From here, after screening over 10 mm., the oversize is fed to the rolls, the roll-product passing to the elevator raising the original roll-feed. In other words, the elevator, screen,

and rolls are in closed circuit, the rolls crushing from 1½ or 2 in. to 10 mm. Graded crushing is not used in the lead belt, although graded roll-crushing is practised at one plant in the Fredericktown district, all roll-practice at that property being wet, due to milling conditions. Graded roll-crushing gives much better operating conditions than were formerly obtained by the use of a closed circuit, principally because the roll-spacing could be better adjusted. Both manganese and rolled-steel roll shells are used.

All crushing and screening is done dry in sizes larger than 10 mm. There are many screening devices used but the trommel is the usual type, and for heavy work it is supported on rollers at the feed end, the discharge end being supplied with a gudgeon. For 10-mm. screening, the usual type of shaft and spider trommel is used. The old type of conical trommel, as well as the hexagonal trommel, is used at one plant, but both of these types, as well as the cylindrical trommels, are being replaced by the flat screens of the Ferraris type. These are to be found at two mills where they have replaced or are replacing the cylindrical trommels. The flat screen has many advantages over a trommel, since the screening efficiency is higher and the wear on the punched plate is much less than that occurring on a trommel, and, for the space occupied, the flat screen has a much larger capacity than a trommel. The flat screen will also handle a greater volume of water than a trommel of the same screening capacity. The impact screen, as manufactured by the Colorado Iron Works Co., is being tested at one mill in the district. Flat stationary screens follow the coarse crushers in one plant, and another is using a rotary grizzly for removing the undersize of 4 in. before feeding the original ore to the primary crusher. As the finest screening in the district is done on the second limiting screen, corresponding to a 2-mm. trommel, it will be seen that the screening problem is not serious. About 80% of the screening is done with the standard trommel, and the remainder mainly on the Ferraris type of flat screens.

**JIGGING THE ORE.** The ore when crushed through 10 mm. readily yields commercial tailing, as at this size it contains much dolomite that is free from lead. This clean dolomite, however, gradually progresses to the condition of middling where the galena is finely disseminated. When crushed through 10 mm., the first free lead of any great importance occurs on 4.699-mm. screen. The jig-tailing will contain from 0.7 to 0.8% lead.

The Hancock jig is one of the noteworthy appliances in the district, since jigging in the lead belt is now limited entirely to the use of the Hancock jig. This belongs to the type of jig having a movable screen. The screen tray rests in the tank which is made of 4-in. lumber. The tank is 25 ft. long, 4 ft. 2 in. wide, and 10 ft. high. It is divided by five headers into six compartments, the headers being placed at any desired position. The products from the first two compartments are concentrate, the third spigot may yield a concentrate or a product for circulation, depending on operating condi-

tions. The fourth and fifth hutchers yield middling for crushing, while the tailing is discharged over the end of the tray into the last compartment. A chain drag of the Esperanza type is usually built into the last compartment, which drags the tailing up over the end of the jigs. The tray, as built, is 20 ft. 6 in. long and 3 ft. 2 in. wide, outside dimensions, built of lumber. One company has replaced the wooden tray by one of steel. A steel tray has many advantages over wood, being lighter, and, due to the increase in effective screen-width, the capacity of the jig is increased about 15%. The feed to the Hancock is generally crushed through 10 mm. on  $1\frac{1}{2}$  or 2-mm. screens. Very efficient work is done on this range of sizes.

In the past this district has made use of classifiers for preparing table-feed, the usual grade treated being the undersize of a  $1\frac{1}{2}$ -mm. screen. Nearly every type of standard classifier has been used, as well as the usual flock of home-made ones. The introduction of the Butchart table has done much to simplify the question of classification, and in practically every plant the classifiers have been either entirely displaced or largely replaced by apparatus for de-sliming only, so that the classification problem is not serious. In the past, use has been made of classifiers for preparing Harz-jig feed, and two plants for a while endeavored to use classifiers for preparing the feed to the Hancock jigs. This arrangement was not noted for its satisfactory results, and was replaced by screens. The present practice may be discussed under three separate headings, namely, classification, de-sliming, and settling. For all practical purposes, we can say that classification, in the usually accepted sense of the term, is not used in the district, preparation of table-feed being done by de-sliming apparatus. Much use is made of de-sliming appliances for preparing the table-feed. The problem is not very serious as, due to the large margin in difference between the specific gravity of the gangue and the galena, extremely efficient work is not of great importance. The de-sliming apparatus should eliminate from the spigot-product the galena too fine to be saved on the tables, and the overflow should contain a minimum of sand and lead that can be efficiently treated on the tables. This size is usually set at 150 mesh. The 2-mm. undersize is the largest now being de-slimed. Work has been carried on with undersize from the 3-mm. trommel with satisfactory results, so far as classification is concerned. De-sliming is accomplished by means of Dorr classifiers, drag classifiers, Akin classifiers, and de-sliming cones. The Dorr and drag classifiers, in some cases, send the sand-product direct to tables. In other cases, the sand is treated first in classifiers, or de-sliming cones, before tabling. At one plant the undersize from the 2-mm. screen is sent to a de-sliming cone, the spigot of which discharges to a belt-drag, which in turn yields a sand-product for tabling. Other plants de-slime the screen undersize in de-sliming cones, the spigot-product going direct to tables. The Delano cone is used at several plants, and is giving excellent results.

The problem of table treatment is simple and, due to the great difference in specific gravity between the galena (7.4) and dolomite (2.85), close classification is not essential. In the past, the usual method employed was to classify the feed and treat it on Wilfley tables, the usual size treated being the undersize from a  $1\frac{1}{2}$ -mm. trommel, but at present the table-feed is de-slimed and generally treated on Butchart tables. The usual size of feed to the tables is the undersize from  $1\frac{1}{2}$  or 2-mm. screens. The table-concentrate will average about 77% lead, while the tailing will contain about 0.3%. Probably the largest size of original feed to be tabled is the undersize from a 3-mm. screen. This yielded good results by tabling, but the wear of the riffles and of the linoleum was so great as apparently to offset the advantages gained by tabling this size. A Butchart table was used for the test, and with 90 tons of feed per table, the tailing assayed between 0.4 and 0.5% lead. The object of endeavoring to table this coarse feed was to remove the fine sizes from the jigs and, furthermore, to remove from the jigs as much of the galena as possible, thus reducing the loss due to abrasion. The excessive wear of the table-tops necessitated replacing the 3-mm. screen with a 2-mm. plate. The number of tables to each Hancock jig varies to a great extent. At one plant there are supplied three tables for each jig, at another plant there are ten tables for each jig. This ratio varies according to screen sizes and methods of middling and grinding. The average ratio is one jig to seven tables.

Re-grinding of middling is receiving a great deal of attention in the district. Two types of middling are being re-crushed, the jig-middling and the table-middling. The problem of crushing the jig-middling will be first considered. In the past, the jig-middling has generally been crushed in rolls, but now one company is using Chilean mills for crushing the fifth hutch-product of the Hancocks, and one company has just discontinued the use of Huntington mills. Rolls are used in all plants for crushing middling, and are exclusively employed for this purpose in five plants. Fine-grinding mills are being introduced at all the plants in order to determine the best mill adapted to this purpose. The Huntington and Chilean mills are not desirable. The result obtained by crushing the middlings in rolls is not satisfactory, and every attempt is being made to replace the rolls and other crushing machines with one of the newer types of fine-grinding mills.

The first company to introduce a ball-mill into the district for the grinding of jig-middling was the Desloge Consolidated Lead Co., which began operating a 6-ft. by 22-in. Hardinge mill in March 1916. Since then many different types of mills have been introduced, and fortunately the choice of the different companies was not the same, so at present the following types of re-grinding mills are operating: Allis-Chalmers, Hardinge, Marathon, and Marcy mills. An Allis-Chalmers ball-granulator is operating in competition with a 6-ft. by 22-in. Hardinge at one plant, and at another plant an 8-ft. by 30-in. Hardinge is running in competition with

a 4 by 9-ft. Marathon. The Marcy mill as yet is not directly competing with any other mill, as is true of the 4 by 10-ft. Marathon.

The feed to the fine-grinding mills is generally from the fourth and fifth hutches of the Hancock jigs, but one plant is crushing the jig-middling and the oversize of the 10-mm. screen in the ball-mill. The usual practice, however, is to take as feed to the re-grinding mill, the jig-middling which passes 10 mm. and stays on 2 mm. The fifth hutch of the jig will contain from 1.5 to 2.5% lead, and the fourth hutch may assay from 8 to 20%, and it is generally desirable to crush the middling to pass a  $1\frac{1}{2}$  or 2-mm. trommel. The product should be similar, if possible, to that produced by roll-crushing, as the minimum of slime is desired. The feed to the re-grinding mills will assay from 3 to 8% lead, and after crushing through a  $1\frac{1}{2}$  or 2-mm. screen, an economic tailing and a clean concentrate can be produced and a middling for re-grinding in a separate circuit. By economic tailing is meant a product that cannot be further treated and yield a product. Test-work has shown that where a jig-middling is crushed through a 0.208-mm. aperture (65 mesh) practically 100% of the lead is free. It is thus evident that extremely fine grinding is not necessary nor desirable. The ideal product would be one that would just pass the limiting screen,  $1\frac{1}{2}$  mm. or other size, and have a minimum of material finer than 65 mesh. If a tailing can be made at  $1\frac{1}{2}$  mm., it is evident that it is not desirable to produce any larger tonnage below this critical size than is necessary. At the other extreme, no product is desired finer than the lower critical point at which all the lead is freed.

The term 'slime' has considerable latitude in the district and refers to the product passing a limiting screen of some definite size. Formerly 200 mesh was adopted as the common limit, but the introduction of large-tonnage tables has caused this definition to be slightly changed. These tables treat a 'de-slimes' feed, all material finer than 150 mesh preferably having been eliminated. It is thus desirable to overflow material finer than 150 mesh from the de-slimes apparatus, and this overflow is termed slime, since it is all minus 150 mesh. Some companies, however, still retain 200 mesh as the limiting screen, and references in this article will consider 200 mesh (0.047 mm.) as the limiting size. At present slime is treated both by gravity methods and by flotation. It may be said that reciprocating tables are the only means now used for slime-treatment. These tables give excellent results for the treatment of material within their range of efficiency, as a table should make a satisfactory saving of galena in sizes coarser than 300 mesh and also do excellent work on the under-size of 300 mesh. A test on a slime-table treating the overflow of classifiers showed the following results: In the feed to the tables, 94% of the lead was through 200 mesh. The resulting concentrate assayed 76% lead, 89% of the concentrate being through 200 mesh. Of the tailing loss, 98.5% was through 200 mesh and the screen-

analysis showed this loss to be with minus 300 mesh. The recovery was 65%. When flotation was introduced, the tendency was to eliminate the slime-tables and to treat the entire slime-tonnage directly by flotation, but the pendulum is now swinging back, which is the logical course. The usual practice now is to table as much of the slime as possible. The slime-tables never make a finished tailing, the material in every case being treated by flotation, but tabling has served to lower greatly the grade of the flotation-feed. Table-treatment serves to yield a concentrate very much cleaner than is possible with flotation, while the smelting charge on the table-concentrate is lower and the tonnage shipped is less than if the slime had been treated directly by flotation. Some of the plants send the overflow of the de-slimes apparatus direct to the flotation-plant, but such a method means a rich feed. Other plants settle the classifier overflow and give it a table-treatment, and by this means at least 65% of the lead is saved in the form of a table-concentrate, assaying fully 75% lead. One plant is even re-treating by further tabling the middling from the slime-tables. Another, by careful slime-table treatment, is sending a feed to the flotation-plant containing but 2.25% lead, which feed, before treatment by slime-tables, contained 6% lead.

The Federal Land Co. did the pioneer work in this district on flotation, and it solved the problem of floating the fine galena after it had been considered impracticable. This company had the first operating flotation-plant, and knowledge there gained was freely given to other operators in the field, so that now flotation-plants are found at every mill in the district. Roughly, the flow-sheet used is as follows: The slime is settled in Dorr tanks, the spigot-product, containing 1 part of solid to 4 of water, is treated in flotation-machines, with crude wood-creosote as the frothing-agent. No acid is used. The concentrate is a finished product, while the tailing is treated on tailing-machines. The introduction of flotation has not greatly altered the metallurgy of the ores. Flotation is not replacing gravity concentration except for the very fine sizes, and economically never can. Fortunately the physical nature of the ore is such that an economic tailing can be made on the jigs and tables, and this fact precludes the possibility of flotation ever encroaching upon the field of gravity concentration. The logical field of flotation here is the treatment of galena finer than 300 mesh, as efficient work can be done with tables on coarser sizes than this. It will thus be seen that the field for flotation is sharply defined, being limited to the treatment of slime-products only, no attempt being made to displace gravity concentration by flotation on the sizes coarser than 200 mesh.

SCHEELITE is preferred by smelters of tungsten in this country, and therefore it commands a superior price to wolframite and hübnerite. The reverse is the case in England, where the iron tungstate holds a more favorable position in the market.

# REVIEW OF MINING

## LEADVILLE, COLORADO

### IRON PYRITE PROSPECT.—MANGANESE MINES.

A. S. Harvey of Los Angeles has secured an option to purchase for \$50,000 eighteen placer-claims comprising 2100 acres in the Arkansas valley 10 miles south-west from Leadville. He plans to construct a dredging plant on the ground that will cost \$50,000. The ground has been held by Lake county for several years for delinquent taxes which total approximately \$50,000. Construction on the dredging plant will be undertaken early next spring and will be completed before the end of the year. Examination during the summer resulted in the finding of good ground. Mr. Harvey, who is a former Leadville resident, will have D. A. Cannon and others associated with him in the enterprise. The dredge will be the second to enter Lake county; the boat now operated by the Derry Ranch Gold Dredging Co., a mile north-west from the new site, is the only one in the district.—Because of the huge sum owing to Lake county in back taxes on mining property, the Board of County Commissioners has instituted a new plan that is expected to result in the payment of a large proportion of the delinquent money. The board has decided that offers to purchase property for back taxes, or a part of them, will be considered and accepted under the same ruling now governing real estate. Heretofore no reduction on taxes due on mining claims would be made by the commissioners, and the result is that the county is out several hundred thousand dollars. Under the new plan, it is believed that numerous offers will be made to secure title to old claims for a fair part of the taxes now due on them, thereby enabling the county to realize a portion of the money already owing and at the same time place these redeemed claims in the active assessable property of the county. The new ruling is also expected to cause an increase in development and be of general benefit to the entire district.—Leadville mines containing iron pyrite with a high-sulphur content are soon to have a good market for their ore, according to Gustavus Sessinghaus, a Denver mining engineer. For several years, Mr. Sessinghaus has been engaged in the purchase of ores used in the manufacture of chemicals; and he is an authority on the subject. In the Leadville district there are several large mines in which extensive deposits of pyrite have been opened. These bodies are practically free from any metals that would make them valuable and therefore have remained undeveloped for years. The Ixex on Breece hill, the Adelaide in Adelaide park, the Louisville, Moyers, Tucson, and R. A. M., on Iron hill, the Greenback in Graham park, and several properties developed through the Yak tunnel have large deposits of pyrite uncovered in the lower workings within easy access to development. Mr. Sessinghaus states that a considerable tonnage could be extracted from these properties without delay. A slight reduction in the freight-rate on pyrite between Leadville and Eastern points where the ores are used will help local production, and an effort is now being made to have pyrite classed with low-grade lead and zinc ores. It is stated that this change in rating would be sufficient to make mining of pyrite from Leadville mines profitable.

The production of manganese in the Leadville district is rapidly becoming an important factor. Recently several large

bodies of ore averaging from 30 to 40% manganese have been discovered, the two largest being at the Grey Eagle and the Bohen properties on Carbonate hill. In the former, two large shoots of the ore have been opened, showing the material to contain 30 to 38% manganese, 1 to 6% silica, and 21% iron. At the Penrose, Northern, Seneca, and Nisi Prius, new bodies of manganese have been discovered, and there are a number of big deposits opened at the Star properties. A slightly better market will cause a heavy tonnage of this ore to be shipped from the district.—The latest strike of importance is that at the Hayden shaft on the May Queen and Hibernian claims on Yankee hill. The May Queen Leasing Co., headed by David Harris and P. C. Madscen, has opened a body of zinc carbonate that ranks with the big discoveries made at the Wolfstone several years ago. A shoot 110 ft. long, 29 ft. high, and 20 ft. wide has been opened from the 150-ft. level of the shaft. The ore averages 26% zinc. Development in the shoot still continues and the limits of the ore have not been reached.

M. J. Nicholson, superintendent of the Western Mining Co., operating through the Wolfstone shaft on Carbonate hill, states that for several days the property has not been shipping its normal output because of the car-shortage. Large storage-bins have been erected on the surface to hold the ore when it is impossible to secure the necessary cars. In this way the property has maintained normal development. Mr. Nicholson admits that the problem is becoming serious, and that it may be necessary in the near future to reduce operations at the Wolfstone, as it has been at other properties.

## ELY, NEVADA

### A SURVEY OF THE DISTRICT.

The Nevada Consolidated is running at full capacity; it, as well as the railroad, is having trouble to secure sufficient coal for current demands.—The Copper Mines Co. has almost 700 men on its payroll; it is doing a large amount of surface work and erecting buildings and new machinery.—Development work is proceeding at the Alpha from the Giroux shaft.—The Ward mine, 18 miles south of Ely, is having difficulty in transporting its ore. A large amount of ore is ready for shipment but the company is unable to get it to the railroad, 60 tons per day being all that it is possible to move. A narrow-gauge railroad seems to be the only solution to the difficulty.—Williams & Thayer shipped a carload of carbonate ore from the Robinson district; it is expected that it will run 40% zinc.—The Hamilton district is making a better output than for many years past; a large amount of ore is sacked and piled up at the various mines, but it is impossible to secure teams or trucks. Truckage to Kimberley, 35 miles away, costs \$16 and to Eureka, about the same distance but with less grade, \$14.

The old camp of Eureka is showing some life. Julius Huebner, in charge of the California, is adding a compressor and a boiler. Some Salt Lake people leased an undeveloped piece of ground last spring and are making shipments of ore running \$150 in lead-silver. They have an excellent showing.—It is believed that if the railroad facilities were better, the camp might return to its old-time prosperity, but it is impossible to handle any tonnage. Only a few properties are

working at or near Austin. Eastern people have an option on the old Austin Consolidated. The mill-records of this mine show a production of almost \$20,000,000, and the deepest workings are only 600 ft.—Salt Lake people have taken an option on the old Ophir silver mine in the Toyaba range. There is a vein of good size, and the old dumps indicate that there have been extensive operations in the past.—The old Jefferson mine, six miles up Jefferson canyon, south of Round Mountain, has been purchased for \$165,000, it is reported, of which \$75,000 has been paid. A new mill has been completed and recently a trial-run was made. Fifty men are employed.—John Seaver is working his silver property, and occasionally makes shipments of good-grade cobbled silver ore.—Berg Bros. of Round Mountain have made a discovery recently. A 12-ft. shaft 6 by 8 ft. has been sunk in solid ore that assayed \$240 per ton.

### PORCUPINE, ONTARIO

HOLLINGER. — MCINTYRE-PORCUPINE. — DOME MINES. — MINING CORPORATION.

The Hollinger Consolidated equipment has a capacity for handling between 2700 and 2800 tons per day as compared to 1700 and 1800 during 1916. During 1916 this company paid \$3,126,000 in dividends; the ore-reserve is several million dollars in excess of what it was a year ago, so it is evident that with anything like an adequate supply of labor this greatest of Canadian gold mines will set a still higher standard of achievement.—The tonnage being treated at the McIntyre-Porcupine is greater than ever before, an average of over 500 tons per day is being maintained. The production of bullion is being maintained at the rate of \$140,000 to \$150,000 per month and the dividend requirements of 5% quarterly, or about \$186,000, is being more than earned. The development at the 1000-ft. level is being pushed forward unrelentingly and, since the estimate of \$5,000,000 in ore-reserve on June 31, a considerable quantity of ore has accumulated.—The decision of the Dome Mines to curtail production during the winter months has caused neither surprise nor alarm. It was made on account of the shortage of labor. In a general way, the mine is in a better condition than ever before. The facilities for handling ore are understood to be far in excess of present mill-capacity. The ore-reserve of nearly \$15,000,000 is sufficient evidence that shortage of ore had no bearing on the decision to curtail milling operations.—At the 600-ft. level of the Porcupine V. N. T., excellent results pertain. The 100-ton mill is running at almost capacity, and the improvement in the supply of labor is being felt in a marked degree at this mine.

Mining companies of Cobalt are producing silver bullion at the rate of approximately \$60,000 per day, as figured on an average price for silver during September. The weight of the output is about two and one-half tons per day or at the rate of 900 tons of silver annually.—Mining Corporation continues to lead all other mines in point of production, while Nipissing easily holds the lead in point of ore in reserve. Nipissing is in the happy position of having considerable ground as yet unexplored. Mining Corporation is carrying out a policy of acquiring additional property, having taken over the Waldman about two weeks ago and only this week it has purchased the old Alexandra property, situated near the Bailey Cobalt.—In the lower levels of the Chambers-Ferland mine, the results continue to be satisfactory. Some fairly high-grade ore is being found just above the contact, and considerable low-grade ore is being broken.—The sinking of a winze at the 1600-ft. level of the Beaver Consolidated, the deepest working in the Cobalt district, is going ahead with highly encouraging results and, owing to its bearing on other properties, is commanding a great deal of attention.—The profit from the Cobalt mines for 1917 will probably compare favorably with the banner years of the camp. The output for the year will agree-

gate at least \$15,000,000. The annual payroll, due to the high wages and large bonuses being paid the mine-workers, will be not far short of \$4,500,000, while the cost of material will be about \$3,000,000, thus making in all about \$7,500,000 for operating expense and leaving a net profit of about an equal amount. In view of the high price of supplies and cost of labor the showing made is extremely satisfactory.

### TONOPAH, NEVADA

TONOPAH EXTENSION.—TONOPAH BELMONT.—WEST END CON.—DESERT QUEEN.

Last week the Tonopah Mining Co. produced 2850 tons of ore. In the Silver Top 123 ft. of development was done, in the Mizpah 21 ft., and in the Sandgrass 111 ft., making a total of 255 ft. On the 240-ft. level of the Silver Top stoping continues on a 3-ft. face on the Valley View vein, while on the 440-ft. level the vein is only 2 ft. wide. On the 540 and 640-ft. levels the Burro vein shows a 3-ft. face, as does the South Dipping vein. On the 1440-ft. level of the Sandgrass the raise in the Upper Sandgrass vein shows about 4 ft. of ore.—The Tonopah Extension Mining Co. shipped 20 bars of bullion valued at \$40,000, representing the clean-up for the first half of October. In the No. 2 shaft 95 ft. of development has been done, and 125 ft. in the Victor. In the No. 2 shaft, cross-cut No. 510 on the 1350-ft. level cut the Merger vein, exposing 4 ft. of ore. At the Victor on the 1440-ft. level, the Murray vein is being stoped on an 8-ft. face. Raise No. 1503 on the 1540-ft. level continues in mill-ore. On the 1680-ft. level development in the south cross-cut shows the Merger vein, recently intersected, to have a width of 6 ft. Cross-cutting has been delayed in order to cut a pump station to handle the excess water. The production for the past week was 2380 tons.

The Tonopah Belmont Development Co. shipped 37 bars of bullion from the Belmont mill and 23 bars of bullion from the plant at Millers. The shipment represented the bi-monthly clean-up and was valued at \$104,684. On the 700-ft. level, raise No. 5 from No. 760 west cross-cut reached the faulted segment of the South vein, exposing 3 ft. of fair ore. Raise No. 6 on the Mizpah Fault vein has a full face of fair ore. The east drift on the 1166-ft. level on the Mizpah Fault vein is being driven on a 2-ft. face of good ore. The last week's production was 2491 tons.—The West End Consolidated Mining Co. continues to push development on the Ohio vein. Drift No. 531 continues in high-grade ore and drift No. 555 cross-cut No. 1 also maintains its excellent showing. Stoping on the Ohio vein furnishes a large tonnage of good ore. At the West End shaft No. 717 drift No. 2 continues to make good progress and raise No. 677 has reached the foot-wall of the vein. The output the last week was 1118 tons.—In the Desert Queen section of the Jim Butler Tonopah Mining Co. unfavorable mining conditions have caused a discontinuance in the development of the Ophir King on the 900-ft. level. Development has been resumed in an upper level. At the Desert Queen shaft on the No. 625 intermediate, a cross-cut has been started toward the vein on the South fault. The production for the past week was 1050 tons.—The MacNamara Mining Co. has commenced development on the 725-ft. level. Drift No. 18 shows a 2-ft. face of fair ore and the north drift has a full face of fair ore. Stope No. 2 above the 200-ft. level shows 5 ft. of ore. Stoping continues in the 300-ft. level in stopes No. 1 and 4. The production the past week was 406 tons.—The Cash Boy Consolidated Mining Co. intersected the foot-wall branch of the vein, which is about 6 ft., on the 1700-ft. level. Driving will be started on the hanging-wall branch of the same vein. The output for the past week was 55 tons.—Last week the Rescue-Eula produced 128 tons, the Montana 53 tons, and miscellaneous 47 tons, making the week's production at Tonopah 10,578 tons with a gross value of \$185,115.—At the Silvermines Corporation at Hornsilver a station is

being cut on the 500-ft. level of the incline shaft to facilitate development of the large orebody exposed at that point. A new ore-shoot has been found to the west of the 400-ft. level station.

### MANHATTAN, NEVADA

WHITE CAPS.—UNION AMALGAMATED.—MANHATTAN  
CONSOLIDATED.

The east orebody of the White Caps has been opened up from both the fourth and fifth levels. On the fourth level the orebody has been proved to have greater dimensions between walls than was known previously, and on the fifth level it is found to be longer than on the one above. As shown on the upper levels the orebody is continuous up to the east fault where it is cut off. This fault will not be reached on the fifth level until 120 ft. has been driven along the course of the ore. So far there has been no development work to demonstrate the width of the east orebody on the fifth level, the drift being run along the foot-wall. During the past week 35 ft. has been added to the east drift on the ore. Already the east orebody has been exposed for a length of 115 ft. and when continued to the fault mentioned it will have a demonstrated length of at least 235 ft. The car samples for the past three days have run \$28, \$53, and \$56 per ton. A sample taken close to the foot-wall showed \$80 in gold. On the fourth level the east sill is being put in ready to start stoping operations, by the shrinkage system. The cut being made across the ore for the sill-floor has now been extended 32 ft. and neither wall shows as yet. The foot-wall is known to be back at least six feet beyond the sill-floor and the hanging wall will be at least as far, so it is safe to state that at this point the east orebody is 45 ft. between the walls. The ore exposed in the present work has a higher average value than that shown in the drift originally run along the east orebody. On the third level, the east drift from the foot-wall cross-cut has been extended 11 ft. during the week, making a total of 27 ft. It has now been discontinued, as the stoping operations from the fourth level will make use of the waste rock from this drift for back-filling after connection is made. From the fifth level the west cross-cut has been started to extend to the shaft orebody. The White Caps hoist-house is being connected with the various levels by flash and electric-bell system, and a mine telephone is being added. The bunk-house for the White Caps employees will shortly be completed.

During the week the Manhattan Consolidated has had 45 ft. added to the length of the east drift from the fourth level, the face now being 200 ft. from the shaft. The east orebody should be cut within another 50 ft. From the third level the south cross-cut has been extended 25 ft. for the week, only one shift being employed. A decided change is showing in the face of the east drift from the 400-ft. level. Although too soon to be sure, probably the mud fault has been encountered.

The development for the week to October 24 at the Amalgamated is as follows: from the 600-ft. level the raise on the fissure vein has been advanced 20 ft., making a total of 41 ft.; the shaft cross-cut has been advanced 32 ft. The raise on the fissure has cut across the Mushett ore-shoot for 25 ft. with no hanging wall in sight as yet. Owing to the present programme of the company to stop all development and concentrate the full force on the enlargement of the Earl shaft and connect same with the present bottom level of the mine, the fissure raise will not be advanced any further at present. The shaft cross-cut is now directly under the Earl shaft, but will be extended an additional eight feet before the raise is started, to allow room for an ore-chute. When this is in place a raise the full width of the shaft will be put up to connect with the Earl shaft at the 350-ft. level. Work in straightening and enlarging the Earl shaft is proceeding favorably. The surface equipment at the Earl has been placed in first-class condition

and the shaft has already been enlarged to a full two-compartment shaft for a distance of four sets below the surface. Three shifts will be employed in this work and it will be pushed forward with all expedition now that the preliminaries are finished. The Amalgamated mill is employed on ore extracted during the recent development work in the Earl orebodies. The mill is to be dismantled when this has been completed and it will be re-erected on Litigation hill close to the collar of the company's permanent working-shaft.

### CHLORIDE, ARIZONA

A GENERAL SUMMARY OF THE DISTRICT.

The greater number of the operating mines in Chloride are situated in the main range, east of town. The ores contain silver, lead, zinc, and copper, together with a little gold. To the west of town, the gold content runs higher, and lead and zinc are less prominent.—The Tennessee mine, which is practically in the town of Chloride, is being worked to a depth of 1600 ft. It has been a producer of lead-zinc ore for many years and at the present time is shipping 150 tons per day to the concentrator at Needles.—The Schuylkill mine, operated by Frank Garbutt of Los Angeles, is being actively developed and has a large amount of high-grade lead ore blocked out.—The Elkhart mine and the Elkhart Extension have been shut-down.—The Chloride Queen group is in operation and showing good ore.—The Hercules property is in active operation with a good crew.—The Schenectady, operated by the Telluride & Chloride Mining & Leasing Co., has developed a large body of rich silver-lead ore.—The Bullion Hill mines are in course of development; an electric plant has been erected.—The New Tennessee is working a full force.—One of the most notable properties of the district is the Copper Age, operated by the Arizona Ore Reduction Co. This is undergoing extensive development and a modern mill is being erected.—The Hidden Treasure, belonging to the Chloride Mining Co., is shut-down, pending re-organization.—The Emerson property, operated by E. M. Bind, is working a small crew of men; it is expected that ore-shipments to the Steffy custom mill will be made shortly.—A 300-ton flotation plant has been erected at the George Washington group. This mine was purchased recently from the Moyle brothers.—A 50-ton flotation plant was constructed last year at the Keystone Con. M. & M. Co., and has recently been re-modeled by Charles Sherman, the superintendent, with satisfactory results. Mr. Sherman is testing this mill upon low-grade ores from the old dump, and is concentrating about 50 tons into one, making a high-grade flotation-concentrate that carries about 5% of copper, together with silver and gold. The operation is interesting from the fact that the raw ore contains only 0.2 to 0.3% of copper which is nearly all saved by flotation.

To the west of the town of Chloride the Puzzle group is in active operation under John J. Robertson, for the New Mohawk Mining Co. The Mohawk Mining Co., an Eastern corporation which lately took over the old Puzzle, Moose, and Columbia groups, has done considerable development at each mine.—The Diana, under management of George F. Beveridge, has developed some high-grade gold and silver ore.—The Jamison, owned by Coeur d'Alene parties, is making good on the east and west drifts of the 300-ft. level; the vein is 6 ft. wide and has a value of \$15 per ton.—The New Jersey Mining Co., E. Mingle, manager, is working on a big body of gold ore.—The orebody of the Emerald Isle Copper Co., near the entrance to Mineral Park canyon, is mainly a silicate and carbonate of copper; it is opened to a depth of 25 ft. by pits and shallow shafts, and assays 2.75% of copper. The ore is treated by a leaching process and the copper is recovered electrolytically.—The Union Metals Mining Co., to the south of the Golconda, is developing a lead-silver-gold ore having a value of \$50 per ton. A cross-cut to a second level has cut

a vein of silver-lead ore. Occasional shipments are being made to Selby. J. P. Ryan, of Chloride, is the superintendent. The face of the 600-ft. adit on the Mary Bell mine on Cerbat mountain, owned by J. P. Ryan and others, shows 20 in. of dense sulphide ore. It is proposed to open this mine to an increased depth of 500 ft. by driving from the same lode in the Payroll mine.

## MAMMOTH, UTAH

TINTIC SHIPMENTS.—IRON BLOSSOM.—CHIEF CONSOLIDATED.

For the week ended October 19, the shipments of first-class ore from the mines of the Tintic district totalled 203 carloads. These are estimated at 9500 tons, and valued at \$250,000. This is compared with 172 carloads the previous week. The temporary lifting of the embargo on ores had the effect of increasing the weekly tonnage by 31 carloads. The camp is now in shape to add largely to these figures if cars can be secured and the smelters will accept all the ore the mines are capable of producing. The principal shippers this week were: Dragon Con. 45 cars, Mammoth 30, Iron Blossom 25, Chief Con. 23, Centennial-Eureka 15, Gemini 14, and Colorado Con. 14 cars. The combined shipments of the other mines was 37 cars, making a total of 203.

Preparations for extensive mining operations are progressing favorably at the property of the Tintic Drain Tunnel Co. on the slope to the south-west of Elberta and it will not be more than a few weeks before the new compressor is running. The machine is being placed on its foundation, and material for the line which will give the Tintic company electric power has been received. The company has six new buildings and a large amount of timber and other material on the ground. Miners are already busy enlarging the face of the adit and placing it in shape for fast work when air is available for the drills. This new corporation was formed by Jesse Knight and associates for the purpose of driving an adit into the south end of the Tintic district to drain the Knight properties and other mines at a depth of more than 2000 ft. This undertaking will require years of labor and the expenditure of a large sum of money, but the matter has been investigated by Mr. Knight and there is no doubt but that it will be carried to completion. The local mining paper states that "The local officials of the Knight mines are unable to account for the recent slump in the price of Iron Blossom stock unless it can be attributed to the lighter shipments, due to the smelter embargo and car shortage, and a corresponding decrease in the mine's earnings." An official report from the office of the Iron Blossom company at Provo states that the treasury contained more than \$160,000 when the directors were in session last week and the recent \$50,000 dividend was declared. This is not a bad showing when it is understood that every mine in this district has been forced to slow down during the past few months, none being allowed to move its regular amount of ore. Stories that the Iron Blossom would hardly be able to continue the payment of dividends are ridiculous. It is true that the heavy shipments of the past few years have materially decreased the mine's ore-reserve but there is quite a long life ahead of the property even if no new ore is found, and in Tintic the only mines that fail to find new ore are those that limit development work. There has been a slight improvement in the car situation during the past few days, so far as the Knight mines are concerned, and the Dragon is once more sending out a large tonnage, this fluxing ore being in demand at the various Utah smelters. At a recent meeting of the directors of the Chief Con. M. Co., a 10c. dividend, or approximately \$88,000, was ordered to be paid. This is the regular 5c. dividend and an extra dividend. Books will be closed to the transfer of stock on October 20, and the dividend checks will be in the hands of the shareholders on November 5. This dividend will bring the total up to \$747,784.—In 1913 the Mammoth Mining Co. paid under

protest a tax of \$43,214.58, levied by Juab county on a dump, the material in which was taken out of the mine between 1876 and 1890. The appeal is now before the Supreme Court.

A contract has been let for sinking the No. 1 shaft at the Iron Blossom from the 1000 to the 2100-ft. level. It has been some time since the Iron Blossom company did any development work on the 1900-ft. level which is the lowest point in the No. 1 workings. The vein had been cut there, however, and owing to the fact that the limestone on the 1900-ft. is silicious the management has decided to sink a couple of hundred feet, in the hope that a less silicious limestone will be found. Two men, Dan McKenzie and William Sharp, lost their lives in the No. 1 shaft of the Iron Blossom mine on October 25; their bodies being blown to pieces by the explosion of a round of holes that they had just loaded; they were lighting at the time of the accident. Both men were experienced miners and it is hard to understand why they remained in the shaft until the shots went off. The Iron Blossom shipped 21 cars of ore this week; the shares sold at 65c.—At a stockholders meeting of the Golden Key, held at Provo on October 29, the company's property was sold to Jesse Knight for \$1500. It consists of two claims in the Tintic mining district on the course of the Knight Tintic Drain Tunnel, the owners of which will take it over. The Golden Key has ceased to exist; the stockholders will be paid about one cent per share on the capital stock.—A winze is being sunk from one of the drifts in the Zuma mine on the 500-ft. level where the ore had been followed for nearly 100 ft. While this winze has been sunk but a short distance there has been improvement in the showing.—Local people have organized the Eureka Metallurgical Co. and it is understood that they are planning to erect and operate a custom milling plant similar to the Argo, Canyon City, Colorado. R. V. Smith, one of the well-known metallurgists of the State, is working out the process to be used; flotation will be one of the chief factors. Mr. Smith has secured patents on several new features which will be used in the plant. The company at present has a small experimental plant near the Bullion Beck mine and the tests made at this plant have been satisfactory. The company is capitalized for \$50,000 divided into shares of the par value of 10c.; the officers and directors are: M. A. McCrystal, president; R. V. Smith, vice-president; Edward Pike, secretary; Thomas McCormick, Jr., treasurer, and A. W. Larson. All of the incorporators are residents of Eureka.

The Chief Con. mine is marketing little or no ore as a result of the embargo and the shortage of railroad cars, but there will be no suspension of development work. For several weeks the Chief has been able to ship a limited amount of lead ore, notwithstanding the fact that the smelters had placed an embargo on the dry ore from this mine, but early this week the United States Smelting company served notice that its plant was overstocked with lead ore and that no more would be accepted. This leaves the mine in a rather bad predicament with a market only for a limited amount of dry ore at the International smelter, at Tooele. In addition to the development work in the main portion of the Chief, this company is spending a lot of money on new work at its Homansville tract at the Plutus. The old Plutus shaft has been re-timbered and equipped with the necessary machinery and the workings on the 400-ft. level are receiving attention. The drifts were in bad shape and it has been necessary to remove a lot of caved ground and put in new timbers. The present plans call for some new work on the 400-ft. level of the Plutus before sinking the shaft below this point. According to N. W. Roberts, superintendent of the Iron King, everything will be in shape for sinking the new shaft within a few days. Men are engaged in enlarging the raise which connects the adit with the surface; this will be the upper part of the company's new working shaft. Sinking will be started from the adit-level below the raise; temporary machinery will

be placed in the adit.—The Ohio Copper flotation mill at Lark is handling between 2000 and 2500 tons of ore per day. The concrete foundations for the enlarged plant are all in and the machinery is on the way. The first units of the flotation plant are giving satisfaction. It is expected eventually to have all the ore finally treated by the flotation process, which is said to be giving about 85% recovery as compared to 40 to 50% in the old mill.—The directors of the Mammoth moth on November 2 declared another dividend of 10c. per share, which calls for the sum of \$40,000 to be distributed on November 8. The books will close on November 3, and re-open on November 8. This will bring the 1917 distribution up to \$1 per share, and the total distribution to \$2,820,000. The Mammoth shipped 36 carloads of ore in October, 33 in September, 73 in August, 80 in July, and 399 in the first six months of this year.

### HOUGHTON, MICHIGAN

NEW CORNELIA.—ADVENTURE.—QUINCY.—ISLE ROYALE.

After an investment of practically \$15,000,000 New Cornelia, controlled and managed by the Calumet & Arizona, has become a profitable producer. While it has yet to pay back the money invested, it gives every promise of success, and illustrates the way Calumet & Arizona interests do big things. The production of copper from this property for October will approximate 3,000,000 lb. The output for the past four months follows: June, 1,318,896; July, 2,267,328; August, 2,130,090; September, 1,608,850; making a total of 7,375,164. The falling off in September was due to a combination of circumstances, all of which were overcome before the first of October. Two kinds of ore come from the New Cornelia, one requires to be leached and the other to be smelted. The copper recovered by leaching during the last four months amounted to 6,739,162 lb., while 646,002 lb. was recovered by smelting. The Calumet & Arizona owns 76% of the stock in the New Cornelia. Six weeks ago the Ajo Consolidated was acquired by a stock payment. The outstanding first-mortgage bonds amounting to nearly \$4,000,000 are owned, practically all, by the shareholders of the New Cornelia. The management believes that 40,000,000 tons is a conservative estimate for the low-grade ore in the New Cornelia. An estimate is made that 20,000,000 tons were acquired by the absorption of the Ajo Consolidated. Practically all of the New Cornelia is low-grade steam-shovel ore. There have been irregular shipments of 3% high-grade that goes directly to the smelter. The company has created a world-wide market for old tin cans and is advertising for them all over the country, paying \$15 per ton for the old tin plate. These cans, together with old iron scrap, are used as a precipitant of copper from part of the solution. Tin cans used in this apparently ludicrous manner secured 160 tons of copper last month.

The application of the Government's plan for price fixing for munitions of war has operated in the Lake Superior copper district with unfortunate results in but one case. The suspension of operations at the Adventure property was caused directly by the fact that with copper at 23½c., it is impossible, with its limited operations, for the mine to work at a profit. The suspension of work at Adventure is unfortunate as the grade of the ore was improving in nearly all directions.—The richest ore-shoot ever opened at the Quincy is on the west vein at the 65th level. Masses and barrel work, some running to pieces weighing ten tons and necessitating special apparatus to handle them underground and at the shaft, are being found. This comes from a vein 60 ft. wide; it is opened on the strike for nearly 100 ft. and continues in richness, practically all of the rock going directly to the smelter.—Nothing more is heard of the \$54 price that was advertised as the figure the Calumet & Hecla intended to pay for the outstanding Isle Royale stock. The impression, created at the time the rumor

was given publicity, that it was put out for stock-market purposes, continues to prevail here. In the meantime the general condition of the property indicates that its intrinsic worth is greater now than at any time in its history, both as to possible earnings and future possibilities as shown by its newer openings.—Despite passing the dividend Mass Consolidated will increase its production in October and November. Shipments have been increased 150 tons per day during the past few days and now average 700 tons.

### TORONTO, ONTARIO

MINERAL SEPARATION.—COBALT SHIPMENTS.—NEW DISCOVERIES.

Complaints are being heard that the Canadian government is slow to investigate the validity of the patents of the Minerals Separation North American Corp., covering the flotation process. This is only to be expected, as the Government is being re-organized by the admission of several Liberals to office, thus forming a Union in place of a Conservative administration and involving a general re-distribution of portfolios. Hon. Martin Burrell, formerly Minister of Agriculture, becomes Secretary of State and Minister of Mines, in place of Hon. Arthur Meighen. As a general election will be held on or about December 19, the Government will be fully occupied with important matters, so it will not be surprising if action in connection with the claims of the Minerals Separation Corporation is delayed considerably. While not abandoning the accusation that the corporation is under German control or influence, the Cobalt mine-owners are basing their case mainly on the ground that the process as covered by the patents is not suited to Cobalt ores and was only rendered available through modifications made by Cobalt metallurgists.

Cobalt ore-shipments for September exceeded all previous records with a total of 4,737,811 lb.; this included 59,100 lb. from the Miller-Lake O'Brien. The heaviest shipper during the month was the Nipissing with 1,830,000 lb. During September the Nipissing mined ore of an estimated value of \$349,258 and shipped bullion from its own and custom ores of an estimated net value of \$346,948.—The Mining Corporation of Canada, which has been re-organized, so as to make it distinctively Canadian, the largest portion of the stock having formerly been held in England, has recently made remarkable progress. On September 9 it had a balance at the credit of profit and loss of \$3,519,768 as compared with \$2,447,582 on December 1, 1916, and the cash in the bank amounted to \$1,338,117, an increase of \$491,750. Two dividends, aggregating \$933,778, have been paid during the current year.—The Kerr Lake is being re-organized by the formation of a new company under the laws of Canada, with the same capitalization as the old company. This is done in order to escape double taxation, as at present the company is liable for taxes in the United States as well as in Canada.—At the McKinley-Darragh development work is being done on the 400-ft. level of the Cobalt Lake fault vein. A width of six feet of low-grade ore has been shown along a 40-ft. drift. The La Rose has sunk 160 ft. on the Violet property, with the expectation of cutting a rich vein coming in from the O'Brien, adjoining. At the Beaver the high-grade vein found on the 1600-ft. level is showing improvement. It has been stoped for 100 ft. and a winze is being put down.

The number of laborers available for the Porcupine mines is steadily increasing as the result of the high wages paid and the return of workers from the harvest fields. The Hollinger Consolidated is pushing development on the Miller-ton property with highly encouraging results, the large ore-body, which was low-grade on the surface, becoming high-grade on the 200-ft. level. The Acme is being worked on the 800-ft. level with satisfactory returns. At the Dome the development drift run on the 700-ft. level to cut a new ore-body approximately 119 ft. wide, indicated by diamond-drilling,

has passed above the deposit. Another drift will be run on the 800-ft. level to strike it.

An important discovery has been made in the Kirkland Lake district by the cutting of a vein 15 ft. wide in the 340-ft. level at the Kirkland Elliott. This mine is situated in the extreme western section of the camp and the find proves the extension of the mineralized area further than was previously known. At the United Kirkland the shaft is down 25 ft. with the vein showing a width of four feet. Operations at the Wright-Hargraves have been retarded by the breaking of the compressor. The new mill of the Lake Shore is expected to be in operation by January. It will have a capacity of 80 tons. The main shaft is down 420 feet.

A gold discovery has been made in Eby township, about three miles west of Swastika. The vein found is reported to be 30 ft. wide, showing considerable visible gold. There are extensive outcrops of quartz in the neighborhood and many prospectors have gone to the new find. Reports of gold discoveries in other localities have obtained currency, but require verification.

## ASPEN, COLORADO

### DEVELOPMENT OF PARK TUNNEL.

The Park Tunnel, Mining & Milling Co. has been formed to develop an immense area in the Tourtelotte Park mining district. The company was organized on July 26, under the laws of Colorado with a capital stock of 150,000 shares at a par value of \$1. The officers of the company are Robert Shaw, president; W. R. Foutz, vice-president; Frank M. Yates, secretary and treasurer; these together with William H. Cornwall and Edward Turner form the board of directors. These men have spent more than a year acquiring through purchase and by lease, 20 full claims in the Park district; and are now in possession of a tract that gives them entire control of this rich district. A number of the properties in the combination, including the Camp Bird, Iowa Chief, Edison, Silver Star, Best Friend, Justice, and Jenny Lind, were at one time among the best mines in the Aspen district and are credited with a combined output of \$1,000,000. Prior to the panic of 1893, which closed down nearly all the mines in the Aspen district, there were more than 1000 miners working at the properties in Tourtelotte Park; and scores of four and six-horse teams were engaged hauling the rich silver ore from the mines to the railroad at Aspen. Since then the high cost of transportation for supplies and movement of ore, high smelter charges, and greatly increased cost of production have combined to restrict development in the Park to a few small concerns operating under leases. Now, after 25 years has elapsed since the abandonment of the mines in the Park, several factors important to mining development have placed these old properties on a splendid footing. Great advancement has been made in the scientific treatment of ores, improved machinery has increased efficiency in production, electrical appliances have cheapened the cost of mining, and freight rates and smelter charges have been greatly modified. With silver again commanding a good price, the possibilities of development in this district are exceedingly promising.

The company proposes to develop this large area through an adit with the portal near the head of Keno gulch. Driving 3000 ft. in a south-easterly direction will place the breast directly under the Last Dollar workings and will give the adit a depth of 700 to 800 ft. Cross-cuts are to be driven both north and south from this point to thoroughly explore the ground. From the portal, a tram is to be constructed to the railroad siding near the Newman adit for handling supplies and ore. The Park district was examined in 1897 by J. E. Spurr of the U. S. Geological Survey and his report was published by the Government in 1898. In it he stated that the contact fault in the Last Dollar, Minnie Moore, and Justice is

remarkable for the immense amount of low-grade ore formed along it. The men responsible for the re-opening of this large area are confident that their project will prove to be one of the biggest and most important enterprises that has been launched in the Aspen district for many years.

## CRIPPLE CREEK, COLORADO

### OCTOBER PRODUCTION AND DIVIDENDS.

The production of gold ores by the mines of the Cripple Creek district for the month of October, as compiled from the reports of the mill managers and smelter representatives, totaled 98,297 tons, with an average value of \$10.44 per ton and gross bullion value of \$1,026,933.70.

The labor shortage both in the district and at Colorado Springs, where the Portland and Golden Cycle mills are situated, reduced the output and treatment. The treatment at the several plants was as follows:

Plant and location	Tons treated	Average value	Gross bullion value
Golden Cycle M. & R. Co., Colorado Springs .....	26,000	\$20.00	\$520,000.00
Portland G. M. Co., Colorado Springs .....	10,582	22.20	234,920.40
Smelters, Denver and Pueblo.	2,755	55.00	152,625.00
Portland G. M. Co., Independence mill, Cripple Creek...	38,750	2.04	79,050.00
Portland G. M. Co., Victor mill, Cripple Creek district .....	18,610	2.03	37,778.30
Rex M. & M. Co.'s mill, Iron-clad lease, Cripple Creek...	1,600	1.60	2,560.00
Total .....	98,297	\$10.44	\$1,026,933.70

The October dividends were as follows: Cresson Consolidated Gold M. & M. Co., \$122,000; Golden Cycle M. & R. Co., \$45,000; Portland Gold M. Co., \$90,000; Vindicator Con., \$45,000; a total sum of \$302,000 in dividends.

On November 10 the Cresson Con. and Golden Cycle companies will pay their regular monthly dividends of 10 and 3c. per share, respectively, amounting to \$122,000 and \$45,000.—The Roosevelt tunnel of the Cripple Creek Deep Drainage & Tunnel Co. was advanced 161 ft. during October. The heading is in a dense black syenite and is still in the property of the Rose Nicol Gold M. Co., on the north-west slope of Battle mountain. The flow has fallen to about 5000 gallons.

The Cripple Creek Deep Leasing Co. and F. R. Caley, lessees of the Jerry Johnson mine of the Jerry Johnson Mining Co., produced 8 cars of ore during the month of October. The Deep Leasing company billed out 5 cars and the Caley lease 3 cars. The average value of the first was \$20 per ton with Caley shipping ore ranging from \$30 to \$50 per ton.—Twelve sets of lessees on the property of the Elkton Con. M. & M. Co. shipped 18 cars or about 500 tons of 1-oz. ore to the mill of the Golden Cycle M. & R. Co., during October.—Hahnwald and associates have resumed shipments from the El Paso Gold King mine; the first producer in the west end of the district. New orebodies have been opened up by the lessees at the 1000 and 800-ft. levels.—Carnduff and Duncan, lessees on the Dead Pine mine of the Granite Gold Mining Co., mined and shipped 16 cars of ore of \$16 to \$18 grade during October. The lessees are operating from the 1000-ft. level of the Gold Coin shaft.—The Mt. Rosa Mines Co., recently incorporated, has taken over the holdings of the Rexall Gold Mining Co. which has been adjudged bankrupt. The properties embrace the Mt. Rosa placer on which is situated the town of Victor, portions of the Gold Coin and Spicer veins, the Rosa Lee, Mt. Rosa, and Adams veins. The new company will shortly block out its holdings for leasing purposes.

## ALASKA

(Special Correspondence.)—William Martin of the Alaska Free Gold Mining Co. is in town with the semi-monthly clean-up. The mill is running on high-grade ore that has been discovered recently. Mr. Martin expects to keep operating until November 1 when cold weather will necessitate closing down the mill for the winter. The development of the mine will continue.—The necessity for a central plant that will supply power the year round is being felt in the Willow Creek district. Conditions are ideal for the development of hydro-electric power, and during the past season conditions have been investigated by an engineer representing Colorado investors, who, it is said, are considering the proposition.—George Anderson, who during the past season has been exploiting the Little Gem mine in the Willow Creek district, reports the adit in 65 ft. with six inches of specimen ore. He is displaying a gold button worth \$17 which is the result of a test run of 100 lb. of ore.—The Cache Creek Dredging Co. has 125 tons of supplies at McDougall, which have been brought there by river steamer, and are awaiting transportation to Cache Creek.—Thomas Riggs, Jr., member of the Alaskan Engineering Commission, and who is in charge of the Fairbanks end of the Government railroad, is at Anchorage conferring with the chairman of the commission.

Anchorage, October 15.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—J. H. Hunt & Co. have acquired the old tailing-dump of the Grand Central mine, one of the big producers of the early mining days, one mile east of Fairbanks. This firm will re-treat the tailing as soon as the necessary machinery has been erected. In the meantime a spur track is to be built connecting with the Benson-Nogales branch of the Southern Pacific. The concentrate will be shipped to El Paso or Deming, New Mexico.

Bisbee, October 25.

### GILA COUNTY

(Special Correspondence.)—P. G. Beckett, for several years manager of the Old Dominion mine, has resigned his position and will take another position with the Phelps-Dodge people. W. C. McBride, who has been assistant general manager for the Detroit Copper Co., will succeed Mr. Beckett.—The Old Dominion Copper Co. has offered a \$50 Liberty Bond as a bonus for all employees who remain with them continuously for one year. The bond must be paid for in installments by the employee, and at the end of the year he receives the bond plus the money he has paid and interest.—The New Dominion Mining Co. is shipping several hundred tons of ore per month; considerable new machinery has been added. The present equipment is sufficient to sink 1500 ft. and arrangements are now complete for deepening the 800-ft. shaft. A winze is being sunk in the main sulphide zone, which has been opened on the 800-ft. level. All ore is being shipped to the Old Dominion company.

Globe, October 25.

### MOHAVE COUNTY

(Special Correspondence.)—The Daisell Mining & Milling Co.

of New York has purchased the Twins mine in the district north of Kingman. Two officials are on the ground, making arrangements for active work. A 25-hp. hoist has been ordered and other orders for machinery will be placed as development warrants. It is planned to unwater the old 330-ft. shaft, re-timber it, and commence sinking. It is claimed the old workings contain 6000 tons of known ore.—Active mining operations have commenced at the Merrimac. The power-plant and compressor are working well. Sinking at the new shaft has commenced.—As a result of the find of molybdenum ore in the Tennessee and the Silver Union group, active prospecting is being done on the extension of these orebodies in adjacent properties. Some samples have been taken which run as high as 12.77%.—J. D. Wavvig, Jr., general manager for the Union Basin Mining Co. at Golconda, announces that a new mill, to replace the one destroyed by fire, will be constructed as soon as the design and details have been worked out.

Kingman, October 26.

### PIMA COUNTY

(Special Correspondence.)—Work has begun on the Yellow group of claims close to the Copper Prince property in the Twin-Buttes district. The lease on this property is held by Ross and Tavote of Tucson.—Cross-cutting on the 300-ft. level has proved the orebody at that depth on the Mile Wide Copper Co. in the Tucson mountains. This orebody has been cross-cut at the 100 and 200-ft. levels, and has opened ore so favorable that the power-plant at the Copper King shaft is to be doubled by the erection of a 100-hp. Diesel engine and a compressor. Another 250-hp. engine has been ordered for the Margareta claim, to sink a shaft and open up the original workings.—The diamond-drill hole at the Little Ajo is down 1500 ft. and is still in rhyolite containing native copper. It is expected that the monzonite will be penetrated soon. Another hole will be started as soon as the first hole is completed.—Diamond-drilling at the Arizona Cornelia Mines Co., formerly known as the Pittsburgh, has been discontinued. Two leases are in operation at the Ajo Cornelia, both of which are shipping ore to the Copper Queen.

Tucson, October 27.

### SANTA CRUZ COUNTY

(Special Correspondence.)—The Duquesne Mining & Reduction Co. is shipping about 200 tons of ore per day. This company has sold its steam-power plant to an El Paso wrecking company. Electric power is now being used at the mill.

Nogales, October 26.

### YAVAPAI COUNTY

(Special Correspondence.)—Machine-drilling has started at the Jerome Copper. The adit, now being driven, is in 105 ft., the original work being done by hand. It is estimated that the contact is in 800 ft., the present adit giving 600 ft. of backs when complete.—G. Kingdon, manager for the United Verde Extension Mining Co., reports that owing to the large amount of development work that is being done the shipments of ore have not been increased above 325 tons per day. The main haulage-level is in about 2000 ft. The air-shaft connecting this adit is down 200 ft.—The concreting of the Edith shaft

is progressing rapidly.—Sinking is now going forward at the shaft of the Dundee Arizona Copper Co.—The south cross-cut on the 700-ft. level of the Verde Combination has penetrated the Yavapai schist, well mineralized with chalcopyrite.—The Mildred Mining Co., in the Weaver district, is awaiting labor troubles to be settled before resuming work.—The Arizona Del Rio company will have a drill in operation shortly.—A deal has been closed whereby Nevada people will exploit a tract of 640 acres situated two miles to the north of the China Oil company.—Thomas C. Byrd, of Coal-linga, and M. L. Bryant, of Taft, have secured a section of land. It is estimated that 120,000 acres in this field has been taken up.

Prescott, October 27.

## CALIFORNIA

### ELDORADO COUNTY

(Special Correspondence.)—A systematic investigation of the Placerville fields is being made by Robert G. Hart, to search for rare metals. Near El Dorado a large deposit of molybdenite is reported; the investigator is sampling the deposit. Other sections of the county will also be given attention.—Arrangements are being made to erect a stamp-mill on the Montezuma mine at Nashville, 11 miles south-west of Placerville. The shaft is 1000 ft. deep with levels at every 100 ft. below 500 ft. In former years considerable rich ore was mined near surface. W. J. Loring and George Wingfield are said to be interested in the property. J. C. Heald is principal owner.—The Washington & California Mines Co. is developing a promising group a short distance from the Montezuma. A 5-ft. vein of free-gold ore has been found in the new shaft, and preparations are being made for more comprehensive work.—San Francisco people have taken a bond on the Havilla and are reconstructing the mill.—Seattle capital is financing the rejuvenation of the Martinez property. Large reserves of low-grade ore are exposed.

Placerville, November 5.

### CALAVERAS COUNTY

(Special Correspondence.)—The Buffalo Gravel mine, three miles south of Mokelumne Hill, in Chili gulch, is using electricity to run its entire plant. A Fairbanks-Morse 15-hp. hoist lifts the gravel from a 200-ft. vertical shaft into the mill building. The mill is a 3-stamp triple-discharge Merrill, with  $\frac{1}{2}$ -in. steel-mesh wire screens; from there the ore goes over riffles to a Neil jug, which separates the fine material from the coarse; the fine going to a No. 2 Deister concentrating table, which separates the precious metals and black sand from the gravel. The black sand assays \$1200 per ton, being rich in platinum, osmium, and others of the rare metals. The gravel averages \$2.20 per ton, and its average thickness is six feet; 4200 ft. of drifts and cross-cuts has been driven. At the bottom of the shaft is a Dow electric pump, driven by a 10-hp. motor. Ed. Westbrook, Jr., late of Alaska, is superintendent, and has designed a novel scheme of getting a large body of gravel with the minimum of powder. The bedrock is a soft clay-slate and he proposes to undercut it with a fine jet of water flowing through a nozzle under a 455-ft. head and then break down the gravel from above.

The Fischer quartz mine, five miles east of Mokelumne Hill, has been acquired by San Francisco capitalists, who have assembled material on the ground to commence operations. There is a 110-ft. shaft on the property, and a 60-ft. drift on a pay-shoot, averaging 4 ft. wide and assaying \$9.20 in gold. The building of the head-frame for the shaft is to start on November 1. At present there are four men employed, but three shifts will be put on as soon as the work warrants it.

Mokelumne Hill, October 27.

### NEVADA COUNTY

(Special Correspondence.)—The old Washington district, above Nevada City, is producing considerable gold and chrome,

and has started to yield asbestos. The Washington Asbestos Co., controlled by Oakland capital, has placed 10 stamps of the old 20-stamp mill at the Fairview mine in operation and is shipping high-quality asbestos to Oakland. The mill has been equipped with special separating machinery, making two products. Shortage of water is hampering work, but as soon as the fall rains set in the mill will be operated steadily. John D. Hoff is president and general manager.—At the Columbia Consolidated group 20 stamps are dropping on ore from the Columbia and Ocean Star mines. The product averages over \$10 per ton in gold. At the Ocean Star shaft much new work has been begun. A hoist and other equipment is being erected at the Snow Point, four miles above Washington, and the sinking of a shaft will start shortly. Chrome and gold are being extracted from the Red Ledge. Several chrome deposits are receiving attention and small shipments are being made.—More machine-drills have been placed in commission in the Empire mine and development of new territory is proceeding below the 4400-ft. level. The 60-stamp mill is running steadily, crushing good ore from the Empire and Pennsylvania properties. The monthly gold output is reported to approximate \$100,000.—Suit for \$20,000 against the South Yuba Mining & Development Co. has been filed in the Superior Court by Luella B. Kyle, on grounds that the breaking of defendant's Diamond Creek flume seriously damaged the Eagle and other claims owned by plaintiff. The properties are near Washington.—Mining is quiet around Nevada City, due partly to high cost of materials and labor. The North Star Mines Co. continues to operate the Champion group, and several small properties are working along narrow lines.

Nevada City, November 5.

### SHASTA COUNTY

(Special Correspondence.)—The flotation plant of the Afterthought mine at Ingot is showing good results. In a recent trial 300 tons of ore produced 144 tons of concentrate that assayed 44% zinc and 8% copper. The result exceeds expectations.—A new five-stamp mill on the Sybil mine four miles west of French Gulch is under construction by the Shasta Hills Mining Co. All the machinery is on the ground.—The Noble Electric Steel Co. at Heroult is operating two furnaces on ferro-manganese ore. The output of ferro-manganese is from 10 to 14 tons per day. The alloy is worth \$325 per ton in the markets. G. F. Coleman is the new superintendent. A force of 125 men is employed.—Shipments of ore from the Iron Mountain and Hornet mines, owned by the Mountain Copper Co., are being made at the rate of 1000 tons per day. The company has a full crew; the strike having been overcome.

Redding, November 1.

### SIERRA COUNTY

A verdict for \$100,000 has been rendered by a jury in United States Judge Frank H. Rudkin's court against the Twenty-one Mining Co. in favor of the Sixteen-to-One Mining Co., which sued the former for \$280,000 for gold alleged to have been taken from its vein. The companies operate adjacent properties in this county. In a counter suit, the Twenty-one company asked for \$155,000, declaring its part of the vein had been entered. The trial occupied three weeks. Bert Schlesinger, attorney for the Twenty-one company, obtained a thirty days' stay of judgment, announcing that the verdict would be appealed.

### TRINITY COUNTY

(Special Correspondence.)—The new dredge under construction at Trinity Center for the Estabrook Gold Dredging Co. will be by far the largest one in the county. The hull will be 165 by 70 ft. and the buckets will have a capacity of 20 cu. ft. The company's saw-mill is ripping out lumber for the hull. J. G. Souther is the new superintendent. He superseded G. B. Hodge, who was called by the draft.

Carrville, October 25.

## COLORADO

## TELLER COUNTY

(Special Correspondence.)—The following dividends have been paid by Cripple Creek mining companies: Cresson Consolidated Mining & Milling Co., 10c. per share, \$122,000, monthly dividend, paid October 10. Golden Cycle Mining & Reduction Co., 3c. per share, \$45,000, monthly dividend, paid October 10. Portland Gold Mining Co., 3c. per share, \$90,000, quarterly dividend, paid October 25. Vindicator Consolidated Gold Mining Co., 3c. per share, \$45,000, quarterly dividend, paid October 20.

The Millasier Mining Co., owning and operating the Clyde, on Battle mountain, has reached a depth of 1125 ft. in the main shaft and will sink to the 1300-ft. level.—The Modoc Consolidated Gold Mines Co., operating the Modoc mine adjoining the Clyde property on Battle mountain, commenced shipping this week. Lessees are also making a slight production from the old incline shaft on the Ocean View, from the Bull Hill end of the claim.—A ground tramway has been constructed

berg shaft will soon be in commission, when the production from the property will be materially increased; leasing operations will be carried on through the old inclined shaft.—Lessees of the Elkton Consolidated Mining & Milling Co., John Barnard and associates, have opened up rich ore on the Henley vein, at the third and fourth levels of the main Elkton shaft. A streak about four inches wide assays as high as 25 oz. gold, but the lessees are working about 3-oz. ore.—The output from the Elkton mine for October will total nearly 15 cars, produced by lessees who are also shipping from the Tornado mine on Raven hill.—The Camp Bird Mining, Leasing & Power Co., operating the Rose Nicol mine under a six years' lease, has ceased operations at the 1000-ft. level of the Portland No. 2 shaft, and is confining work to sinking the main Rose Nicol shaft.—The Unity Mining & Leasing Co. is sinking a new shaft on the south end or Raven Hill half of the Nightingale claim; it has attained a depth of 450 ft. On November 1 the manager, H. M. Hardy, will increase the working force to two shifts and will sink to a depth of 800 ft. The Nightingale adjoins the Maggie mine of the Cresson Consolidated G. M. & M. Co., and the Unity shaft is but a short distance from the Cresson main shaft.—The Excelsior M. D. & E. Co. has sunk the Longfellow shaft to the 575-ft. level. This company, previously operating through the Golden Cycle shaft, has ore opened up on two levels that are reached from the 500 and 600-ft. levels of the Longfellow shaft. The property is owned by the Stratton estate.—The annual stockholders' meeting of the Catherine Mining Co. for the election of a board of five directors will be held at Victor on November 13. The company has a lease and bond on the properties of the Last Dollar Gold Mining Co. on Bull hill.

Cripple Creek, October 25.

NEW FLOTATION PLANT AT AFTERTHOUGHT MINE, SHASTA COUNTY, CALIFORNIA

at the Eclipse mine, of the Queen Gold Mining Co., and ore is again moving from the property. The company is controlled by J. T. Milliken of St. Louis, and is a close corporation.—There is a shortage of men in the district.

The net earnings of the Vindicator Con. G. M. Co. for the third quarter of the year totaled \$49,000, according to the statement of G. S. Wood, the president, in a circular letter addressed to stockholders and mailed with the checks for the October dividend. The reduction in earnings, as compared with the first two quarters of the year, was due to the increased cost of supplies and of labor in the district. Leasing operations, too, from which the company has derived a substantial income, have been largely curtailed for the same reason.—A drift has been started from the Roosevelt Tunnel level, to prospect the Funeral or Anna Lee dike, and is being carried north-west through the Big Banta claim of the United Gold Mines Co., toward the main shaft of the Cresson Consolidated G. M. & M. Co. This dike has produced heavily in the Portland estate to the south-east. The heading of the adit is still in the Rose claim of the Rose Nicol G. M. Co. on the north-east slope of Battle mountain, and is in hard syenite.—The Modoc Consolidated Mines Co. has been loading ore of \$25 to \$30 grade during the present week, from the old inclined shaft workings. The ore was taken out in course of development at the 11th and 15th levels. The new vertical Franken-

## IDAHO

## SHOSHONE COUNTY

The interest of the Bunker Hill & Sullivan in the Star-Morning case was frankly disclosed by Stanly A. Easton, the manager, during cross-examination on November 2. Mr. Easton on direct examination told of his investigation of the properties involved, and expressed the opinion that the apex is along the lode crossing the Morning and Evening Star claims. On cross-examination he was asked if the Bunker Hill & Sullivan was not interested in the outcome of the case at bar. Frankly stating that it was, Mr. Easton explained that the Federal Mining & Smelting Co. was a subsidiary of the American Smelting & Refining Co., which sought to control the lead ores of the district; that if the Federal company was permitted to mine the ores from the Star property, that tonnage would be diverted to the A. S. & R. Co., which was even now attempting through action at bar to control the Bunker Hill & Sullivan tonnage, and to prevent treatment of that tonnage in the company's own smelter.

## MONTANA

## LEWIS AND CLARK COUNTY

(Special Correspondence.)—Marysville and Bald Butte, which are practically one district, are both looking well. New ground is being developed at the old Bald Butte mine, west of the main range from Marysville. The old mine was worked to a depth of about 600 ft. when the ore appeared to run out and work ceased. Since then good ore has been found in a

parallel vein, 700 ft. south. To open this vein at depth a cross-cut is being run from the old shaft at 400 ft. The cross-cut has been driven 500 ft. through extremely hard rock by hand-drilling; this work is to be concluded with air-drills. A compressor driven by electric power has been erected. A shaft is being sunk on another vein, two feet wide, south-west from the main shaft.—The St. Louis is milling ore from old stopes in the Drumlummon mine.—The Barnes-King is working the Shannon orebodies at the head of Rawhide gulch.—A new 300-ton electrically-driven ball-mill has been erected at the Porphyry Dike, replacing a 20-stamp mill.—The Helena, Cruse Con., and Rock Rose are shipping galena ore from Grass Valley.

Helena, October 28.

#### SILVER BOW COUNTY

(Special Correspondence.)—It was announced yesterday in Boston that the Goldsmith mining claim, one of the early silver producers in the Butte district, was purchased by the Crystal Copper Co.; the deal having been consummated on October 23. The Goldsmith claim is in the north-western part of the Butte district; it consists of 17 acres, and is credited with a production of \$1,500,000 in silver from ore extracted above the 367-ft. level. The silver occurs frequently in native form and some of the finest specimens in the Butte district have come from this property.—The Crystal Copper Co. backed by Boston people, is operating in the Cataract district, 11 miles from Basin. Regular shipments of copper are being made to the Washoe smelter at Anaconda. Walter Harvey Weed is the managing director of the company and associated with him as resident director is Paul Gow, a prominent mining man of this district. The consideration involved was not made public, but it is rumored that it is in the neighborhood of \$250,000. The Goldsmith property was formerly owned by C. W. Ellingwood, a prominent pioneer resident of Butte.—According to a report issuing from the local office of the Tuolumne Copper Co., a big strike was made at the Main Range property. A drift that is being driven easterly on the 700-ft. level of the Spread Delight fissure has cut a zone of high-grade copper ore; a breast 5 ft. wide runs 12.5% copper and 26.75 oz. silver. This ore was found at a distance of approximately 260 ft. east of the main cross-cut on that level. As this drift progresses it gains depth by reason of penetrating a high hill, and a maximum depth of about 1200 ft. will be attained. The Tuolumne has rights on the strike of this fissure for a distance of 1100 ft. beyond the point of the present breast. The driving of a raise from the 700-ft. level of the Main Range mine to the 500-ft. level is proving the continuation of the orebody and a considerable tonnage of ore is being blocked out. A feature of the ore development at this point is the uncovering of native-silver ore which is being found in fairly large quantities.

The erection of an air-compressing and hoisting plant, capable of operating to a depth of more than 2000 ft. and of hoisting 1000 tons per day, is under way at the Sinbad shaft, the principal working shaft of the Main Range property. This is being enlarged to three compartments and will be sunk from the 700-ft. level to the 1100-ft. level.—Sinking is under way at the Colusa-Leonard shaft of the Tuolumne company, which is 600 ft. west of the Sinbad shaft. These two mines are being connected with cross-cuts for ventilation, safety, and economy.

Butte, October 26.

#### NEVADA

##### ESMERALDA COUNTY

(Special Correspondence.)—Ore averaging \$16 per ton in gold and copper has been opened in the alaskite belt by the Jumbo Extension Co. This is the first time ore of a profitable grade has been found below the shale in Goldfield. The vein is a fissure and has been followed through shale from the

overlying latite. It was intersected from a 75-ft. winze sunk from the 1017-ft. level and has an incline of about 30°. A drift will be extended from the 100-ft. level of the winze to explore the vein at that point. J. K. Turner is superintendent.—At a point 200 ft. south-east of the 500-ft. level of the Silver Pick mine, ore assaying \$20 per ton in gold has been found. A strong vein is indicated and the management is centering work at this point.—Ore conditions are improving in the Spearhead and Kewanas mines; a small shipment will be made from the former shortly.—The winze from the 1750-ft. level of the Atlanta has passed the 1900-ft. point and a cross-cut has been started to seek the vein in the alaskite. As soon as the 2000-ft. level is reached another cross-cut will be started. The manager states the best ore yet found in the Atlanta is exposed on the 1750-ft. level, with indications favorable for persistence of the vein into the underlying alaskite.—The Goldfield Consolidated is operating its cyanide plant on oxidized ore from the upper workings and on tailing; it is treating 500 tons per day. The flotation unit is treating copper-gold ore from the deep workings of the Grizzly Bear and Laguna mines, but difficulty in disposing of the flotation concentrate to custom smelters continues to hamper production of this class of material.—It is reported that good ore is being developed in the Surcease mine near Oroville, California, which the Consolidated holds under bond and option.—The new mill of the Silvermines Co. at Hornsilver is ready for service and will start with a capacity of 150 tons per day. At a depth of 510 ft. the shaft entered sulphide ore, and a station is being cut on the 500-ft. level. Water is delivered to the mill through a pipe-line 8½ miles long. S. H. Brady is manager.

Considerable activity is reported from Talicha, the new gold camp near the Nye county line.—Work is being pushed at the Life Preserver, Periscope, and other properties, and high-grade milling-ore is exposed. Recent reports of bonanza discoveries are denied by operators, who state the ore is of good milling character but not particularly rich. At the Life Preserver group, under bond to George Wingfield and associates, four shafts are being sunk on the main vein.

Goldfield, November 3.

#### MINERAL COUNTY

(Special Correspondence.)—An interesting development has taken place at the St. Patrick mine of the Kirchen Mines Co. at Luning which shows the intense action of the copper-bearing solutions that formed the orebodies in that mineral belt. Before starting a stope on high-grade ore, recently cut in the main working level, a cross-cut was run into the foot-wall and this shows the monzonite wall-rock to be heavily impregnated with copper, assaying 2 to 4%.—The first carload of ore to be shipped under the new contract by the Pilot Copper Co. left Luning on October 29. The Pilot company has secured one of the most favorable contracts that the smelters have made in recent years; enabling it to ship 100 tons per day of a much lower grade of ore than had previously been shipped and yet make a good profit.—A rumor is current that a large adjoining acreage, with a fine ore showing, will be added to the Wedge Copper Co. The plan also includes the building of a large reduction plant at the mine.

Luning, November 1.

#### WASHOE COUNTY

(Special Correspondence.)—Though the ore that previously has been mined from the No. 2 vein at the 300-ft. level of the Nixon Nevada has been unusually rich, assaying 20 to 40% copper, with a substantial gold and silver content, there has been a decided improvement during the week and much that is now coming to the surface will assay 75% copper. This brings the first-class ore now in the bin to an average of 50% copper. Two shifts are at work extending the north drift on the No. 1 vein, from which the bulk of the production of the

Nixon Nevada mine up to this time has come. The first ore-shoot found in this drift was 200 ft. long and averaged 28.47% copper and \$19.26 in gold and silver per ton. Two shifts are extending the cross-cut which will tap the No. 4 vein, the biggest of the seven, at a depth of 800 ft. on its dip.

Reno, November 1.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—Friday October 26 a fire started about 8 p.m. in a newly-built oil-burning furnace in the blacksmith shop of the Socorro M. & M. Co.'s plant. This quickly spread to the head-frame and crusher-plant and through the conveyor runway to the upper end of the mill, the upper section of which was destroyed as well as store-houses, machine-shops, assay laboratory, custom ore-bins, and tramway terminal. The fire was controlled, and that section of the mill below and including the Pachuca tanks was saved. This included about \$30,000 in gold and silver. The main shaft burned down but a few sets as the draft was up-cast. All miners escaped without accident through the Little Charlie adit. The loss amounted to between \$200,000 and \$300,000; it was covered by insurance. This month was to have been a record breaker in the tonnage output and the recently favorable development of this property will likely hasten the re-building of the plant. William Childs, the president, and Mr. Cox are expected this week.

Mogollon, October 30.

## OREGON

### JACKSON COUNTY

(Special Correspondence.)—The 1000-bbl. cement factory of the Portland Beaver Cement Co., on the outskirts of Gold Hill, began operations last week with a crew of 85 men. This factory was recently completed at a cost of \$700,000 furnished by local and Portland investors.—The State lime board has taken over the J. H. Beeman limestone deposits lying on the opposite side of Rogue river from the cement factory, and will equip the quarry for furnishing the Oregon farmers with limestone fertilizer at cost in excess of \$20,000 at once. This property is 1½ miles from Gold Hill, and the output will be delivered by aerial tramway to the Southern Pacific railway.—M. G. Womack, L. R. Bigham, and George Thrasher, of Medford, are developing a promising quartz gold deposit three miles south of Jacksonville in the Poormans creek, which is a rich placer district. The vein is in a greestone-porphry contact, and 10 ft. wide.

The Manganese Metal Co., of Tacoma, has purchased the J. H. Tyrell ranch in the Lake Creek district for \$18,000 cash. This ranch contains the most extensive and promising manganese deposits in this new mining district, 20 miles east of Gold Hill. The new owners have taken options on two adjoining ranches. Three carloads of mining machinery are on the way from Tacoma to equip the mines. Charles W. Scott, representing the company, is at Lake Creek, and is hiring men and teams preparatory to moving the machinery from Eagle Point.—W. F. Sears of Gold Hill, who recently purchased the Larsen ranch on Kanes creek three miles south of Gold Hill, is preparing to re-open an old gold-quartz vein on the property, and equip it with a small stamp-mill and pumping plant.

Gold Hill, October 29.

### JOSEPHINE COUNTY

(Special Correspondence.)—The Kerby Queen copper mine in Hanfort gulch five miles north-east of Waldo is to be re-opened at once. The property is owned by D. W. Collard of Kerby and is developed by a 900-ft. adit on the lower level and a 300-ft. on the upper level. There are many thousand tons of 4% copper ore on the dumps. The high-grade ore being shipped averages \$6 per ton gold.—The Collard, Moore & Collard chrome mine, near Kerby, will begin to concentrate ore

next week. The concentrator was erected last spring. Over 2500 tons of chrome ore has been shipped from this mine and there are many thousand tons of high-grade ore in sight.

A two-stamp mill has been erected at the Abbott and Williams gold mine on the Illinois river near Selma. The ore runs \$17 gold.—I. L. Thompson of Seattle has made the second payment on the Osgood placer mine, one mile south of Waldo. Preparations are being made for extensive development work. The bedrock in this mine carries platinum.—The Del Norte Claimholders Association has commenced to grade eight miles of wagon road between Waldo and its copper claims in the Preston Peak district. Supplies have arrived and work is being directed by J. T. Gilmore and A. C. Hoffman.

Grants Pass, November 1.

## UTAH

### TOOELE COUNTY

Another carload of copper ore has been shipped from the Frankie mine by the Woodman Mining Co. The main adit in this mine, which is about 2½ miles south from Gold Hill, on the Western Utah Copper, is in 200 ft. This gives a vertical depth of about 120 ft. The portal is in granite, but the adit has been in low-grade ore for 72 ft. The ore occurs on the contact between the granite and limestone. A fair sample of the entire body shows that it carries 2% copper, \$1.20 gold, and 2 oz. silver. On one wall is a streak of three or four feet of richer ore. This samples up to 15 and 20% copper, \$1.50 to \$2 in gold, and 2 oz. silver. At this point a winze has been started.

### PIUTE COUNTY

Howard S. Chappell, president of the Mineral Products company, has returned to Salt Lake from the East and announces that the Marysville potash plant, which burned to the ground on October 25, will be immediately re-built. Already he has placed orders with Eastern firms for approximately \$150,000 worth of machinery and is now negotiating for an ample supply of lumber which will be placed on the ground at once and work will be started without unnecessary delay.

Mr. Chappell states that after the mysterious fires of last spring it was extremely difficult to secure insurance on the plant, but that they finally succeeded and the recent loss is fully covered.

### SALT LAKE COUNTY

Officials of the Boston Development Co., operating the well-known Maxfield mine in Big Cottonwood canyon, are highly optimistic concerning the future of that property. Their enthusiasm is based on recent developments which have disclosed, at a distance of 1100 ft. in the adit, well-defined streaks of high-grade ore, some of which assays 62% lead, 5 oz. silver, \$22 in copper, and \$6 in gold, while the average of the ore found has an estimated value, it is said, of \$165 per ton in these metals. The fissure on which the miners are now working is said to be highly mineralized and it is thought by those conversant with geological conditions in that section to be leading to the bedding from which thousands of dollars worth of high-grade mineral was taken not many years ago.

A. Boulais, the superintendent, was in from the mine a day or two ago and brought with him a magnificent sample of the ore from which much is expected in the near future. A force of nine men is busily engaged pushing development and if expectations are realized shipments from the Maxfield will be in order at no distant date.

## WASHINGTON

### FERRY COUNTY

Renewal of activities in Republic camp has developed a shortage of help. About 100 men are now employed in the mines and the services of many more could be used. About 50 are employed on the Lone Pine, owned by the Northport Smelting & Refining Co., 18 on the Last Chance of the Lone Pine Con-

solidated Mining Co., 18 on the Knob Hill, 5 on the Quilp dump, and several on the American Flag at Sheridan.

#### SPOKANE COUNTY

A shipment of 5720 lb. of tungsten ore, said to be worth \$6000 and the largest shipment ever made from Spokane, was consigned to New York a few days ago. It was composed of several small lots, assembled from different sources.

#### STEVENS COUNTY

Computations of the quantity of magnesite in the deposits of this county have been made recently by the U. S. Geological Survey. Single deposits are estimated to contain over 1,000,000 tons within 100 ft. from the surface, while the deposits of the county are estimated at over 7,000,000 tons. Four companies are operating in the county, namely the Northwest Magnesite Co., the American Mineral Product Co., the U. S. Magnesite Co., and the Valley Magnesite Co. The combined output of these companies amounts to about 700 tons per day. Only a small part of this is calcined material.

### CANADA

#### BRITISH COLUMBIA

Urgent appeals are being received by the Hon. W. Sloan, Minister of Mines for British Columbia, asking him to intervene in the silver-lead situation created by the decision of the Trail smelter not to handle ores containing more than 4% zinc. Unless immediate relief is obtained, many properties will be obliged to close down. In a telegram to the Provincial Premier, who is now at Ottawa, the Minister says that practically all the silver-lead mines of the Province, with the exception of two or three, will be closed down. He proceeds: "It will probably relieve the situation if the order in council, prohibiting exports of nickel, zinc, and lead, if lifted, so far as the United States is concerned. This matter is most serious and disastrous to our mining industry. Would suggest that you take it up at Ottawa, with a view to getting a definite understanding as to munitions orders and also as to lifting the embargo on exports to the States. The United States should now be in a position to handle our surplus lead and zinc. I cannot too strongly emphasize the alarm of our mine operators; and I am receiving urgent wires from all over the interior, demanding immediate action."

A 'get-together' week will be held by the Vancouver Chamber of Mines from October 29 to November 2. There will be demonstrations and lectures, and the whole affair is being arranged so that it will be of general interest to the public.

Alexander Hardie who died at Sanova recently, is one of the last of the early pioneers of British Columbia. Born in Scotland in 1831 he left for the Californian goldfields in 1854. A few years later he came to the placer-fields of the Fraser river and finally settled in Camerontown in the Cariboo. There he located the Caledonian claim, which has yielded nearly a quarter of a million dollars.

Heavy purchases of mining properties in the Camp McKinney and Fairview districts of British Columbia have been completed by the Consolidated Mining & Smelting Co. of Canada, and preparations are being made for production. About 2000 acres in each camp is involved but the price is withheld. Camp McKinney and Fairview, situated in the neighborhood of Keremeos, B. C., and Molson, Wash., are valuable to the great operations of the Consolidated company because of the silicious-fluxing ores they contain. These will become a large asset in the operation of the smelter of the company at Trail. Included in the acquisitions is the old Cariboo mine in Camp McKinney, famous for its yield of gold. Both camps, about 20 miles apart, are traversed by veins of quartz carrying gold. —Another strike has taken place at Coal Creek, and nearly 900 men are idle. The dispute seems to centre around No. 1 East mine where the men demand an investigation of the yardage on No. 1 level and that an award be made by the Director of Coal Operations.

## PERSONAL

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

W. B. DENNIS is in New York.

F. W. BRADLEY is at Portland.

HOYT S. GALE is at Los Angeles.

J. C. HOPPER is at Silverton, Colorado.

HOBACE V. WINCHELL is now at Butte.

G. M. ESTERLY, of Waldo, Oregon, is in Alaska.

T. J. JONES has returned to London from Russia.

MALCOLM MACLAREN has returned to London from Peru.

COREY C. BRAYTON has returned to San Francisco from Salt Lake City.

H. B. BATEMAN, now Captain in the British Field Artillery, is in East Africa.

E. S. BASTIN is lecturer on geology at the Massachusetts Institute of Technology.

FRANK LAWRENCE has left Shasta county and is now residing in San Francisco.

G. M. CLARK has been elected president of the South African Institution of Engineers.

E. E. HARDACH, who returned from Johannesburg last June, is residing in San Francisco.

W. B. PHELPS is superintendent of mines for the Tom Reed company at Oatman, Arizona.

JOHN RUSSELL is now assistant superintendent for the A. S. & R. Co. at Monclova, Mexico.

W. J. ELMENDORF has returned from a three-months trip in the Copper River district, Alaska.

RODOLPHE L. AGASSIZ, president of the Calumet & Hecla, has returned to Boston from Michigan.

R. B. WATSON, general manager for the Nipissing Mining Co. of Cobalt, is at Phoenix, Arizona.

BYRON M. JOHNSON has been appointed engineer to the A. S. & R. Co.'s mines at Matehuala, Mexico.

T. P. HOLT has returned to Tintic, Utah, from Cobalt, Canada, where he is erecting some roasters.

W. G. ANDERSON has resigned as manager for the Ore Chimney Mining Co. at Northbrook, Ontario.

C. E. STUART, formerly in Mexico, is Captain in the Engineer Officers Reserve Corps at Fort Leavenworth, Kansas.

DONALD G. CAMPBELL, of Campbell, Wells & Elmendorf, is examining mines on Vancouver island, British Columbia.

B. C. AUSTIN has resigned as manager for the Mountain King Mining Co. and will open an office as consulting engineer in San Francisco.

BRUCE MARQUAND, formerly mill-foreman for the Broadwater Mills Co. at Park City, Utah, has taken a similar position with the U. S. S. R. & M. Co., at Silverton, Colorado.

HORACE V. WINCHELL, W. H. WILEY, C. K. LEITH, and OSCAR H. HERSHEY have been testifying, as experts, in the Bunker Hill & Sullivan v. Star-Morning case, at Wallace, Idaho.

H. DEWITT SMITH has resigned as assistant manager at Kennecott for the Kennecott Copper Corporation to accept a position as superintendent of the mining department of the United Verde Copper Co., at Jerome, Arizona.

JUNIUS F. COOK, until recently consulting mechanical engineer to S. Neumann & Co., the Consolidated Mines Selection Co., the Brakpan and Springs mines, passed through San Francisco last week on his return from the Transvaal to New York, where he expects to reside.

The Sulphur Committee of the War Industries Board was in Texas this week. The committee consists of J. PARKE CHANNING, J. W. MALCOLMSON, A. B. W. HODGES, P. S. SMITH of the U. S. G. S., and W. O. HORCHKISS of the University of Wisconsin.

# THE METAL MARKET

## METAL PRICES

San Francisco, November 6

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	16.00
Antimony (wholesale), cents per pound.....	14.75
Electrolytic copper, cents per pound.....	23.50
Pig-lead, cents per pound.....	6.25—7.25
Platinum, soft and hard metal, respectively, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	100
Spelter, cents per pound.....	9.50
Tin, cents per pound.....	62
Zinc-dust, cents per pound.....	20

## ORE PRICES

San Francisco, November 6

Antimony, 45% metal, per unit.....	\$1.10
Chrome, 34 to 40%, free SiO <sub>2</sub> , limit 8%, f.o.b. California, per unit, according to grade.....	\$0.50—0.60
Chrome, 40% and over.....	\$0.60—0.75
Magnetite, crude, per ton.....	\$8.00—10.00
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.	
Tungsten, 60% WO <sub>3</sub> , per unit.....	26.00
Molybdenite, per unit MoS <sub>2</sub> .....	\$40.00—45.00

## EASTERN METAL MARKET

(By wire from New York)

November 6.—Copper is unchanged and nominal at 23.50c. all week. Lead is strong and higher at 5.75 to 6.25c. Zinc prices are quoted at 8 to 6.87c. Platinum remains unchanged at \$105 for soft metal and \$111 for hard.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

The U. S. Geological Survey reports that the secondary tin recovered in the United States in 1916 was equal to about 24% of the tin imported, as

metal or as oxide, into the United States during the year, 69,055 short tons. Secondary tin recoveries increased from 13,650 tons, valued at \$10,554,180, in 1915, to 17,400 tons, valued at \$15,131,040, in 1916.

## COPPER

Anaconda's production for October will amount to about 22,000,000 lb. The zinc plant at Great Falls is now operating practically at capacity and the output will be increased from 20 to 30% by the first of the year through completion of four additional furnaces for roasting of zinc concentrate and high-grade ore. The Washoe smelter is now operating, at three-fourths normal. By request of the Government arsenic production is being pushed and from cleaning of smelter flues at Great Falls 1000 tons will be obtained by December 1.

## ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Date	Average week ending	Sept. 25	Oct. 2	Oct. 9	Oct. 16	Oct. 23	Oct. 30	Nov. 6

Makers of ferro-chrome used in manufacture of high-grade steels and other products have received instructions from War Industries Board that pending a better situation in the chrome-ore supply, henceforth their product must be devoted to Government purposes and be subject to Government control. Automobile manufacturers and munition makers are the largest users of alloy and other high-grade steel, and it may be judged from the ruling issued that the use by automobile companies except on Government work will be made secondary to that by the munition makers. Automobile manufacturers are of the opinion that there will be sufficient supplies of both high-grade steels and ordinary steel to satisfy Government wants and also allow substantial allotments to the making of automobiles. A conference of automobile men and of representatives of the Government board was held on November 2.

The Carnegie Steel Co. has raised the price which it will pay for domestic manganese ore to \$1.20 per unit delivered at its furnaces for ore running 50% and higher in manganese.

## Eastern Metal Market

New York, October 31.

The markets as a whole are in better condition than for some time, since two of the metals are stronger instead of all being dull and weak.

Copper is unchanged and nominal at the Government price.

Tin is more active and considerably higher.

Lead is much stronger and more active, with a recovery in prices after another recession.

Zinc continues inactive and is lower.

Antimony is nominally lower.

Aluminum is inactive and has slightly declined.

In the steel market, prices have been dropping toward levels which are regarded as marking the new maxima. No further price-fixing is now announced, but adjustments on commodities not already fixed will be agreed upon by those interested. The whole movement indicates a broad spirit of confidence in the steel-makers' representatives. Buying of pig-iron is not very active on account of the unwillingness of furnaces to accept additional orders.

### COPPER

So far as official information is concerned the copper market remains unchanged. It is apparently completely in the hands of the Copper Producers' Committee which is stringently regulating deliveries of metal to consumers with a view to conserving supplies for the Government and its Allies. It is impossible to confirm reported sales by large producers at the Government price of 23.50c. per lb., New York, which they continue to quote. It is stated that for first-quarter delivery sales have been made at the 23.50c. price, but subject to any change the Government may then make. The actual business of the committee, according to an authority of weight, is done through the United Metals Selling Co. and the American Smelting & Refining Co., which have become practically the business agents, the former representing the United States government and the latter the foreign countries. On orders received these agents requisition the several producers to fill orders according to information as to their ability to supply the material desired. The two agents render bills to the governments and then remit to the various producers. The position of the small dealers and consumers is still unsolved so far as official information is concerned. Proceeding on the assumption that sales of small lots can be made safely at above the official price, the same as in the case of steel jobbers, copper continues to change hands, but the realized price is reported now to be more nearly approaching the Government level. The London market is unchanged at £125 for spot electrolytic and £121 for futures.

### TIN

The market for spot tin has become more active, due to an acute shortage and to some doubt as to the ability of small buyers to obtain further supplies. The market has advanced 4.37½c. per lb. in the past week, until yesterday spot and nearby tin was quoted at 66c., New York. After a quiet day on Wednesday, October 24, when about 100 tons changed hands, the new activity started on Thursday with the appearance of good inquiry for early delivery but with few sellers. Outside the occasional spot inquiry, however, the market was for the most part quite uninteresting. Buyers of spot, however, became nervous, and this helped other positions so that on Friday, October 26, sales of at least 500 tons of all brands for all positions were made. The fact that the license question is not as easy as was expected has had its influence on the sharp rise in spot. Cablegrams also continue to be delayed daily, and often do not arrive in time to conduct business. On Mon-

day a buyer of 50 tons could only obtain small lots, even bidding up to 65c., New York. The spot situation became still more acute until yesterday, when spot sold in small lots at 66c., New York, with plenty of buyers but a lack of sellers. Arrivals up to and including October 29 were 2060 tons, with the quantity afloat 4300 tons. The London market for spot Straits has advanced over £9 per ton in the week, the quotation yesterday standing at £256 10s.

### LEAD

The continued decline in the lead market reached its culmination last week when, on October 24, the American Smelting & Refining Co. reduced its price again 1c. per lb., bringing its quotation to 5.50c., New York. This was lower than had been expected and the trade was thrown temporarily into consternation. Previous to this, each cut by the leading interest had been met by a cut on the part of the independents. The new price was evidently regarded as rock-bottom and its establishment evidently had the effect intended. Since then inquiry has been large, and consumers, whose stocks were probably very low, have come into the market. By the end of last week, Saturday, prompt and November shipment was selling from 5.50 to 5.60c. in large quantities. So far this week the market has continued to gain in strength and sales are reported as having been large. By yesterday independent and other sellers had withdrawn from the market, with no one left to supply the demand except the leading interest, and with as high as 5.87 to 6c. asked. Yesterday sales were heavy, as high as 5.75c., New York, having been paid, with some reporting 5.87c., New York, as having been obtained. An advance very soon by the American Smelting & Refining Co. is not unlikely.

### ZINC

The market is devoid of interest and is sluggish to a degree. It has gradually fallen during the past week, the decline being measured by about ¼c. per lb. It is due, without doubt, to the weakness in the lead market. Demand is of small proportions. In the absence of any volume of business the quotation, as judged by or based on the few sales reported, is about 7.75c., St. Louis, or 8c., New York, for prime Western. At this price one or two lots of 100 tons each have been sold within the last two days. It is also reported that a few small lots have gone at 7.62c., St. Louis, or 7.87c., New York, but not all sellers are willing to meet this price. It is still a matter of comment that galvanizers and brass-makers still remain largely out of the market, nor is there any apparent desire on the part of consumers to stock up for the winter in spite of the fact that railroad congestion may interfere with later deliveries.

### ANTIMONY

There is no demand, but quotations for Chinese and Japanese grades are nominally lower than last week at 14.25 to 14.50c. per lb., New York, duty paid.

### ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is a little lower, but demand is of small proportions. It is quoted at 37 to 39c. per lb., New York.

### ORES

Tungsten: Quotations are unchanged at \$26 per unit in 60% concentrate for scheelite, with \$23 to \$25 per unit for other ores. One dealer reports an active market with about 60 tons of scheelite sold in the week. The minimum price for ferro-tungsten is \$2.35 per lb. of contained tungsten.

Molybdenum: For high-grade molybdenite \$2.20 per lb. of MoS<sub>2</sub> in 90% concentrate has been paid.

INFORMATION FURNISHED BY MANUFACTURERS

## COMPRESSED-AIR LOCOMOTIVES IN BIG COPPER MINES

By C. B. HODGES

It is generally known that two underground copper mines in Arizona are today mining 16,000 and 9000 tons respectively of copper ore every day. In these two mines compressed-air locomotives are employed for hauling the ore from the chutes to the foot of the shaft. Moreover, these installations have been made within the last four years, and they represent the best judgment of well-informed mining engineers in the year 1913. This, therefore, means the most advanced practice of the hour. Compressed-air locomotives were decided upon at

PORTER COMPRESSED-AIR LOCOMOTIVE IN ARIZONA

these two mines primarily on account of safety. In both cases the ore is mined by the caving system above the haulage level and is drawn through chutes into the cars. In operating such chutes a trolley wire has been found to be a source of danger, annoyance, and delay. It is dangerous because the men may touch it; annoyance and delay arise from the fact that the men must at all times be careful to avoid touching it and because it is knocked down occasionally and must be replaced. The effort to protect it clutters the gang-way.

The appearance of the locomotives used in these mines is shown by the accompanying illustrations. They were built by the H. K. Porter Co., and are of the two-stage type. The name 'two-stage' has been selected by the manufacturers because expansion is performed in two cylinders in series for reasons quite different from those which suggest a similar arrangement in connection with steam-engines where it is called 'compound.' In steam-engines the expansion is performed in two successive cylinders to decrease the temperature-range in any one cylinder, and so to reduce the cylinder-condensation; at the same time the effect of clearness is reduced and the pressures are equalized. In the compressed-air engine, on the contrary, the primary reason is that the air enters the high-pressure cylinder at, or a little below, the atmospheric temperature. Only a limited quantity of work can be done without rendering it too cold for further use, so the air is made to do as much work as it can without getting too cold in one cylinder. It is then re-heated to atmospheric temperature by contact with atmospheric air, and is made to do as much more

work in another cylinder. By this means, the efficiency of the compressed-air locomotive has been increased 50%, because the work that can be done by compressed air depends upon the heat in it that can be converted into work. If the available heat originally in the air is utilized and is then re-placed, the theoretical working-capacity of the air is doubled.

The locomotives in the larger mine weigh 10 tons, and haul trains of 10 to 20 cars of 5-ton capacity, making about 20

LARGEST COMPRESSED-AIR LOCOMOTIVE EVER MADE

round trips per shift. There are 11 locomotives in the Inspiration mine, but only 9 work regularly. An average of 16,000 tons of ore is handled daily, making the average tonnage for each locomotive 1778 tons. Some locomotives haul less than this and others much more. The average haul is about 2500 ft. one way, and, in addition, the locomotives have to do considerable spotting and shifting at both ends of the trip in loading the cars at the tippie. They are supplied with compressed air by two Ingersoll-Rand 4-stage air-compressors, driven by 650-hp. synchronous motors mounted on the shafts

PORTER LOCOMOTIVE AT HOMESTAKE MINES

of the compressors. These compressors are so arranged that when the pressure in the pipe-line supplying the locomotives reaches a pressure of 1100 lb. per sq. in. the compressor stops discharging air into the locomotive-line and begins to discharge into the general mine-system at 90 lb. pressure. Simultaneously, the power needed drops to about half that required for compressing air to 1100 lb. The compressor installation is very liberal in capacity for present requirements. One compressor working about two-thirds of the time is sufficient to supply all the locomotives. The power consumed is about 37/100 of a kw-hr. per ton of ore handled. As an indication of the accuracy with which the performance of such equipment can be forecasted, it is interesting to know that a preliminary estimate, based on mine plans and other data, placed the probable power-consumption at 0.4 kw-hr. per ton. The compressors are situated in the mine power-house at the head of the hoisting shafts. There are no stationary storage-tanks in connection with this installation.

A system of pipe-lines connects the compressors on the sur-

face with convenient charging-stations underground. These pipe-lines, which are from 2 to 6 in. diameter, have sufficient volume to provide the necessary storage of air. The charging-stations consist of a suitable tee or elbow in the pipe-line to which a valve and flexible metallic coupling are connected. With this device, the locomotives are charged in about 45 seconds. The charging is done once on each round trip, so that from 12 to 15 min. out of each 8-hr. shift is consumed in this operation. One machinist and helper inspect the locomotives and make running repairs. The cost of repair-parts has been moderate and break-downs or delays due to the failure of any part of the haulage-system are almost unknown. David B. Scott, engineer for the Miami Copper Co., says in a recent article on the mine-operation: "The power-consumption of electric and compressed-air systems per ton-mile, reduced to kilowatt-hours for compressed-air systems using electric power for compressing air, can generally be rated within the following limits: Electric trolley-systems, 0.8 to 1. kw-hr.; electric storage-battery systems, 1 to 1.8 kw-hr.; compressed-air systems, 0.8 to 1 kw-hr. The power-requirements of the electric and compressed-air systems show little difference in efficiency. The power consideration is, however, second in importance to maintenance, upkeep, and flexibility. Compressed-air locomotives, while more bulky in size than electric motors, have the same range of application as the latter to metal mining; they are used in both the lode deposits and in large disseminated deposits. The common range of sizes now in use is from 4 to 10 tons. Haulage-ways do not necessarily have to be large to accommodate this type. The Homestake mine employed 4½-ton locomotives on an 18-in. track; the Inspiration mine uses 10-ton locomotives on a 30-in. track. Two-stage types of locomotives are used almost exclusively, since they are more economical, and the cost of installation of the plant is less than that for the single-expansion type."

Compressed-air locomotives were adopted at the Inspiration mine after electric locomotives had been used for several years. The conditions to be met were in many respects similar to those in the Homestake. Eight-ton locomotives are used and there are 12 hauling to two shafts. The hauls are from 2500 to 5000 ft., but only 9000 tons of ore is handled per day; 10 locomotives are used and two are spares, so that each locomotive handles about 900 tons of ore, and this is just about half the duty performed by slightly heavier locomotives at the Inspiration mine. This is partly accounted for by the smaller size of the locomotives and by the longer hauls; but the main reason is the character of the ore. At the larger mine, the ore breaks into small pieces, it is dry, and it runs freely through the loading-chutes; whereas at the smaller mine considerable time is lost in getting the ore into the cars because the ore sticks and has to be loosened with bars or powder. This detains the locomotives at the stations where the ore is loaded, and it reduces the quantity hauled per locomotive. The locomotives are supplied with air by two 4-stage Ingersoll-Rand air-compressors. The piston-displacement of each air-compressor is 600 cu. ft. They are driven by 200-hp. motors. The compressors are placed in the mine power-house and the compressed air is conducted into the mine by a system of pipe-lines connecting the compressors with the charging-stations so situated that the locomotives can be supplied with air without unnecessary running or loss of time. These two installations are of more than ordinary interest for these reasons: First, because in both cases electricity is transmitted considerable distances to the mines and is there used to compress air for the operation of locomotives; second, because in one case electric locomotives had been used for a number of years and were discarded; and, third, because the men who did these things seem well satisfied with what they have done.

The WALTER A. ZELNICKER SUPPLY Co. has recently secured the services of W. H. Bramman, who is acting in the capacity

of assistant to the president. Mr. Bramman, before becoming associated with the Zelnicker Supply Co., was connected with the American Carbon & Battery Company.

## GRAPHITE CRUCIBLE PRACTICE

The Merrill Metallurgical Co. of San Francisco has been appointed Pacific Coast representative of the Jonathan Bartley Crucible Co. of Trenton, New Jersey. Two attractive catalogues are issued, which give a large amount of interesting information that will appeal to foundry managers and to those having to melt bullion and cyanide precipitate. Mr. Bartley has developed many new types of graphite crucible as a result of years of experience and testing. Speaking of crucibles for tilting-furnaces he says: "As far as the life of a crucible in a tilting-furnace is concerned, all depends on the handling. With proper care they last longer than in an ordinary furnace, because they are not subjected to injury from tongs. To obtain the best results the points to be observed are, (1) the crucible should be properly placed in the furnace, securing it so as to allow for the difference of expansion between the furnace-walls and the crucible; (2) it is necessary to distribute the flame on its entrance into the furnace so that it does not train on any one part of the crucible, but completely surrounds it; (3) adjust the valves slowly and carefully so that no gas goes into the furnace without being entirely consumed, and that nothing but the flame itself comes in contact with the crucible.

"Improper combustion has done more harm to the crucible-maker, as well as to the furnace-manufacturer, than the other faults combined.

"At first glance a stopper appears to be a very insignificant affair, but the part it plays in the steel-plant makes it one of the most conspicuous adjuncts in the manufacture of open-hearth steel. A poor stopper at the bottom of a 20 or 30-ton ladle is liable to create a loss of hundreds of dollars. The composition of a graphite stopper is different from that of a graphite crucible. With the crucible the effort is made to give it an elastic tensile-strength with strong refractory-power. In the stopper it is necessary to produce a regular surface, extremely hard, to withstand an abrasive action and not pliable. This requires special material and special construction. A stopper improperly formed will invariably break off at the 'nose' horizontally, while with a stopper properly formed this never occurs. Our stoppers are made in machines particularly adapted for this special class of work and every stopper is made absolutely uniform to a degree.

"Crucibles are formed or 'turned up' in plaster of paris or wooden molds, much the same as ordinary pottery ware. At the time of making they contain about 20% moisture. When in the drying process this moisture has been expelled, the crucible has undergone a physical change. In other words, it is 5% smaller than it was at the time it was made. During the period of drying, in order to compensate for the shrinkage and to keep the mass homogeneous, Nature has her own fixed laws. It requires from four to six weeks to dispel this moisture sufficiently to go through the burning process. The object of the crucible-maker's burning is simply to calcine the clay in the mix. The physical properties of the clay are changed—it is clay no longer. Yet, while it has lost its plasticity, it will, on becoming cool, absorb very readily what is known as hygroscopic moisture, or, in other words, the moisture that is in the air. Just how much it will absorb depends entirely on the amount of moisture there is in the place it stands. For example, we have made tests showing that in one instance a crucible was taken from our kiln, tested, and found to contain less than 0.25% moisture, placed in a room where the temperature registered 90° F., and five hours later it contained 2.7% moisture. It was then submitted to an atmos-

pheric condition, and five hours later it contained 4.5% moisture. From this illustration the value of proper annealing can be seen.

"To anneal properly there can be no 'cast-iron' rule. Every shop or foundry has a condition that confronts it, and where in one instance A could use his core-oven consistently to properly anneal his crucibles, it would be ruinous for B to adopt this method. A might have a shop where few cores were used and the oven could be almost entirely devoted to the annealing of crucibles; B might have an oven where cores were used extensively and the cores might be large. To place crucibles in an oven with a load of wet cores would be something like putting a cat in the same cage with a canary bird. The crucibles would quickly absorb the moisture, and while sufficient time and heat would eliminate danger to both, the practice is generally considered dangerous. Another method of annealing which is popular among small foundries is to place a crucible on top of a furnace. This practice in most cases is all right provided the melter uses discretion. Crucibles, as a rule, when they arrive at a foundry contain from 4 to 5% moisture. If they are placed at once on top of a very hot furnace there is a chance of an immediate 'scalp', and should they show no external damage, a too sudden annealing might cause an internal fracture which would in a few runs develop a leak, or what are commonly known as 'pin holes.' The best device for annealing crucibles is a furnace built expressly for the purpose, using the waste-heat from the furnace on its way to the stack. These can be built so that the heat can be regulated and the temperature brought gradually from zero to or above 250° F. The average size of crucible, say No. 60, should remain at this temperature at least 48 hours before going in the furnace. Larger sizes require more time.

"In use there is nothing more detrimental to a graphite crucible than the gases that arise from impure fuel. While their influence is indicated on the interior of the crucible, their deadly effect permeates the entire wall and it frequently happens that while the crucible has leaked or cracked in its early life, the walls retain their original thickness, but, when broken, exhibits a dead dull color, showing that the life has been extracted by the pernicious influence of the gases. Both coal and coke which contain sulphur to any great extent will produce this result, particularly if used in a wet or damp condition. Imperfect combustion with oil or gas will also act similarly, due to the fact that in the coal or coke-fire the crucible is almost completely submerged by the fuel and thus protected from the extreme oxidizing condition, thereby getting the bad effect more at the top of the crucible, whereas in the oil or gas-furnace imperfect combustion affects the entire surface. These gases are always produced at low temperatures, usually in a coal or coke-fire immediately after a fresh charge of fuel, and in the oil or gas-furnace by a slight manipulation of the air or fuel valves. It is noticeable that the crucible used in melting steel is never affected by these gases, and this is explained by the fact that they are plunged into a heat sufficiently high to cause good combustion of the gases, and, while this terrific heat, together with the fluxing action of the metal at this temperature tends to make the life of the crucible short, it will be noticed that the wall, however thin, retains its original appearance and nature. Great care should therefore be given to the fuel, seeing: first, that it is as pure as possible; second, that it is perfectly dry; and, third, that it is charged properly at the right time.

"Before using, the crucible should be slowly brought to a heat of 250° F., or over, but if this is accomplished too quickly a 'scalp' is the result, or an internal fracture which will afterward cause a leak. A No. 200 crucible requires about 10 hours to bring up to this heat. The pot should then be immediately filled with metal, and a heat taken off without allowing it to cool and charged back hot if possible. On crucibles above size No. 50, tongs with double prongs should always be used,

and preferably of the 'grab' pattern. The upper prong prevents the pot from wobbling, and the 'grab' device prevents squeezing. The tongs should grip the crucible below the bilge and lift it without undue pressure, as if it were in a shank or a basket. When a crucible is at white-heat it is soft and leathery, and many crucibles are ruined by forcing the tongs together and pounding a ring on the handles. It is a great advantage to have two sets of tongs for every crucible; one for the new pot and one for the pot half used, which is smaller. The tongs should be 'shaped up' at frequent intervals. The melter must not expect as many heats in melting one metal as another. From three heats in melting nickel, to five or six in melting steel; approximately twenty-five are reached in melting copper, while the heats run into the forties in melting composition. If the crucible can be re-charged and put back into the fire at once, a greater number of heats will result than if it is set away and allowed to cool between each heat. The time of heat is also to be allowed for. If the heat is taken off in an hour or so, the crucible will not last as long as with the lighter punishment of a 2 to 2½-hour heat. Don't leave any metal to cool in the crucible, but pour until the melting pot is entirely empty. Buttons may have small threads of metal which will attach themselves to and tear the walls of the pot as they come out; if left in the crucible, when the next heat is taken off, they expand more rapidly than the walls and break the pot. Do not allow ingots to wedge in charging a crucible, but place them in loosely, or expansion will break the pot. See that the crucible has a good bottom to rest on in the furnace. Bricks should be smooth and level—not on edge or set corner-wise. A hard piece of clinker will punch a hole through the bottom. It is an easy matter to punch a hole through a hot crucible with a poker. Always place the pot in the centre of the furnace, so that there is an equal fuel-distribution all around, and turn the pot partly round after each heat. This insures equal wear on all sides. Shanks of the scissors-pattern are hard on crucibles, because of the tendency to seize the pot too high up and squeeze it. The plain ring-pattern shank is the best. The ring should be wide and tapered to conform to the contour of the crucible. It is not necessary to use clips with this style of shank. The fuel should be dry. Wet fuel produces moist gases and steam, which causes 'alligator cracks.' Sulphur in the fuel shortens the life of the crucible materially; 25% more heats have been obtained by a change of fuel. At the beginning of the heats, the top of the crucible should be 4 to 6 in. below the bottom of the flue-hole, and if the work will permit, the space around the pot and at the bottom should be sufficient to hold enough fuel to take off the heat without re-coking. A deep narrow furnace is preferable to a shallow wide one. The drafts and dampers, if arranged to produce a reducing atmosphere, will lengthen the life of the melting-pot. An oxidizing flame is always unfriendly to a plumbago crucible. The clinkers should be removed from the sides of the pot as the tongs are put on, and from the bottom of the pot before it is set on the floor. It should always be set on a bed of dry sand; never on hard bricks. In melting scrap and dirty metal, the inside of the pot becomes thickly coated with slag, and this should be removed with a scraper. It can easily be accomplished when the pot is hot. Then the crucible has more holding-capacity, and the heat passes through it more readily. It is bad practice to leave the metal on the fire after it is ready to pour; soaking in this way an extra half hour has a more injurious effect on the crucible than the entire previous heat."

The CARNEGIE STEEL Co. has just issued a new edition of its well-known 'Shape Book.' The company says, with justice, that the progress of the steel industry is recorded by the successive editions of this steel-builder's handbook. The demands of an age in which rapid change has taken place in building stronger yet lighter and simpler structures, are indeed re-

flected in these pages. The swiftness of the changes required in steel-shapes to meet the new demand is shown by the fact that this 6th edition supersedes the 5th that was issued but two years ago. Forty-eight pages have been added in order to present the increases in the number of sections now rolled. These pertain notably to shipbuilding bulb-angles, but also to many recent forms of sash and casement sections, automobile sections, and cross-ties. These items are sufficient to reflect, first of all the great impulse that marine architecture has received in this country, urged on because of the need of saving France and England from destruction, and then the swiftly accelerating tendency to protect property from the useless waste of fire, which has called for window and door-frames and sash to an unprecedented extent. The time is approaching when the construction of more combustible buildings will seem as monstrous as the easy relations a past generation maintained with feebly-quarantined pestilence. Thus will advancing standards of living call for more steel than has ever been produced. Every engineer is aware of the useful tables assembled in this book, which afford data needed in designing, and which give to the volume the importance of a *vade mecum*. It is beautifully printed, is bound in flexible green leather, and is further embellished by gilt edges. It is for sale at the offices of the company. The price is \$1 postpaid.

## USE OF LOW-GRADE POWDERED COAL

The following conclusions regarding the efficient utilization of low-grade fuels by F. Parkman Coffin, the chief of the General Electric Co.'s research laboratory, are of interest at this time of fuel-scarcity.

"Low-grade fuel may be burned on grates in furnaces of special construction for each class of fuel, and mechanical stokers are available for burning high-ash coal and lignite. It is probable, however, that low-grade solid mineral fuels of all kinds can be burned to better advantage in pulverized form. Lump-coal, when burned on a grate in a hand-fired furnace, usually requires about 100% excess air. With modern mechanical stokers the usual practice is to use about 50% excess air. With most kinds of pulverized fuel 25 or 30% excess air is sufficient, and with proper attention the amount may be reduced almost to zero. However, the resulting temperature of the fire is a limiting factor. Other factors having a bearing on this are the construction of the furnace, the proportion of heat radiated directly on the tubes, and the fusibility of the ash. A properly constructed furnace and burners should be able to burn any form of pulverized fuel which has sufficient volatile content. For the firing of steam locomotives, pulverized fuel offers a method of mechanical stoking that is beyond competition in all parts of the country where oil is not already in use. It also furnishes a means of utilizing neglected fuel.

"Coal can be pulverized more cheaply than it can be gasified, and the first cost of a plant for drying and pulverizing is less than for a producer-gas plant. When thoroughly mixed with a blast of air in correct proportion it is practically a gaseous fuel. Powdered-coal firing has most of the advantages of gas or oil-firing for steam-boilers, when properly applied, and in industrial heating its field of application is constantly growing. There is little doubt that the most perfect combustion of highly gaseous coals, like lignites, could be brought about by burning the pulverized material in a properly constructed combustion-chamber in a draft of air. Such a method, to a limited degree, has been employed with bituminous waste for years in several industries in which large ovens are used, but the machinery and appliances required have hitherto been too large and costly to permit of their general adoption in small heating or boiler-plants. There seems to be no good reason why some satisfactory method of using lignite in this manner in small plants cannot eventu-

ally be evolved. Pulverization of highly gaseous lignites produces fuel with properties closely similar to those of crude petroleum or crude gas; in fact, pulverized high-gas coal like dry lignite, when fed into a furnace with an air-blast, gives largely a gaseous fuel. With the temperature of the furnace or the combustion-chamber once at the proper point, by means of valves the relative supply of coal and air can be regulated so quickly and so perfectly that nearly complete combustion of the heat-producing constituents can be obtained. Besides, with the proper equipment, the feed and the fire should be closely uniform, almost automatic, and requiring comparatively little work from the fireman. When dry pulverized lignite can be used in small boiler settings to advantage there is no reason why it should not produce a relatively high heating efficiency, for, in a proper combustion-chamber, besides the combustion of fixed carbon, this method would utilize nearly all of the volatile gases, which have high calorific power, a proportion of which is lost by the ordinary methods of combustion. The efficient utilization of our fuel-supplies is a subject of constantly increasing importance. Interest in this subject in America has usually been confined to the advocates of the conservation of natural resources. The fuel-supply is still abundant, and it has usually been cheaper to burn high-grade coal or fuel-oil than to bother with peat, lignite, or some of the poorer grades of coal containing a high percentage of ash. In some mining districts a portion of the coal is regarded as refuse for filling, or is thrown on the culm-piles. The reserves of bituminous coal and lignite in the United States are immense, but the supply of some of the higher grades, such as coking-coal and anthracite, may be exhausted during this century. The unrestricted use of the better-grade fuels, and the ruthless waste and neglect of fuels that should be of real commercial value, are phases of national extravagance that are little short of appalling. The Bureau of Mines has repeatedly called attention to the rate at which the supplies of high-grade fuel are being depleted, and the need of investigation to ascertain how waste in mining and utilization can be lessened or prevented. In spite of the immense resources, we are now face to face with a serious coal-shortage owing to limitations of transportation and of labor at the mines. At the same time there is an unprecedented demand for coal.

"Parts of the country distant from supplies of high-grade fuel should endeavor to utilize their local resources to a greater extent than heretofore, in order to eliminate the expenses and uncertainties of transportation. Also the development of low-grade fuel-deposits should be stimulated and established on a permanent basis. The production of high-grade coal and petroleum is fairly well localized, but nearly every part of our continent has local fuel-resources within moderate distances of points of consumption. Low-grade fuels are those which have a low calorific value due to the presence of impurities such as ash and moisture. Fine screenings and dust produced in preparing certain high-grade fuels for the market may also be included, since it is often difficult to burn them on the grate, when using forced draught, even when mixed with lump-coal."

THE UNITED STATES CIVIL SERVICE COMMISSION announces an open competitive examination for assistant coal mining engineer, for men only. Two vacancies in the Bureau of Mines, Department of the Interior, for service in the field, and future vacancies requiring similar qualifications, at entrance salaries ranging from \$1800 to \$2400 per year, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. Certification to fill the higher-salaried positions will be made from those attaining the highest average percentages in the examination. Applications must be filed with the Commission at Washington prior to the hour of closing business on November 13, 1917.

LABOR AND THE I. W. W. ....	706

Common attitude of employers and employees; the contract principle permits willing workers to earn more money; it develops team-work; the spirit of soldiers who have fought for their country will oppose the anti-social purposes of the I. W. W. and promote equal opportunity. *M. & S. P., November 17, 1917.*

THE RUSSIAN CRISIS.....	706
-------------------------	-----

Opposing views on the Russian situation; Lenine represents the spirit of the I. W. W. and of Germany; failure of the moderate liberals; contrast between the Russian and the French revolutions; Russian crisis a result of ignorance supplemented by German intrigue. *M. & S. P., November 17, 1917.*

FOOD FOR THE WAR.....	707
-----------------------	-----

Growing interest in food-thrift; need of using local supplies; shortage of grains for use at home and for feeding our Allies. *M. & S. P., November 17, 1917.*

THE PHOSPHATE OUTLOOK.....	708
----------------------------	-----

The scarcity of fertilizers; our immense supply of raw phosphates; difficulty in providing sulphuric acid for conversion of soluble acid phosphate; new process for extracting phosphoric acid. *M. & S. P., November 17, 1917.*

### DISCUSSION

RUSSIA IN WAR TIME	
--------------------	--

By L. A. MEKLER..... 709  
Misinformation regarding Russia always disseminated through news agencies; the cost of living not exorbitant outside of leading centres; labor situation bad; prompt assistance by United States will help Russia to a stable government. *M. & S. P., November 17, 1917.*

FREIGHT-RATES ON DRILL-STEEL	
------------------------------	--

By H. D. STALEY..... 710  
Improper and ambiguous classification of drill-steel leads to discrimination between shippers of mixed carloads and straight drill-steel; re-classification urgently needed. *M. & S. P., November 17, 1917.*

TUNGSTEN	
----------	--

By CHARLES HARDY..... 712  
Specifications of different buyers of tungsten ores; method of treatment determines different market demands. *M. & S. P., November 17, 1917.*

A PLEA FOR LABOR	
------------------	--

By J. F. HARRINGTON..... 713  
Careless criticism of labor conditions by correspondents; value of contract-system. Americanism in labor. *M. & S. P., November 17, 1917.*

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.

Entered at the San Francisco post-office as second-class matter, Cable address: Pertusola.

Branch Offices.—Chicago, 600 Fisher Bdg.; New York, 3514 Woolworth Bdg.; London, 724 Salisbury House, E.C.

Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries in postal union, \$5s. or \$6.

Transporting Union Drill over 40-Mile Trail

These field Photographs show what can  
be done with a

## UNION CHURN DRILL

Upper picture shows the drill being transported over forty-mile Alaskan trail.

Center picture—drill set up and drilling  $6\frac{3}{4}$ -in. diam. hole to a depth of 60 ft. at rate of 2 to  $2\frac{1}{2}$  ft. per hour using  $\frac{8}{10}$  gals. gasoline per hour.

Base picture shows drill being moved to next hole by drill-crew. Weight on wheels 2150 lbs.

Insert shows a block of granite, fifteen inches thick, with a  $4\frac{1}{2}$ -in. diameter hole drilled through in a demonstration. Time, one hour and fifteen minutes.

Pacific Coast, in British Columbia and Alaska

**L**EACHING of copper ores continues to engage the attention of progressive metallurgists. Elsewhere in this issue is printed a suggestive article on this subject by Mr. A. E. Drucker. Descriptions of the leaching practice at Bisbee and Ajo will appear in proximate issues of this paper.

**W**E regret to record the death, at the early age of 50, of Dr. E. F. Roeber, editor of 'Metallurgical and Chemical Engineering,' New York. Born in Germany, he came to this country when 27 and soon made himself a leader in electro-chemical research. An industrious, capable, and kindly man, he won an honorable position in technical journalism and also the personal regard of a wide circle of friends.

**O**NE of our local organs of misinformation undertook to define for its readers the various Russian factions. The Maximalists, we were told, constituted a party that insisted on "the maximum programme of extreme Socialism." That seemed the limit of radicalism, but apparently it was not, for we were informed immediately that the Bolsheviki were "Maximalists raised to the n-th degree." The plain truth is that 'Bolsheviki' is the Russian equivalent for 'Maximalists,' which is a curtailment of Maximumalist, the meaning of which is obvious.

**S**TATISTICS issued by the U. S. Geological Survey indicate a decided decline in the domestic production of spelter, the output having decreased from 180,569 tons in the first quarter to 132,700 tons in the third quarter of the current year. Stocks are increasing. The number of idle retorts on September 30 represented 28% of the total, and included 18 entire plants. It is evident that an unprofitable production has been maintained by several smelters during recent months in order to retain their labor force in the expectation of obtaining Government orders, which have not come on the scale expected, so that a curtailment of operations has been forced.

**W**E publish two short articles on manganese. One we owe to the Geological Survey and the other to the Bureau of Mines. They supplement each other. Both are timely. Philipsburg, formerly associated with the highly profitable mining of silver, as represented by the famous Granite Mountain mine, is proving an important

source of manganese. So also is the Lake Superior region, heretofore associated with copper and iron. If steel-makers can modify current practice so as to utilize ferro-alloys containing moderate proportions of manganese the pressure to secure high-grade manganiferous ore will be relieved. Converter-slugs relatively rich in manganese are now being utilized to some extent by being charged into the blast-furnace, and the Mayari ores of Cuba, which have a considerable manganese content, are also employed with success. The question would seem to involve chiefly an improvement in technical methods to meet a condition that did not exist while sources of high-grade manganese ore were open.

**U**TILIZATION of liquid oxygen to form an explosive in connection with carbonaceous material has been revived by Mr. George S. Rice of the Bureau of Mines. It is proposed to erect an experimental plant under Government auspices, in co-operation with the producers of the liquefied gas, who have shown great interest in the project. In a recent discussion before a meeting of the Mining and Metallurgical Society of America, Mr. Rice stated that shortage of materials commonly used in making explosives had led the Germans to adopt liquid air for saturating cartridges of carbonaceous matter to be employed for blasting coal in the mines of Upper Silesia. It was claimed that the efficiency of this makeshift explosive was equivalent to dynamite at 12 cents per pound. Mr. Rice is using a mixture of various carbonaceous substances placed in a cheese-cloth container along with a detonator; the cartridge is then dipped into liquid oxygen, and although the best grade of oxygen at present obtainable is composed of only 55% of that element, a strength equal to about three-fourths that of 40% dynamite is realized. The function of the oxygen, of course, is to completely and instantaneously oxidize the carbon, the suddenness of the effect being such as to bring it within the realm of detonation. A large amount of information regarding explosives made with liquid oxygen is available, as this subject was extensively investigated about 18 years ago by a distinguished chemist, Sir James Dewar, in England. An experimental plant for its manufacture was also under consideration, if not actually erected, at Boston by a subsidiary of the British corporation. The investigations then made indicated

favorable possibilities for the oxygen explosive, though some difficulties were experienced. Financial troubles prevented Dewar from continuing his efforts to commercialize the invention.

THE University of California is served by a publicity agent that is remarkable for an exuberance detrimental to accuracy. Twice a statement has been given to the local press asserting that the Research Council of the State Council of Defense had discovered a way of making cyanide so cheaply as to be of immediate assistance to the citrus industry of California and also to the gold mines. We asked Professor John C. Merriam, the chairman of the Council, and he informed us that the statement was not warranted, but that a great deal of useful work was being done, some of it of a promising kind. Such undisciplined publicity is injurious to the University and stultifying to those concerned. On the other hand, it is true that the Bucher catalytic process for the production of cyanide has opened the way for successfully manufacturing it with relatively inexpensive equipment. We published, in our issue of October 13, the details of an ingenious adaptation of Bucher's idea by Mr. G. H. Clevenger, in which he used a few pieces of gas-pipe, an assay-furnace type of gasoline-burner, and a few other odds and ends, with which he made sodium cyanide in sufficient quantity to perform laboratory leaching-tests on gold and silver ores. These experiments were suggestive of a method by which cyanide could be produced in small plants under the direction of clever chemists and mechanics.

## Labor and I. W. W.

Under 'Discussion' we publish a genuine, and therefore interesting, plea in behalf of labor. It is true that most laborers think only of getting more money for their work and that most employers think only of getting more work for their money; that is why there is so much friction. Neither attitude is honest, in so far as each tries to get more than he gives. We agree with the writer of the letter, Mr. J. F. Harrington, that goodwill and fair dealing furnish a basis on which employer and employee can co-operate to better advantage; but he has ignored the chief advantage of the contract system as adopted in mines. It is not to substitute the contractor as a driver instead of the foreman as a supervisor; the idea is that if the men are paid for extra work, they will do it; the contractor is one of themselves, merely the partner in whose name the contract is made. In the mines with which the present writer was professionally connected the system of contracting was a means of developing team-work among a small party, usually four, six, or eight, joined in an effort to drive a level or sink a shaft at an agreed price and with such speed as would yield them considerably more than day's pay. Of course, the best way to get a square deal is to give one, and the quickest way to get euchred is to try to trick the other

fellow. As to the I. W. W., we cannot discuss them patiently during this time of War, nor with any pleasure at any time. The I. W. W. is the problem of the hobo; it is anti-social, subversive of all government, including "government of the people, by the people, for the people," an ideal that we shall not willingly let die. We have no fear lest the brave men that come home from the trenches will subvert existing institutions in favor of the sentimental savagery of the I. W. W. "Liberty and justice" are implicit in the American idea, certainly, but we do not connote them with Haywood and St. John or any of the other irresponsible conspirators that have prostituted unionism in their own interest and that of a small group of anarchists. We believe in collective bargaining, in unionism; we believe that the laborers should combine lawfully to protect their interest, just as the capitalists combine in corporations and syndicates to conduct their business advantageously; but the chief cause of labor unrest is the fact that so many of the most intelligent men do not join the unions, whereas too often they are dominated by ignorant hot-heads or by rank outsiders, who employ the unions to blackmail the companies. If that element, usually non-resident, the Butinskis of industrial unrest, as bad as the Bolsheviks, could be excluded and the unions composed of all the employees organized in self-protection, and not for an economic hold-up, there would be fewer strikes, better feeling, and a larger prospect of developing true Americanism, which means an equality of opportunity under the law.

## The Russian Crisis

Conditions in Russia are engaging the attention of most of us. We are glad therefore to publish a letter from a Russian engineer, Mr. L. A. Mekler, criticizing the recent article by Mr. Horace V. Winchell, whose contribution, in our issue of October 27, was particularly timely and interesting. It must be confessed that the logic of events appears to be against Mr. Mekler and on the side of Mr. Winchell; the optimism of the one has been stultified by recent happenings, whereas the pessimism of the other has been sadly justified. For the moment Nicholas Lenine and his international group of I. W. Ws are in control, proving the culmination of German penetration and propaganda. The Russian people are cutting a sorry figure and it is unlikely that they will come to their senses until they realize that they must either hang together or be hung separately. The unfortunate feature of the Russian revolution is that it went much further than was intended by those originally responsible for it. The moderate Liberals, men like Lvoff, Milyukoff, and Rodzianko, aimed at constitutional reform and had no expectation that all constituted authority would be swept suddenly into the discard of political chaos; they hoped to open the doors for democratic government, but when they pushed what seemed to be such a door of progress they fell headlong into the

dark void of undisciplined revolt; instead of preparing the way for a democratic change of government they found themselves in the midst of a mob of talkative visionaries and traitorous anarchists. The Russian public has been fed on false analogies with the French revolution. That historic uprising happened among the best educated people in Europe; the Russian revolt destroyed the government of a people that, taken as a whole, is the least educated in Europe. About 80% consists of ignorant peasants. France had a population of only 30 millions in 1789, and the revolution was accomplished in Paris, which then had only 600,000 inhabitants. At that time, the swiftest communication was effected on horseback; last March in Russia the post and telegraph brought 180 millions within the range of the great event. Again, whereas Paris was the heart of France, Petrograd is only the stomach of Russia; it is a cosmopolitan city, poisoned by German intrigue, and out of sympathy with the rest of the country. As soon as the revolution occurred, the Russian soldiers at the front were told that the land was about to be distributed to the people and that they had better hurry home to get their share. They deserted by the thousand, they seized trains and scurried homeward. The story of a division of the land was one of the many lies spread by German agents, such as Lenine and Trotzky. No such allotment of land characterized the French revolution, nor did the French armies win battles so long as the death penalty for desertion was held in abeyance; it was not until 1793, when discipline was restored by making death the punishment for desertion, that the military power of France asserted itself victoriously. In short, the Russian crisis is a sad exhibition of plain ignorance supplemented by German intrigue, made effective by an international group of anarchists masquerading as socialists. They are not that, they are anti-social. Most of the leaders of the Maximalists have assumed Russian names, but they are not natives of Russia any more than our I. W. W. element is American; it is not even a distinctly foreign element; it is a non-national group of irresponsibly destructive vagrants to whom representative government and liberal ideas are just as alien as a military despotism or a predatory bureaucracy. We may pause to note the curious fact that the Prussian who hates a socialist at home, and suppresses him as much as he can, is quite willing to support the same kind of irreconcilable in Russia; so also while claiming to be model Christians at home they aid the Turk in killing Christians in Armenia. 'To hell with principles' is the expression of Prussian policy. Thus today the world sees the strange spectacle of the Prussian, who has developed social organization to a repulsive tyranny, co-operating with Maximalists, to whom the disorganization of a political catch-as-catch-can is a desirable consummation. Those that aim to spiritualize the human relationship and to develop the ideals of representative government can join heartily in fighting the combined cohorts of the I. W. W. and of Potsdam.

## Food for the War

California has taken the lead in signing pledges to economize food. This is as it should be, for many of the officials of the Food Administration come from this State, and the chief of it is a man of whom California may well be proud. We have printed pledges on advertising pages of several former issues and we do so again on page 8 of the advertising annex of this issue. It has been a pleasure to forward a large number of signed pledges to Mr. Hoover, who, we are authorized to say, appreciates keenly this evidence of support from the members of his own profession. Interest in food-thrift is growing, but it is not nearly as keen as it ought to be. In the course of a recent transcontinental journey to St. Louis the present writer noticed that the ideas of the Food Administration had not as yet made much impression on the dining-car service of the Pullman company. It ought to be possible for the Controller to compel the Pullman company to set a better example. Only in one dining-car, between Kansas City and St. Louis, did we note a sincere effort to follow the suggestions emanating from Washington. In some instances hooverizing was being used by the Pullman people as an excuse for raising prices, serving half-portions at full rates, for example. The idea of using perishable and local products, so as to consume the minimum of those that can be shipped to a distance or of those that have undergone long transportation, was not in evidence. For example, trout, easily procurable in Colorado and Utah, was served for 75 cents, whereas white-fish from the Great Lakes or salmon from the Pacific Coast cost only 50 cents. The prices should be reversed. A prodigal display of white bread is still common; more bread than is wanted is served, to be fingered or broken, and then thrown into the garbage-can. The people of the United States waste more than enough food to feed the whole population of Belgium. To waste food today is a crime—a mean and disgraceful act, arguing no sympathy with the millions now famishing in the countries devastated by war. We discussed the subject on the train with one or two young men and found a not infrequent irresponsiveness, a careless disregard of the fateful crisis. One young man, for example, asserted his right to eat as much meat as he liked three times a day, because, said he, there was plenty of meat, and other food, in the country. Such cases of callous—and callow—detachment from current history may be rare—we would like to think so—but there are many people that refuse to see the necessity for the United States feeding the peoples across the Atlantic. We have tried to explain to our young friends—and some of the older ones—that the United States is fighting not only to keep the world safe for democracy and to assist the victims of autocratic piracy, but to preserve inviolate our own hearths and homes, to prevent our land from coming under the heel of a ruthless conqueror, to maintain the right to live and let live as against the 'verboden' and the 'goose-step' of

Prussian militarism, with its associated 'frightfulness,' and above everything to prevent the destruction of that spiritualizing of the human relationship that is the essence of our kind of civilization. Some of our young men are willing to die for this cause—some have died already—thousands are preparing to face the supreme sacrifices of virile manhood; many of our older men, and women also, are giving all their time and much of their money to the service of the flag and for the furtherance of the national purpose; therefore the least that the rest of us—the run of mine—should do is to save food, for the feeding of our own soldiers, for the sustenance of the gallant men that have been fighting during three long years for what is now our cause, for the nourishment of the peoples that cannot cultivate the soil productively either on account of the numbers of their men in the armies or because the battalions of death have despoiled, devastated, and destroyed their fields and gardens. Every man, woman, and child can help in this work—which is vital. It is no mere bit of sentimentalism; it is no fad of Mr. Hoover; it is no red-tape of the Government; it is an integral part of our warfare against organized hell. The man or woman lacking the qualities immediately useful in war—youth, strength, brains, or money—can help to save food and so assist those more capable than themselves. It is the least that we can do, and the least that we can do should be our very best to help and promote the national purpose—the purpose of the world's welfare, as we understand it. One practical suggestion we give: let every one of us cease to eat 'hot cakes' made of wheat flour. It is one of the most extravagant ways of consuming wheat. To most people the 'hot cakes' at the close of breakfast are an extra, merely the gastronomic tamping of a full charge. Most of us will be better without them and if all agree to abstain from eating them we shall effect a great and useful economy—and not only in wheat flour, but in butter also. If you must fill the chinks, use cakes made of corn or rice, or bran muffins instead. This will seem trivial to some of our readers. It is not. The sinfulness of squandering wheat flour can be made clear by a few statistics. Our Allies will produce 393,770,000 bushels of wheat this year; their normal consumption is 974,485,000 bushels; the shortage is about 580,000,000 bushels, besides a shortage of 673,000,000 bushels of other cereals. The United States will have a crop of 668,000,000 bushels of wheat, as against a normal consumption of 590,304,000, leaving a surplus of only about 80,000,000 bushels, while we shall have a surplus of about 1,000,000,000 of all other cereals. Obviously we must save wheat, substituting other cereals in our dietary. It is a fact determined by physiologists and confirmed by experience in Belgium that wheat bread is indeed 'the staff of life,' the fundamental food of man. If any reader desire to become better informed let him read Mr. Vernon Kellogg's article on 'Patriotism and Food' in the November issue of the 'Atlantic Monthly.' As he says, this association of patriotism and food is not sordid: "It can

be as fine as the spirit of democracy and as ennobling as the struggle for democracy. If we cannot organize our effort in this world-crisis by the individual initiative, spirit, and consent of the people, then democracy is a faith on which we cannot stand." It is as certain as the coming of tomorrow's dawn that if we do not make good in this war we shall be shamed to all eternity.

## The Phosphate Outlook

No apology is due for devoting space to fertilizers, for, apart from the fact that a large proportion of the raw material is obtained by mining or quarrying, and belongs to the mineral industry, we are at war, and it is essential that we and our Allies should be fed. We have devoted considerable space to occasional reviews of the nitrate, sulphur, and potash problems. A glance at the phosphate outlook, then, will complete the review of the important commercial fertilizers. Unlike nitrates, sulphur, and potash, the supply of phosphates is ample, not only for present needs but for many decades, and probably for centuries. The United States is the world's greatest producer of phosphate rock. Florida leads with an annual contribution of two and a quarter million tons or 75% of the total domestic output. Deposits exist in Tennessee, South Carolina, Kentucky, and Arkansas, while an immense belt, discovered in 1906 and since mapped by the U. S. Geological Survey, extends from Salt Lake City to Helena. A survey of these deposits of phosphate rock has disclosed a tonnage greater than any yet discovered in the world. Unfortunately, however, there is a pucker in the persimmon. Phosphate rock is insoluble, and the vegetal kingdom requires its nutriment in liquid form. Previously phosphate rock has been treated with sulphuric acid to convert the insoluble basic phosphate of lime into a soluble acid phosphate, readily assimilable by plant life. Owing to a shortage of bottoms in which to convey pyrite from Spain, temporary embarrassment in the production of sulphuric acid resulted, and at the same time the call from munition-plants reduced the amount of acid available for making fertilizer. Attention has been called to pyrite and pyrrhotite deposits in the eastern States, which were unable to compete with Spain in pre-war times, and we understand that more energetic development of these has been undertaken. Also the western States are beginning to develop larger resources of these minerals. The sulphur deposits of Louisiana and Texas are producing all that can be transported. Meanwhile it has been found that when phosphate rock is fused in an electric furnace with silica and a small quantity of charcoal, coke, or coal, the phosphoric acid is eliminated by volatilization in a very pure state, and can be collected in fume-chambers, leaving a silicate of lime that can be cast into bricks for paving-blocks. The process would seem to be costly, even if the blocks could compete successfully with concrete as a paving material, but with cheap hydro-electric power it may be feasible.

# DISCUSSION

## Russia in War Time

The Editor:

Sir—In the last issue of your journal, there appeared an article by Mr. H. V. Winchell, on 'Russia in War Time,' in which the author after extensive statistical data and comments on the present political, economical, and other conditions, gives his views on the possibilities for American enterprise and capital in that country.

Before commenting on the article, I would like to say a few things with regard to this kind of article in general, and articles about Russia, in particular. Russia has never had a square deal in the United States, because most of the information concerning Russia is given out through the Sunday supplements of the so-called 'popular' press, in cheap novels of no less popular character, and by travelers who, passing through the country in an express train, without knowledge of the language and people, in most cases, would, on their return home, write a book, with such titles as 'Russia from Within,' or 'The Spirit of Russia.' Not only titled or semi-titled travelers succumbed to this folly, but men of sound judgment and great powers of observation, being struck by the peculiarities of the people and the country, could not withstand the temptation to describe and 'explain' what impressed them most.

Destructive criticism is easier than constructive comment, and it is only human nature to make sweeping generalizations. In the result, the picture is anything but what it ought to be, and should have been, if a more thorough investigation had been made, and the first impression not given too much weight.

Knut Hamsun, the great Scandinavian writer, a great judge of human nature, was one victim of this psychological condition, and Mr. Winchell appears to be another, Mr. Winchell having the disadvantage of describing Russia in a period hardly understood even by natives of the country. Many a Russian would not have done better under the conditions confronting Mr. Winchell. He could not help but see some of the things he saw. But facts and figures will say whatever one requires of them. It is the inner meaning and not the outer expression of things that is the more important. Being a native Russian and having the good fortune of having both a Russian and an American college education, I am enabled to appreciate both points of view, and would, therefore, like to explain some of the facts stated in Mr. Winchell's article.

In coming to Russia, an American usually lands in Vladivostok, the only Russian port open to both the

military and non-military freight and passenger traffic. No wonder he meets congestion, disorder, and general turmoil. He proceeds on the trans-Siberian railway, the only artery feeding the front and the rear, and usually congested, even in peace time. If there was a congestion on some of the railroads in this country where, according to Mr. Winchell's own statistics, there are three times as much railroad tracks per mile, and where there are many routes from one point to another, is it anything but natural that the service on this Russian trans-continental railroad is not what one would expect under normal conditions?

At the end of the journey, the traveler, already brought to the highest pitch of nervousness by his uncomfortable experience on the journey, finds himself in Petrograd, settled in the most expensive and most crowded hotel in the city. After a day or so of discomfort, he is ripe for complaints, and sees only the bad side of things. Overwhelmed by the large numbers of rubles asked for commodities, he forgets that a ruble is only 14 cents, and that many commodities being imported are bought by traders on the dollar, not the ruble basis, and have to be sold accordingly.

It is an economic fact that in an isolated community, commodities eventually equalize in their relative price and therefore even home-made products will climb up to their proportional cost. The big Russian cities, now that the system of communication is out of order, are isolated communities. Recognizing this fact and the depreciation of the ruble, and comparing the prices obtaining in the large Russian cities with the prices of, say Paris, which has much better transportation facilities, one can see that "the devil is not as black as he is painted."

In cities of smaller population, and at inland localities of Russia, conditions are different. Food is plentiful, the exorbitant costs of Petrograd are almost unknown, and even luxuries can be obtained at moderate prices. My brother, now attending the University of Tomsk, the capital of Siberia with about 100,000 population, lives comfortably on 150 rubles (about \$22) per month. In many Siberian and some Russian cities, even at present, meat can be obtained at 6 cents per pound.

From all this it follows that the conditions of living and prices in Russia generally (not the large congested cities that constitute about 3% of Russia) are as good as, if not better than, in other warring countries.

The industrial situation is bad, as might be expected when all the man-power and skilled labor are withdrawn. The new government realizes this and is already withdrawing all skilled men from the army and placing them

where they will be most useful. To increase the number of skilled and trained men, the Government is issuing a call for all Russian engineering and medical students abroad to come home to complete their education, full credit being given to them for the work done abroad. This is a radical departure from the practice of the past, when even a graduate of a foreign university usually had to begin his work over again in Russia almost from the freshman year.

Labor troubles occur frequently in Russia, but so they do in other countries where the position of labor is much better, and where people have had a long experience in organization and self-government. The present misunderstandings between labor and capital are temporary. Things are already straightening up and much quicker than expected by the most optimistic of those who knew better than to expect an immediate settlement of problems confronting the world for the last 50 or 60 years.

Many local labor organizations, especially those removed from Petrograd, the chief source of trouble, are withdrawing from the influence of the central body and doing their best to stabilize conditions. Recently when an order for a railroad strike as a protest against the Moscow conference was called by the Petrograd Council, practically all local unions disregarded the order, and only the Moscow-Petrograd non-military traffic was interrupted. As to the closing of industries or inability to run plants without Government subsidies, it is mostly due to purely local factors of transportation, supply, management, and the pre-revolution relations between Capital and Labor, the latter being sometimes the most important.

It takes a man of great adaptability to concede suddenly the fact that labor is something more than chattel, and that pre-war conditions of work and wages are no longer possible. On the other hand, the laborer when made to understand his power and given an opportunity to exercise it, will be the more aggressive, the worse his conditions were before the revolution. Where there were fair labor conditions and where the management did not act hastily or resorted to drastic measures the worst of misunderstandings were settled to the satisfaction of both parties.

I know of a case where the workmen appropriated a munitions plant from the owner, and appointed him general manager, in recognition of his good management of the men, as well as his executive ability. Appreciating the psychology of the moment, the owner did not shut-down the plant, and now after things have been thought and talked over he is still its owner and operates it to his own, the employees, and the Government's satisfaction.

The political condition is improving, in spite of all the reports in the press, and the so-called eye-witnesses. These reports certainly have a foundation to them; but while one sees and hears the soap-box orator, and the demonstrations, which are growing smaller in number and importance, he hardly can notice, without especially looking for it, the silent constructive work.

Just now Russia is like a bottle of good wine that was

kept tightly corked for centuries. The first to appear is the foam and the longer the time of 'seasoning', the more foam must escape. But there is good wine and plenty of it in Russia. The silent creative work of the best people of the country is felt already. The Government grows stronger every day. The extremist is losing his influence over the Council of Workmen and Soldiers and the Council has not as much power as it had a few months ago. Just today I read in the papers that the Government proclaimed martial law in Finland, and refused any financial help to Ukraina, the provinces that, supported by the Russian extremists, insisted on becoming independent immediately. Could a weak government do this?

The fear that private property will be abolished in Russia may be dismissed. The Russian peasant demands land, that is, he wants to become a proprietor himself. It is hardly probable that he will vote against his own desire. There may, and probably will be, a distribution of crown-lands and other large land-holdings, and the adoption of the leasing system in mineral development, but that is as far as it may go.

Graft among officials, so common during the old regime, is dying out wherever new men are substituted for the old 'tchihovnik' and Mr. Winchell must have had queer luck to witness so many cases personally.

Summing up my statements, I would like to say that in studying Russia and Russian conditions, especially at the present time, one must not be impressed too much by what he sees or hears. Russia is a land of great possibilities and their realization is much nearer than one may expect. If the United States wants to help Russia and to profit by this help, it must start now, when there is need for help and when the field is clear. Germany will not give in easily. She is ready to step in any moment to re-establish her economic ante-bellum status in Russia. Do not give up Russia as hopeless, for the present. The successful person is he who does the thing while other people are deciding whether or not to do it, and in nine cases out of ten, 'the early bird gets the worm.'

## Freight-Rates on Drill-Steel

The Editor:

Sir—A vivid object has come under my observation in relation to another thrust at the high cost of mining. While the West Coast enjoyed the competition of ocean transportation from the Atlantic ports, the mines were able to secure a freight-rate on mine drill-steel of 45c. per 100 lb. During this time the railroads were making a rate of 80c. on the minimum car of 40,000 lb., and Pittsburgh, Pa., had a rate of 60c. on an 80,000-lb. minimum. When the railroads asked the Interstate Commerce Commission for an increase of 15% in transcontinental rates, during the latter part of 1916, the rates on mine drill-steel, classified as bar-steel, were increased to 90c. on the 40,000-lb. minimum, and 85c. on the

50,000-lb. minimum, with a 75c. rate on the 80,000-lb. carload. Less than carload rates were \$1.50 per 100 lb. During all of this time the classification was ambiguous, and with the water competition there never was any attempt made toward a close inspection or classification of mine drill-steel other than as bar-steel. The last trans-continental west-bound freight tariff, No. 1-P, issued February 20, 1917, effective April 16, 1917, placed the 20 and 25-ton minimum on bar-steel under the classification of structural iron and steel, which left only the 80,000-lb. minimum at the 75c. rate on bar-steel, under the iron and steel classification. Under the structural iron and steel articles, item 1514, containing the two lower minimums (40,000 and 50,000 lb.), specifies . . . "bars, including corrugated and twisted bars." Item No. 1522, under the heading of iron and steel articles which carry the 80,000-lb. minimum, specifies bar-iron or steel, including corrugated or twisted bars. The only difference between the first two minima and the third is that the first two are under the sub-heading of structural iron and steel, and the third under iron and steel articles. While it is easy to recognize the distinction, the fact remains that the railroads have allowed mine drill-steel to come through under the structural iron and steel classification, which contains the two lower minima, and have been billing it at the corresponding rates when shipped as bar-steel, without any attempt at close inspection, thus establishing a long precedent in favor of the 20 and 25-ton carload rate. From my observation, it all depends on the classification placed by the inspectors, and as cruciform drill-steel is a corrugated steel and has been so construed, the point upon which the railroads are now deciding is a direct discrimination against this class of steel to that which it formerly enjoyed. Carloads of steel have been received where an endeavor has been made to assess the 75c. rate on the 80,000-lb. minimum, and the railroads have corrected their assessments to apply to their 85c. or 90c. rate on the lower minimum, according to the quantity which the car contained over the 20 or 25-ton carload. Just to show how ambiguous the classification is: 999 agents throughout the West Coast, if required to give the rate on bar-steel (as there is no other classification for mine drill-steel other than bar-steel), would quote one of the three minima to which I have above referred. This is also a direct discrimination against the mills' entire output of which, or at least 90% of it, is mine drill-steel. Unless they ship in 80,000-lb. cars they would have to compete with mills that ship all grades of steel, including a portion of mine drill-steel. This would make a rate of \$1.50 against 75c. It seems to me that mine drill-steel should be descriptive so that it would be impossible for any one firm to make up a car including mine drill-steel, thus securing a lower rate in discrimination against another firm shipping all mine drill-steel and having to pay the higher rate. The Interstate Commerce Commission has decided that so far as present rates go, the 20 and 25-ton cars to the Pacific Coast will be eliminated from the tariff, which automatically increases the rate from 75c. to \$1.50 per 100 lb. in

amounts less than 80,000 lb. Some action should be taken on the part of the mining companies to secure a hearing before the Interstate Commerce Commission to secure for themselves an equitable rate on mine drill-steel, and not permit the railroads at this time to take advantage of such ambiguities for setting up an arbitrary tariff. As things now are the lack of proper classification causes an assessment of \$600 on a 50,000-lb. carload of steel instead of \$425 as formerly. The Atchison, Topeka & Santa Fe have the matter under advisement with the Transcontinental Freight Bureau at Chicago, and the outcome of the decision is awaited with great interest.

Trusting that the facts I have presented will arouse action by mining people that will secure proper representation to prevent an arbitrary increase in freight rates.

H. D. STALEY.

San Francisco, October 22.

## Tungsten

The Editor:

Sir—It has occurred to me that many shippers of tungsten ores do not realize the position of the tungsten market regarding quality, and it might be useful to give an idea of what the market requires. Different buyers make different specifications. The main division as to quality depends upon the method of treating the ore, either by a chemical process, by an electrical process, or by a semi-wet process. Prior to the War, most tungsten ores were treated by the chemical process, but at the moment of writing, the preponderance of users in the United States reduce the ores by electrolytic methods.

In the electrolytic process, copper, tin, and phosphorus are the most objectionable impurities, and it is almost impossible to sell to anyone employing the electrical process any material containing in excess of 0.05% tin, 0.05% copper, and 0.04% phosphorus; thus ore that is free from these impurities is put in the highest class, and naturally commands the top-market price. Ore that does not meet these specifications is therefore called 'off-grade,' and while in a rising market it is sometimes possible to sell ore with impurities slightly above the percentages given, it is exceedingly difficult to sell it at good prices in a sluggish or steady market.

In the chemical process, tin or copper or even phosphorus can be eliminated, and therefore, the chemical-process buyers are not so particular as to the impurities, but inasmuch as the number of these producers is limited, all the ore coming on the market and containing tin, copper, and other impurities is offered to these few producers, who naturally find an abundance, and are not prepared to pay top-market prices. As a matter of fact, they have been able to make their price, and while for high-class ore the market is often a seller's market, for off-grade ore it is almost invariably a buyer's market. The buyer's idea of price governs the market, otherwise off-grade ores cannot be got rid of and will ultimately

reach the buyer still cheaper than if his price is accepted as and when the lots come on the market.

Inasmuch as supply and demand are at the present moment balancing themselves, it is easily understood that buyers even for the chemical process prefer to take ores from which they have not the trouble of extracting the impurities. Ores containing deleterious matter have to be sold at heavy discounts from the regularly established price. I have handled a considerable quantity of tungsten ores amounting to thousands of tons already this year and have not yet had a single lot of tungsten ore unsold, though some of them assay as high as 11% tin. Of course, where tin is contained in the ore in such a large percentage, it would be advisable to have it extracted either at the port of shipment or in New York, if arrangement to that end could be made. Such extractions would prevent a sale prior to the result of the extraction being known.

CHARLES HARDY.

New York, November 1.

## A Plea for Labor

The Editor:

Sir—I had a mind not to subscribe for your paper at all, yet after thinking about it over-night, I believe I shall do so. On page 561, issue of October 13, in an article from Treadwell on the labor-supply, I read: "This is a good policy.....to get more work out of a man." Can the gentleman who penned those lines really have any just cause for complaint if the men adopt a method that makes it possible to get more money out of the company "than can be gotten in any other way?" Is it not because of the extra 50 cents that more work is done and not because of "the policy" of contracting? Could not the foreman take the place of the contractor, and in that case would not the increase amount to just 50c. anyway? To be sure! But the idea is that the contractor will do the driving, relieving the company of this disagreeable phase of getting the work done. Not long ago, while talking to a very fair conscientious man about the kicking against working conditions he had heard among the miners, I remarked that I believed in giving them everything that was fair, and perhaps a little bit more, to be sure; then, if they still kicked, discharge them instantly, and with a clear conscience. I said, "Make a man's work as easy to do as possible, for the easier he can do his work, the more work he will do." The gentleman said "The more work he *must* do!" Like the writer of this article, he believes that force is necessary; he does not give the miner credit for ambition, a sense of justice, or the desire to give the company a square deal. The late Mr. Taylor, consulting engineer to the Midvale Steel Co., said: "By getting the goodwill of the worker, he will do more work for you voluntarily than all the bosses on earth can force him to do." Very well! Mr. Emerson lays much stress on his thirteenth principle, 'The principles of personal efficiency'; it is the square deal, he says. "The best way to get the square deal for yourself is always to give it

to the other fellow." Language was made to conceal thought, as some one has said. It requires a very brainy man, a skilful talker, to make me believe what he does not believe himself. To try to convince a man you have perfect confidence in him, when in the back of your head is that deep-seated idea that force is necessary to compel what may be called a fair day's work for a fair day's wage, is almost impossible. Perhaps it is so, but if it is, why blame the I. W. W., if he is convinced of the truth of it too? Enclosed find clipping from the Los Angeles 'Times,' 'Edgerton Discusses Federal Ownership,' especially paragraph headed 'Transition Period.' The proposition is this: either men can be governed by reason, by justice, and by fairness, or they cannot. It is either the American idea of government or the German. The battle royal between these two conflicting ideas is on, and must be fought to a finish ere the sword is sheathed in Europe. Should the War last two or three years longer, I expect to see American army and navy officers in command of the Allied military and naval forces; an American field-marshal and an American admiral outranking all other admirals. General Goethals did a very bad thing for the private control of big interprise when he decided to turn down the contract method on the Canal, and gave the socialists cause to rejoice. Another thing, the officers of all the armies at war are climbing out of the trenches into uniforms with shoulder-straps, consequently the armies are more democratic than ever. When reforms are demanded, backed up by a victorious army, democratic to the core, what will happen? Why, Sir, there would be nothing to do but get out of the way of that reform and that army pushing it along. Have you ever noticed how much good can be done by a kind word? How it can put courage and hope into an almost broken heart? Did you ever try having confidence in people and telling them of it? Have you ever, as Daniels has done, when reviewing the findings of a court-martial, suggested to the Judge Advocate, "Put yourself in his place." Do you remember that the first workingman was a beaten brother, a slave, conquered in battle, probably with a war club or a stone hatchet, tamed by hunger and blows to such an extent that he obediently worked for his conqueror to preserve his life? What wonderful ideas have caused the abolition of such conditions, and how far have we gotten from the first master and servant. This great advancement is not due alone to the struggles of the slave to be free; a great deal of credit is due to the minds that were imbued with lofty ideas of justice. That's what Americanism means. Liberty and justice to the oppressed!

J. F. HARRINGTON.

We discuss this letter on another page.—EDITOR.]

# Hydro-Metallurgy of Copper Sulphides

By A. E. DRUCKER

**INTRODUCTION.** The hydro-metallurgical treatment of table and flotation concentrate on the spot in a good many cases has proved to be more profitable than trans-

of mining companies that in the beginning shipped gold and silver-bearing concentrate to a smelter, paying in some cases exorbitant freight rates and smelting charges,

ACID-PROOF DOER THICKENER, MERRIMAC CHEMICAL COMPANY

porting to a smelter. The smelter generally gains at the shipper's expense mainly through the extraction of the metal and the moisture deduction. A large number

finally adopted a hydro-metallurgical process at the mines with the result that large additional profits were realized. The saving on drying, bagging, carting, and

transporting ranged from \$5 to \$20 per ton plus a 3 to 7% increase in the recovery of the gold. A saving also was made in certain cases on the cost of treatment. The following list includes some important companies that have made this change:

	Tons treated	Metal contained
Oriental Consolidated, Korea.....	2400	gold
Alaska Treadwell, Alaska .....	3000	"
North Star, California .....		"
Esperanza, Mexico .....		"
Waihi, New Zealand .....	500	silver-gold
Frontino & Bolivia, Colombia.....	150	gold
Goldfield Consolidated, Nevada (preliminary roast) .....	2400	gold-silver
Ivanhoe, Australia (preliminary roast) ..	1950	gold
Golden Horseshoe, Australia (preliminary roast) .....	2000	"
Oroya-Brownhill, Australia (preliminary roast) .....	1000	"
Lake View Consols, Australia (preliminary roast) .....	1800	"

The cost of treatment per ton at the above plants varies from \$2 to \$6, while the recovery of precious metals is from 90 to 97%. The successful treatment on the spot has been developed during the past ten years. There is equally as great a field with a similar, acid-leaching, treatment in the case of copper sulphides, and I believe that hydro-metallurgy will become eventually as important to the copper industry as cyanidation has been to gold and silver miners. Present-day smelting methods of extracting copper from table and flotation concentrate will be gradually replaced, except in a few special cases, by combined roasting and leaching, producing electrolytic copper direct in marketable form.

In the consideration of the acid-leaching process the first factor is the character of the concentrate. The table and flotation concentrates obtained from the porphyry copper ores at Bingham, Globe, Ely, and Miami should be amenable to acid-leaching after a preliminary roast. This concentrate contains 10 to 28% of copper, 16 to 23% iron, 22 to 32% sulphur, and 18 to 28% insoluble, and with the exception of the Bingham concentrate there is no appreciable amount of gold and silver.

**TREATMENT.** The following is a general outline of the treatment which I suggest for the porphyry sulphides or similar material amenable to acid-leaching. No attempt has been made to go into the details of roasting, leaching, and electro-precipitation. As a general rule porphyry concentrate contains practically no zinc, lead, silver, or gold, and therefore is particularly suited to roasting and acid-leaching. Copper is one of the most readily soluble of all metals, and most easily precipitated electrolytically. Small amounts of zinc present would not affect the operation materially. The zinc problem has been satisfactorily solved at Anaconda. Where gold is present to the extent of \$2 to \$3 per ton of concentrate, as in certain cases at Bingham, Utah, acid-leaching would not recover this, and it is questionable if smelting could be replaced advantageously.

**ROASTING.** A multiple-hearth muffle roasting-furnace has been successfully employed at low temperatures for sulphate-roasting, and in some cases as high as 80% of the copper was rendered soluble in water as sulphate. The total soluble copper has been increased to over 95% by the use of a weak acid-solution. If the sulphides are roasted so as to make about 50% of the copper soluble in water, the remaining copper may be extracted with the regenerated acid resulting from the electro-deposition of this metal. For every pound of copper deposited 1.54 lb. of acid is regenerated. With such regenerative methods no additional acid need be provided and no fouling of solutions is likely to occur. The Chile Copper Co. offers one example. The sulphurous gases from a roasting-furnace have been applied direct to the wetted crude ore or as a spray to ore pulp, producing the necessary acid solvent. This is a means of dispensing with the usual expensive acid-making plant. The sulphatizing of the wetted roasted sulphides with sulphur gases, followed by leaching with the regular solutions from the plant, is one cheap and effective way of getting the copper into solution. The elimination of sulphur from the sulphides is accompanied by the evolution of considerable heat generated during its oxidation. Concentrate containing as low as 15% sulphur has been roasted to a certain point in multiple-hearth furnaces without the addition of fuel preliminary to smelting. On concentrate high in sulphur, that is, from 20 to 35%, the roasted material may be reduced as low as 7 to 9% sulphur without the use of fuel. Reducing this 7% down to 3 or 2% requires extra fuel.

For a sulphatizing roast, the temperature should not exceed 600 to 650°C. Copper sulphides are not particularly sensitive to high temperatures, and if sintering or fusion occurs, it is impossible to get a satisfactory extraction. The product, when well roasted for acid-treatment, will contain from 3 to 4% of sulphur as sulphide, containing practically all the copper in the form of sulphate or oxide, and all the iron in the insoluble ferric state. The Wedge multiple-hearth type of furnace is being successfully used for the chloridizing roast of silver and copper ores. The furnace may be fired with oil, gas, coal, or wood, if a more thorough roast is desired for hydro-metallurgical work. In the case of fuel oil, it can be injected into the lower finishing hearths as desired. If solid fuel be used, the enclosed fire-box type may be employed. The fuel consumption with wood or coal usually varies between 9 and 16% of the weight of the concentrate, when roasting to less than 1% sulphur remaining in the form of sulphide. In roasting sulphides down as low as 7 to 10%, fuel is not ordinarily necessary. At Kalgoorlie, Western Australia, the following results were obtained on concentrate:

Company	Raw	Sulphide sulphur		Wood	Furnace
		%	Roasted	used weight	
Lake View .....	25-30	0.35		9.8	Edwards
Oroya-Brownhill .....	35	0.20		16.0	Merton
Ivanhoe .....	27	0.11		14.0	Edwards

COUNTER-CURRENT ACID-LEACHING PLANT, DAVISON CHEMICAL COMPANY

MECHANISM FOR CONTROLLING LEACHING-VATS, DAVISON CHEMICAL COMPANY

I believe that with a modern Wedge or McDougall furnace concentrate or copper sulphide could be de-sulphurized to 1% sulphide sulphur with a consumption of 6 to 8% by weight of wood or coal. At the Goldfield Consolidated, Nevada, nine gallons of crude oil is required per ton of concentrate, or 3.3% of the weight. The raw concentrate contains about 19% S, and the roasted product 0.15% S. The cost of roasting sulphides varies from 25c. to \$1 per ton, depending upon the ton-

LEACHING AND PRECIPITATION. After roasting the sulphides, the copper should be in the form of sulphate and oxide, although some sulphide will remain, as a complete roast in this particular case is not desired. The roasted material is then treated by the ordinary sulphuric-acid leaching process. The oxide of copper is readily soluble in weak-acid solution, and to a certain extent by the ferric sulphate formed by air-agitation of the pulp and by the electro-deposition of copper from

ROASTING-PLANT, GOLDEN HORSESHOE ESTATES CO., SHOWING EDWARDS FURNACES

PLANT FOR LEACHING COPPER CALCINE FROM PYRITE-BURNERS

nage, the degree of roasting, the type of furnace, the fuel used, and other local conditions. At Butte and Garfield costs have been as low as 25 to 35c. per ton for incomplete roasting in McDougall furnaces, reducing the sulphur down to 7% prior to smelting. I see no reason why the cost of this preliminary operation to acid-leaching with a well-designed roasting-plant to treat 100 to 200 tons of sulphides per 24 hours would not average about 50c. The cost of a modern roasting-plant of the Edwards, Ridge, or the Wedge and McDougall multiple-hearth type, will vary between \$600 and \$800 per ton of daily capacity for de-sulphurizing.

the solutions. Copper sulphate is practically all soluble in water, especially when some acid is present. After a proper roast it is an easy matter to get the copper into solution very completely, but, as all metallurgists know, the most difficult part of the process is to precipitate the metal efficiently and economically in a marketable form. Most of the improvements in the future will be in the electrolytic deposition of the copper from these complex solutions. Considerable advancement has been made with this at Anaconda and at Chuquicamata, Chile. If there is lime in the original ore, it will not be present in the concentrate in injurious amounts. The same is

largely true with other impurities which usually cause a loss of acid and also contaminate and foul the electrolyte, causing trouble in the electrolysis and producing impure copper. I realize that it is not all smooth sailing with the acid-leaching process and especially with

At the present time the electrolytic process for the recovery of copper from acid solutions offers economic possibilities, especially when one considers the present cost of re-melting blister copper into anodes and refining these. The regeneration of the acid solvent to a

WEDGE ROASTING-FURNACE

electric precipitation, but I do say that the problems are no more complex and difficult than with the cyanide-leaching process, which during the past thirty years has been perfected to a high point. There are no such complex solutions to deal with as compared with those resulting from cyanide leaching of mixed sulphides.

large extent is a most important consideration. Sulphate solutions, resulting from acid leaching in practice, will require a voltage of about 1.5 to 3, with a current density of 5 to 12 amp. per sq. ft. In practice it has been found that one to two pounds of copper will be deposited per kilowatt-hour, regenerating the acid.

With concentrate containing considerable slime and material finer than 200 mesh, the ordinary sand-percolation treatment in vats would not give a satisfactory extraction. It has been found on the Rand, and in other places, that a sand-charge containing more than 2 or 3% of slime will not give the best result. The presence of slime is detrimental when it goes above that amount, and the extraction will gradually fall as the amount of slime increases. The most efficient and profitable method for leaching roasted concentrate finer than 150 mesh would be air-agitation of the pulp of a consistence of 1 to 2 or 1 to 3, in Dorr agitators followed by dilution with the 5 to 10% acid-solution, and with counter-current decantation in a series of Dorr thickeners. A water-wash would be used in the last thickener. I think that there would not be any need of a vacuum or pressure-filter at the end of this operation for removing the last traces of dissolved copper. This part of the operation would be identical with the latest practice in cyanide counter-current decantation, which has proved so successful on gold and silver ore. For treating the heavy material, coarser than 150 mesh, we have the Dorr agitator, followed by the multiple-deck washing classifier, which is suitable for counter-current leaching and washing. A four or five-deck machine could be used for this purpose, or several standard Dorr classifiers operating in series. All machinery used in leaching must be acid-proof.

Costs of construction of a plant vary largely in different parts of the United States, depending on the cost of material, transportation, labor, and other local conditions. A plant consisting of Wedge furnaces, acid-recovery equipment, Dorr classifiers, agitators, and thickeners, and with clarifying-filters and the necessary electro-precipitating plant, would cost from \$1500 to \$1800 per ton of concentrate treated per 24 hours. The cost for treatment per ton of concentrate would vary between \$3 and \$5. Copper extraction would vary from 90 to 95% or more, depending on the degree of roasting, time of treatment, and the percentage of copper in the concentrate. There is reason to believe that, within the next few years, hydro-metallurgical methods, with electrolytic deposition, will play an important part in extracting marketable copper direct from concentrate on the spot. Smelting methods gradually will be replaced to a large extent by the more economical wet methods. Copper, zinc, gold, and silver-bearing concentrate are nearly all amenable to the wet methods after roasting. In many cases the marketing concentrate costs in the aggregate from \$10 to \$40 per ton. This includes freight, sampling, smelter-charges and deductions, electrolytic refining, and selling. Under such conditions the leaching of copper offers great possibilities at a cost that should not exceed \$3 to \$6 per ton.

DOMESTIC prime white floated barytes now brings \$30 per ton, and off-color grades sell at \$22 to \$24. The foreign competition is practically eliminated on account of lack of shipping facilities.

## Mining Dividends and Income Tax

An income-tax ruling just promulgated by the Treasury Department will interest stockholders in a number of mining companies that have adopted the plan of declaring dividends out of reserve set aside to meet depreciation and depletion of property. The ruling follows:

"Referring to the practice of certain corporations of declaring dividends out of reserve set aside to meet depreciation and depletion of property, and of advising stockholders that such dividends represent a distribution of capital assets, your attention is directed to the ruling made herein as follows:

"All such dividends received by stockholders declared out of such reserves, accumulated subsequent to March 1, 1913, constitute income to the stockholder under the act of September 8, 1916, and must be accounted for in returns of net income.

"A stockholder's investment is in the stock of a corporation. If he disposes of his stock for more than its fair market value on March 1, 1913, or its cost if acquired since that date, the profit realized must be returned as income; if he disposes of it at a loss, the loss sustained is deductible from gross income within the limits of the taxing act. In computing the profit or loss sustained, there must be taken into account dividends paid from reserves accumulated prior to March 1, 1913, which were not returned as income for the year in which received, under the provisions of the act of September 8, 1916."

The gist of this ruling is to subject to the income tax those dividends that have been called a distribution of capital assets. Hitherto it had been supposed in some quarters that dividends representing distribution of capital were not subject to the tax. Such dividends have been declared by Utah, Chino, Nevada Consolidated, Ray Consolidated, and St. Joseph Lead companies.

AN OCCURRENCE of nickel ore near Perto da Villa de Livramento in Minas Gerães, Brazil, is the subject of a paper by Horace E. Williams, published by the Serviço da Agricultura e Mineralógico do Brazil. The property is 261 kilometres from Rio de Janeiro, and 55 kilometres north-east of Pico de Itatiaya, in the municipality of Turvo. The region is composed mostly of ancient gneissoid rocks, while the chief mountain-mass in the vicinity consists of nepheline syenite. This is intruded by a basic rock in which the chief constituent is olivine, and it is in this rock that the nickel is found. The basic intrusive has been extensively altered to serpentine, and the outcrop contains the nickel as garnierite, much of which will assay  $3\frac{1}{2}\%$ , and some of it as high as 8 to 15%. Mr. Williams attaches minor importance to the deposits so far explored as a basis for a considerable nickel industry, but recent explorations have indicated that this serpentinized belt may yield important amounts of chrome ore, with nickel ores as a valuable accessory.

COBALT oxide is in good demand, and is selling at \$1.50 to \$1.60 per pound.

# Proportions for Cement Mortars and Concretes

By J. A. KITTS

\*THE VOID THEORY. As an initial step in the determination of the laws of concrete mixtures, it is more important that one combination of materials be studied thoroughly in a great number of progressive proportions with enough test-specimens of each mixture properly to reduce the errors of the average results, than it is to study many combinations of a large number of

ren of positive results. Some other methods must be used if we are to obtain accurate knowledge of the laws governing mixtures.

The void theory of proportioning has been known for a number of years, but has not been given proper consideration, and the fundamental principle has not been appreciated. This lack of consideration has been because the theory, as generally known, defined the proportions for maximum strength rather than for maximum efficiency or maximum strength in proportion to cost. A broad statement of the void theory is as follows:

The proportion for maximum efficiency of a mortar

TABLES I AND II. PROPERTIES AND SCREEN-ANALYSIS OF SAND IN WITHEY'S TESTS

Sand No.	Weight per Cubic Foot, lb.	Specific Gravity.	Void, per cent.	Silt, per cent.	Absorption, per cent.

materials with only a few mixtures and a few test-specimens of each combination.

With a certain combination of cement, sand, and rock, we find that an arbitrary 1:2:4 mixture shows greater strength in proportion to cost than a 1:3:6 mixture, and that a 1:2½:6 mixture is more efficient than either. It is probable that no one of these arbitrary mixtures is the most efficient and it is apparent that any number of arbitrary mixtures may be made and tested with the common result of producing more confusion than knowledge of the laws of mixtures. The arbitrary method of proportioning has been bar-

or a concrete is controlled largely by the proportions of voids in the respective aggregates.

This aspect of the void theory is the basis of the following considerations.

MORTARS. A mortar is a mixture of sand, cement, and water in various proportions. The question of scientific interest is: What determines the proportions for maximum efficiency?

Sands vary in physical, chemical, and mechanical structure, causing a variation in the specific gravity and percentage of voids, and the last two properties cause a variation in the weight per cubic foot or aggregate specific gravity. An important consideration in the study of a large number of mortars from a large number of aggregates is that of comparison. A study of the characteristics of various sands will show that mortars are not comparable either in arbitrary weight-proportions or in arbitrary volumetric proportions. What then determines the conditions for comparison of the mortar from one sand with that from another? An analysis of the results indicated in M. O. Withey's test of mortars throws considerable light on the two pre-

\*Paper presented at the annual meeting of the American Society for Testing Materials.

ceding questions.<sup>1</sup> In these tests mortars were made in 1:2, 1:3, 1:4, and 1:5 weight proportions and the following tests made: Unit tensile strength; unit compressive strength; leakage of water through specimens 2 in. thick, with pressures of 10 and 40 lb. per sq. in.; density; yield; and compressive strength in proportion to cost. Tables I and II show the physical and mechanical characteristics of eleven of the sands used in these tests.

TABLE IV. RATIO OF VOLUME OF CEMENT PASTE TO VOLUME OF VOIDS IN SAND FOR SIMPLE WEIGHT-PROPORTIONS

Sd. 4.....	1.13	0.75	0.56	0.45
Sd. 5.....	0.91	0.61	0.46	0.37

Tables III and IV show the variations of the volumetric and void conditions common to simple weight-proportioning.

Table III is computed by the following equation:

$$\frac{\text{Aggregate volume sand}}{\text{Aggregate volume cement}} = \frac{\text{Weight proportion sand}}{\text{Weight proportion cement}} \times \frac{\text{Aggregate specific gravity cement}}{\text{Aggregate specific gravity sand}} \quad (1)$$

$$\text{Aggregate specific gravity}^2 = (1 - \text{proportion of voids}) \times \text{specific gravity} \quad (2)$$

$$= \frac{\text{Weight, in lb. per cu. ft.}}{62.5}$$

$$= 110/62.5 = 1.76 \text{ for cement}^3$$

Table IV is computed by the following equation:

$$\frac{\text{Volume of cement-paste}}{\text{Volume of voids in sand}} = \frac{\text{Aggregate specific gravity of sand}}{\text{Aggregate specific gravity of cement} \times \text{weight proportion of sand} \times \text{voids in sand}} \quad (3)$$

$$\frac{\text{Volume of cement-paste}}{\text{Volume of voids in sand}} = \frac{1}{\text{Volume proportion of sand} \times \text{proportion of voids in sand}} \quad (4)$$

Table III shows that the volumetric proportions correspond to the 1:2 weight proportions vary from 1:1.77 to 1:2.41, the 1:3 weight from 1:2.65 to 1:3.62 volume, 1:4 weight from 1:3.54 to 1:4.82 volume, and the 1:5 from 1:4.42 to 1:6.03. Table IV shows the proportions

of voids in the sands filled with cement-paste varying from 0.91 to 2.03 for the 1:2 weight proportion, from 0.61 to 1.35 for the 1:3, from 0.46 to 1.01 for the 1:4, and from 0.37 to 0.81 for the 1:5 proportion. Nothing could better illustrate the fallacy of the practice of comparing work-sands with standard sand in 1:3 weight proportions.

Neither is there a basis of comparison in a fixed volumetric proportion. In 1:3 volumetric proportions

TABLE V. RATIO OF VOLUME OF CEMENT PASTE TO VOLUME OF VOIDS IN SAND, FOR VOLUMETRIC PROPORTIONING

the proportions of the voids in the sands filled with cement-paste would vary from 0.73 to 1.20 for the eleven sands as shown in Table V. It must be admitted, from both scientific and from practical considerations of a mortar, that an important function of the cement is to fill the voids in the sand; and it cannot be expected that a mortar in which the volume of cement-paste is equal to only 73% of the volume of voids in the sand, is comparable with one where the cement-paste is equal to 120% of the voids.

Assume, for example, that six mortars of a certain sand and cement are made in which the ratio of the volume of cement-paste to the volume of voids in the sand has, respectively, the values 0.50, 0.75, 1.00, 1.50, 2.00, and 3.00. It is reasonable to anticipate that the strength of the mortars will increase at a rapid rate until the voids in the sand are filled with cement-paste, after which the strength will increase at a lesser rate until the sand-particles are so widely separated by the cement-paste that the strength of the mortar will approximate closely the strength of the neat cement. In other words, as the cement-content is increased, the rate of increase of strength is greater before the voids are filled than it is after the voids are filled. Also in some finite proportions the strength of the mortar approximates the strength of the neat cement. Fig. 1, which shows the compressive and tensile strengths and the strength in proportion to cost for sand No. 10, plotted against the void-filled ratio, illustrates these assumptions very well. This sand, unfortunately, is the only one of this series of tests which had one mixture (the 1:4 by weight) where the volume of cement-paste was approximately equal to the volume of voids in

<sup>1</sup>M. O. Withey, 'Tests of Mortars Made from Wisconsin Aggregates,' Proceedings, American Society for Testing Materials.

<sup>2</sup>In an article on this subject published in WESTERN ENGINEERING for August 1915, I called this "apparent specific gravity," for want of a better term.

<sup>3</sup>110 lb. of cement makes 1 cu. ft. or normal-consistence paste

the sand, and which had more than one mixture where the volume of cement-paste was greater than the volume of voids in the sand.

Fig. 2 shows the compressive strengths plotted

FIG. 1. VARIATIONS IN STRENGTH OF MORTAR FROM SAND No. 10  
IN PROPORTION TO VOID-FILLED RATIOS

against the void-filled ratio. The curve of averages supports the assumption as to the rate of increase of strength. The curve is fairly uniform, and would appear to indicate that the void-filled ratio has a similar effect on all the sands. This, then, appears to estab-

FIG. 2. VARIATION IN STRENGTH OF MORTARS IN PROPORTION TO VOJO-FILLED RATIOS

lish the principle that the properties, strength, and other characteristics of mortars, are properly comparable on the basis of the void filled ratio.

The final and most important consideration of a mortar is the strength in proportion to the cost. This may be expressed as an 'economy factor,' equal to the compressive strength in pounds per square inch divided by the cost of the mortar in dollars per cubic yard.

This factor may be expressed by the following equation:

$$\text{Economy factor} = \frac{\text{Compressive strength (lb. per sq. in.)}}{\text{Cost of mortar (dollars per cu. yd.)}} \\ = \frac{\text{Compressive strength} \times \text{yield}}{G_s + \frac{P_c \times C_c}{P}} \quad (5)$$

in which  $P_c$  and  $P_s$  are the volumetric proportions of cement and sand,  $C_c$  and  $C_s$  are the costs, in dollars per cubic yard, of cement and sand, and the yield is based on the volume of the sand as unity.

This factor is plotted in Fig. 10 of Withey's paper.

FIG. 3. VARIATION IN ECONOMY FACTOR IN PROPORTION TO VOID-FILLED RATIOS

mentioned above. The cost represents costs of materials only, cement being estimated at \$1.50 per barrel and sand at \$1.25 per cubic yard. In Fig. 3 these factors for all eleven sands have been plotted against the void-filled ratio. The average compressive strength of the cement used in these tests was less than 7000 lb. per sq. in. at 60 days. The economy factor for the neat cement mortar would then be approximately  $7000 \div 10.14 = 690$ .<sup>4</sup> The highest economy factor shown on the curve of averages is 860. This and the curve of averages indicate that the economy factor decreases when the void-filled ratio is somewhat in excess of 1.5. The results of these tests, therefore, indicate that the most economical mixtures lie between proportions giving a void-filled ratio from 1 to 1.5.

As an illustration, Fig. 3 shows that the most economical proportions for sand No. 10 is that in which the volume of cement-paste is equal to the volume of voids. From Fig. 1, it is seen that this proportion is 1

4It should be noted here that this value for the 'economy factor' of neat-cement mortar, as well as the other factors in Fig. 3, is based upon the assumption that 1 bag of cement gives 1 cu. ft. of cement-paste. If, as has been done in this paper, it is assumed that it requires 110 lb. of cement to make 1 cu. ft. of neat-cement paste, the cost of a cubic yard of cement-mortar would be \$11.85 instead of \$10.14, giving an 'economy factor' of 590.

cement to 3.58 sand by volume, giving a tensile strength at 60 days of 525 lb. per sq. in., a compressive strength of 4000 lb. per sq. in., and an economy factor slightly over 1000.

The equations for economical mixtures, as indicated by this series of tests, may therefore be written:

$$\frac{\text{Volume of sand}}{\text{Volume of cement}} = \frac{1}{(1 \text{ to } 1.5) \times \text{proportion of voids in sand}} \quad (6)$$

OR

$$\frac{\text{Weight of sand}}{\text{Weight of cement}} = \frac{\text{Aggregate specific gravity of sand}}{(1 \text{ to } 1.5) \times \text{aggregate specific gravity of cement} \times \text{voids in sand}} \quad (7)$$

If the properties of mortars from all sands vary with the variation of the void-filled ratio, the leakage, density, and yield should show similar effects for all sands. Fig. 4 shows the leakage of the various mortars plotted against the void-filled ratio; and this is another proof that the void-filled ratio is the proper basis of comparison of the properties of mortars.

FIG. 4. VARIATION IN LEAKAGE OF MORTARS IN PROPORTION TO VOID-FILLED RATIOS

**CONCLUSIONS REGARDING MORTARS.** 1. Sand-cement mortars are not comparable in simple weight proportions because of the wide variation in the corresponding volumetric-proportions and the variations of the void-filled ratios.

2. Sand-cement mortars are not comparable in simple volumetric proportions because of the wide variations of the void-filled ratios.

3. The void-filled ratio has a general effect upon the strength, permeability, and economy of a mortar and undoubtedly affects the density and yield.

4. An important function of the cement-paste is to fill the voids in the sand.

5. Sand-cement mortars are properly comparable on the basis of the void-filled ratios.

6. The economical proportions for sand-cement mor-

tars depend upon the void contents of the sands and may be expressed by equations 6 and 7.

7. The economy factor expresses the relative efficiency of mortars and may be determined by equation 5.

8. I do not find any general relation of silt-content, uniformity coefficient, and absorption to the efficiency of sands.

**CONCRETE.** Where concrete is made from either bank-run gravel, or a prepared concrete mix, and cement, it would be reasonable to expect the same general principles to apply as those previously stated for mortars. Where mortar is added to a coarse aggregate, such as rock, it is reasonable to assume that an important function of the mortar is to fill the voids in the rock.

A scientific test to determine the laws of concrete mixtures would be first, to determine the mortar of maximum density and the yield of mortar; second, to make progressive proportions of the mortar with the rock, using values of the ratio of the volume of mortar to the volume of voids in rock equal to 0.50, 0.75, 0.90, 1.00, 1.10, 1.25, 1.50, 2.00, and 3.00 with a view to determining that proportion giving maximum efficiency; and finally, to make additional progressive proportions, maintaining the ratio of fine to coarse aggregate of the 'efficient' proportion just determined, but increasing the amount of cement to 1.1, 1.2, 1.3, 1.4, 1.5, 2.0, and 3.0 times that used in the mortar of maximum density. The most economical proportions would be determined by the following equation:

$$\begin{aligned} \text{Economy factor} &= \frac{\text{Compressive strength in lb. per sq. in.}}{\text{Cost of concrete in dollars per cu. yd.}} \\ &= \frac{\text{Compressive strength} \times \text{yield}}{C_r + \frac{P_s \times C_s}{P_r} + \frac{P_c \times C_c}{P_r}} \quad (8) \end{aligned}$$

$P_c$ ,  $P_s$ ,  $P_r$  being the volumetric proportions and  $C_c$ ,  $C_s$ , and  $C_r$  the costs in dollars per cubic yard of cement, sand, and rock, respectively. The yield is based on the volume of the coarse aggregate (rock) as unity.

There are no test-data extant regarding the economical proportions of concrete. Some tests have been made by the U. S. Bureau of Standards using the void theory of proportioning in a limited way. The results of these tests will be analyzed in the following discussion and may throw some light on the subject.

The economy of any mixture depends largely upon the local cost of materials. If the cost of cement is twelve to fifteen times that of the aggregates, the economy of lean mixtures will be greater than if the cost of cement is comparatively lower. In Table VI, the economy factor for several 1:2:4 mixtures is compared with that of several void-theory mixtures, the factors having been computed by me from the results shown in Tables 8 and 12 of the Bureau of Standards paper.<sup>5</sup> The void-theory mixtures may be expressed by equations 9 and 10, the void-filled ratio (1 to 1.5) being 1.1 in every case both for the mortar and for the rock.

<sup>5</sup>Technologic Paper No. 53, U. S. Bureau of Standards.

The cost of the aggregates was assumed at \$1.20 per cubic yard and the cost of cement at \$12 per cubic yard. The yield of the various mixtures is necessarily assumed as unity, as it is not possible to approximate the yield closely by calculation.

It would appear from a study of this table, that the void-theory mixtures compare favorably with 1:2:4 mixtures, from the standpoint of efficiency. The two combinations of granite show the 1:2:4 mixtures as the most efficient. However, there are too few combinations to be conclusive.

In Table VII the economy factor is shown for various combinations of aggregates in three mixtures, 1:2:4, 1:3:6, and a void-theory mixture. In 33 comparisons, the ratios for the most economical mixtures are as follows:

Theoretical	1:2:4	1:3:6
18.....	15.....	.....
30.....	.....	3.....
.....	30.....	3.....

The ratio of cement to total aggregate is 1:8.12 for the theoretical mixture, compared to 1:6 and 1:9 for the 1:2:4 and 1:3:6 mixtures. The fact that the 1:9 arbitrary mixture is much less efficient than an average 1:8.12 theoretical mixture and that the 1:8.12 theoret-

ical mixture is somewhat more efficient than the 1:6 arbitrary mixture would appear to indicate that there is some basis for the void theory.

The 1:2:4 mixture generally appears to be an efficient one and the explanation may be the efficiency of the mortar. As the voids in sands are seldom below 33% or above 50%, the ratio of cement-paste to voids for the 1:2 mortar varies from 1 to 1.5, which corresponds to the limits previously determined for efficient

mortars. Rock seldom shows less than 35% or more than 50% of voids, so that in a 1:2:4 mixture the volume of mortar will vary from 1 to 1.5 times the volume of voids in the rock. A 1:3:6 mixture is seldom an

<sup>4</sup> Two combinations in common to both mixtures used.

efficient one because a 1:3 mortar is seldom efficient, few sands showing less than 33% voids.

CONCLUSIONS REGARDING CONCRETES. 1. An important function of a mortar in concrete is to fill the voids in the coarse aggregate.

2. The efficiency of a concrete mixture depends largely upon the efficiency of the mortar.

3. For economical proportions the volume of cement should be equal to or greater than the volume of voids in the sand but should not exceed  $1\frac{1}{2}$  times the voids in the sand, and the volume of mortar should be equal to or greater than the volume of voids in the coarse aggregate but should not exceed  $1\frac{1}{2}$  times the voids in the coarse aggregate.

4. The equations for economical mixtures may be stated as follows:

$$\text{Volume of sand} = 1$$

$$\text{Unit volume of cement} = (1 \text{ to } 1.5) \times \text{proportion of voids in sand} \quad (9)$$

$$\text{Volume of rock} = \frac{\text{Volume of sand} \times \text{yield of mortar}}{\text{Unit volume of cement}}$$

$$\text{Unit volume of cement} = (1 \text{ to } 1.5) \times \text{proportion of voids in rock} \quad (10)$$

5. The economy factor expresses the relative efficiencies of concrete mixtures and may be determined by equation 8.

GERMANS are said to be exploiting the Servian copper mines, of which one, the Bor, is of importance. They have also developed a source of copper in the Kielce district of Poland, where the existence of copper deposits had been known to the Russians but ignored. Meanwhile the copper mines of the Caucasus are being exploited on the Russian side.

## Leaching and Purification of Zinc Sulphate

By K. B. THOMAS

In the roasting of zinc concentrate in a Matthiessen-Hegeler kiln, a considerable quantity of dust is deposited in the flues that lead from the kiln to the dust-chamber, and in the dust-chamber itself; at times this amounts to an equivalent of 2 or 3% of the green ore charged in the furnace. The amount of flue-dust deposited in the flues of any type of furnace, with any kind of ore-charge, is mainly dependent on three factors, namely, (1) moisture-content of ore when charged, (2) fineness of the ore, (3) draft condition on the top hearth of the furnace. In the roasting of concentrate we have a very fine ore to handle, approximately 75% through a 200-mesh screen, and 90% through a 100-mesh screen; also we are using an ore which on account of its fineness needs a greater draft in the furnace than when roasting coarser ores. These factors account for the high percentage of dust formed. The large amount of dust produced, and the high zinc-content, necessitated the recovery of the zinc, and as practically all of the zinc was in the form of a sulphate, smelting was eliminated, and leaching was adopted, and found to be profitable as well as practical in every respect.

The analysis of a composite of different ores in use on furnaces is as follows:

	%		%
Zinc .....	45.5	Alumina .....	2.0
Iron .....	7.0	Manganese .....	1.0
Copper .....	2.5	Lime .....	1.0
Lead .....	1.0	Sulphur .....	27.0
Silica .....	11.5		

The analysis of a similar composite-sample of flue-dust showed:

	%		%
Zinc .....	31.0	Silica .....	4.5
Iron .....	4.0	Manganese .....	0.6
Copper .....	1.8	Lime .....	0.3
Lead .....	1.3	Sulphur .....	17.5

The three following methods were used in the leaching and purification of the zinc-sulphate content of the flue-dust. The first two methods were tried on a small experimental scale only, and the third on a commercial scale.

**FIRST METHOD.** Take 95% by weight of flue-dust and 5% of roasted ore from the furnace; add an equal amount of water by weight, and boil for two hours. The following reactions take place:

The ZnO must be slightly in excess to give the above reactions. As the lead, silica, and traces of silver are already in an insoluble form, upon filtration of the above liquor there results a solution of zinc sulphate, with traces of sodium salts derived from the original flue-dust, and also a small amount of manganese sul-

phate and aluminum sulphate. During the concentration of this liquor, preliminary to crystallization, the traces of sodium salts are thrown down in the form of scale on the heating coils.

**SECOND METHOD.** Roast the flue-dust at a dull-red heat until the following reactions are complete:

The roasted dust is cooled and then treated with an equal weight of water, heated for one hour, and filtered. This gives approximately the same quality of liquor as the first method.

**THIRD METHOD.** The flue-dust is placed in a lead-lined dissolving tank with twice its weight of water, kept hot with a lead-pipe steam-coil, and agitated with a mechanical stirrer for 8 to 10 hours. Then add sufficient soda ash to give the mixture a basic reaction, thereby precipitating the iron and manganese and neutralizing any free acid that is present. Next treat the mixture with chlorite of lime to oxidize the balance of the iron and manganese, and add more soda ash to precipitate these. Sodium sulphide is then added to precipitate any traces of copper not removed by the soda ash. Zinc-dust may be used to remove the last traces of copper, but it has a tendency to reduce some of the iron and drive it back into solution. The mixture is then filter-pressed, using a press built of wood as far as practicable, with lead-pipe connections.

Concentrate the liquor in a lead-lined tank with a lead-pipe steam-coil until it registers 52° or 53° Baumé. Then crystallize in lead-lined tanks.

Dry the crystals for 20 minutes in a centrifugal machine with a brass or copper basket. This method gives a crystal pure enough for the lithopone manufacturers.

The residue from the filter-press contains all the silver, gold, copper, and lead, and is in a form acceptable by the refineries for the recovery of these metals. The manufacturing cost of producing zinc sulphate from flue-dust, making no charge for the flue-dust, but including maintenance of plant and all other items, is from \$20 to \$25 per ton.

KALGOORLIE, in Western Australia, began its career as a gold-mining district when Pat Hannan found gold-bearing cement in the desert country 25 miles east of Coolgardie on June 14, 1893. The deposit was the sort of concentration made by wind and rain in an arid region. The gold was extracted by dry-blowing. In the course of this superficial mining a quartz vein was struck in the bedrock, and it served as the basis for a wild-cat flotation called the Great Boulder Proprietary. While working on the low-grade quartz vein the shallow workings broke into a rich lode, the top of which, being soft, had been eroded and covered by detritus. This proved the vein that made the Great Boulder one of the great gold mines of the world. To the end of 1915 it had produced \$49,092,333, and distributed \$25,000,000 in dividends, but it began life as a puling wild-cat.

## The Manganese Deposits of Philipsburg, Montana

The shortage of manganese brought about by the effect of the War on oceanic transportation and the derangement of the foreign manganese industry have stimulated production in many parts of the United States. Philipsburg, unknown a few years ago as a commercial source of manganese, has taken first rank as a domestic source of ore suitable for making ferro-manganese. For the few months prior to an examination by Joseph B. Umpleby of the U. S. Geological Survey in August of this year, the daily production was about 500 tons and this output will probably be maintained for several months. We are indebted to Mr. Umpleby for the information that follows.

All of the manganese mines are situated in the foothill area east of the town of Philipsburg, and at no point more than  $2\frac{1}{2}$  miles from it. The deposits are scattered irregularly over an area about  $1\frac{1}{2}$  miles north and south by about 1 mile east and west. Wagon-roads from 1 to 2 miles long lead from the mines to the Northern Pacific railroad. In August 1917, shipments were being made from 14 deposits, and several others were being tested.

The manganese deposits are enclosed in magnesian limestone and fall into four general classes, which grade into one another: (1) Concentrations of manganese oxides on the hanging-wall side of silver-bearing quartz veins; (2) replacements of certain beds of limestone where crossed by fissure-zones; (3) irregular replacements adjacent to the grano-diorite contact; and (4) replacements of certain beds up to 1000 ft. from the igneous contact, where fissures have not been recognized.

Deposits of the several groups seem to run about the same in manganese, but the representatives of the third group contain a greater amount of waste, and the only member of the fourth class is high in silica. In preparing the ores for shipment, waste is picked out by hand and the entire product passed over screens to reduce the silica content. The screening from one of the larger mines runs 32 to 40% manganese and 20 to 28% silica, whereas the lump ore averages 40.5% manganese and 15% silica. Most of the ore shipped from the district runs about 45% manganese, less than  $2\frac{1}{4}$ % iron, and about 15% silica, with low phosphorus. Material of this grade is worth about \$30 per ton f.o.b. Philipsburg.

An effort will be made to concentrate the screening and the ore from several silicious deposits known to be of considerable size. To this end the Philipsburg Mining Co. is now building a concentrator, and several other operators are investigating the problem. Experiments show that it is possible to make a highly desirable concentrate, but that loss in the tailing is heavy.

In a locality like Philipsburg, where extraction follows development closely, it is exceedingly difficult to form an idea of the tonnage of ore available. Some of the larger orebodies will probably yield from 10,000 to

40,000 tons each, and it is possible that a few of them may greatly exceed this estimate. It also is likely that a number of the small prospects will add considerably to the total production of the district. In view of the present meagre development, however, it seems most reasonable to estimate that the Philipsburg deposits contain 135,000 tons of ore suitable for making ferro-manganese, and that the amount may be 350,000 to 400,000 tons. Under prevailing market conditions this ore should be recoverable. The manganese carbonate, rhodochrosite, appears on the dumps of some of the old silver mines, but as the workings are now inaccessible and no data are available concerning the quantity of such material, it is not included in the estimate. An incomplete analysis of a typical piece of the rhodochrosite follows: Mn 41.39, Fe 0.22,  $\text{SiO}_2$  0.24%. Such material is highly desirable and it is possible that considerable deposits of it may be found below the oxidized ore.

It is expected that a more complete report will be issued by the U. S. Geological Survey on this subject within the next few months. Several geologists of the Survey familiar with metalliferous deposits have been making systematic examinations of manganese and manganese ore-bearing localities during this season with a view to appraising the available resources in manganese and to aid where possible the mining industry in extending exploration for these ores and thus further stimulate production.

## Effect of Sulphides on Cement

Cement is materially affected by the presence of sulphides, whether in the original material or in the water employed for mixing. J. C. Witt has conducted elaborate experiments on this subject under the auspices of the Bureau of Science at Manila, Philippine Islands. His conclusions, printed in the Philippine Journal of Science (Vol. 9, sec. A, No. 6) are that, (1) The setting time of cement is greatly modified by the presence of sodium sulphide. With low concentrations the set is retarded, but, after reaching a maximum, further additions accelerate the set. In general, the cements highest in iron content are most sensitive to this influence; (2) there is a decided decrease in tensile strength. The percentage-loss varies with the concentration of the sulphide and with the iron content of the cement. The briquettes appear normal in every other respect, except in color. There is no cracking nor distortion of any sort; (3) in most cases sulphide may be present in concentrations up to 1 gramme per litre without causing the tensile strength to fall below the U. S. Government specifications; (4) certain results indicate that a colloid is formed by the action of sodium sulphide on the iron in the cement; (5) based on the results of both chemical and physical observations, the following explanations of the decrease in tensile strength are offered: (a) The precipitated colloid forms films of inert material through the cement and interferes with the cohesion; (b) When

the colloid is precipitated a portion of the dissolved calcium hydroxide is removed from solution. Since the latter substance is a very important factor in the strength of cement, the strength will be lowered when some of it is removed; (6) It is probable that other factors influence the effect of sulphide on cement. Among these are the fineness of the cement, the temperature at which it is mixed, the proportion of water used, and the amount of dissolved calcium hydroxide.

## Manganese Investigations

On account of the increasing difficulty of obtaining imported manganese and the vital importance of the metal in the production of the steel, the U. S. Bureau of Mines is making an investigation of the possibilities of relief through a more extensive use of domestic ores. Since the steel-industry is dependent on manganese and because the problems of manganese-ore concentration are similar to those in the case of iron ore, these investigations have been assigned to the Lake Superior station, recently established at Minneapolis.

The Lake Superior region is an important producer of manganiferous iron ores; it contains large reserves of these ores, and can mine and ship much larger amounts if metallurgical practice can be so modified as to create a better demand for them. For many years steel-makers have relied on manganese alloys imported from England, and on manganese ores from India, Russia, and Brazil. These ores are high in manganese and are suitable for making 80% ferro-alloy, which has been demanded in constantly increasing quantities in proportion to the growth of the open-hearth process. With the low ocean freight-rates that prevailed during the past 10 or 20 years, it was well nigh impossible for producers of domestic manganese ore to compete with imported ore. Consequently the manganese industry of the United States languished. There was little incentive for exploration and development and mining was carried on without system. With the outbreak of the War in Europe in 1914 the manganese industry faced new conditions. The entrance of Turkey into the conflict shut off shipments of Russian ore from the Caucasus. A growing scarcity of shipping made it increasingly difficult to transport the material from the usual sources of supply and the great rise in ocean freight-rates increased the cost at the very time when the producers in the United States faced an unprecedented demand. Until last year this demand had little effect on production because of the difficulty of interesting capital in an industry that might die with the ending of the War. A clearer and broader conception of the causes of high manganese-prices and a belief in the likelihood of these causes existing for some time after the War has partly removed that fear. A still greater difficulty in obtaining domestic supplies is the fact that manganese-ore of high grade, suitable for making 80% 'ferro,' is scarce in the United States, while manganiferous iron ores are much more abundant. These have not been in much de-

mand by the steel-industry in the past and it is essential to investigate by research on a large scale the possibilities and limitations involved in their use. It is this work that the Bureau of Mines desires to undertake, and the sooner the facts can be determined the more valuable they will be. Suggestions and constructive criticism will be greatly appreciated.

The Bureau plans to assemble and tabulate as much information as possible concerning the character and available tonnage of known domestic ore, the current practice in mining and concentration, and the present methods of manufacturing manganese-alloys and of using them in steel. When compiled, this material should afford a starting point for original researches dealing with related problems.

The possibility of concentrating various types of manganese ores will be studied; fundamental thermo-chemical data relating to manganese and its compounds will be determined, and the equilibria of the fundamental reactions between iron and manganese compounds will be investigated. Also, attention will be given to the development of substitutes for manganese in steel-making, to the possibility of using alloys that are not employed in what is now considered standard practice, such as alloys containing between 20 to 80% manganese, and those containing manganese with other constituents, as well as the possibility of increasing the manganese-content of basic pig-iron in order to lessen the amount of the alloy added at the end of a heat. Part of this would be left as residual manganese in the bath-metal. Another problem will be the production of manganese-alloys in the electric furnace where power is cheap. The Bureau has been conducting a series of experiments at Pittsburgh on the production of alloys in the electric furnace from slags high in manganese. In the laboratories of the Lake Superior station, which co-operates with the University of Minnesota, concentration tests of ores will be made. Similar investigations in other alloys will be undertaken at laboratories throughout the country.

THE TECHNICAL commission of Colombia has recently concluded its studies for the completion of the Cauca Valley railroad from kilometre 63 south of the city of Cali to Popayán, a distance of 86 kilometres. The maximum grade will be 2.3%, and the minimum radius of curvature will be 80 metres. The estimated cost is \$3,412,000. The construction of this road will open to development a territory rich in gold placers and in mines of silver. Popayán was a famous mining centre in the early days, and great fortunes were made. The remoteness of the region has retarded development of the mines by modern methods. The climate is salubrious, in this respect differing radically from miasmatic valleys in the lower Cauca. The railroad will open easy communication from the port of Buenaventura on the Pacific coast.

ALUMINUM sulphate is now quoted at 3½ to 4¼c. per pound.

## Effect of Mouthpieces on Flow of Water

An elaborate series of tests was recently made by Fred B. Seely on the effect of mouthpieces on the flow of water through a submerged short pipe. These experiments were made with the advantage of the excellent hydraulic equipment of the Engineering Experiment Station of the University of Illinois, and the results have been issued as Bulletin No. 96 from the Station. The data are given in detail, and are reduced to mathematical expression, accompanied by tables and curves. The conclusions reached are the following:

The preceding discussion has shown that the losses accompanying the flow of water depend largely upon the state of its motion, and this in turn is influenced by many factors, the effects of which often can be but roughly estimated. While the results of the experiments tend to define the range of such effects for certain conditions of flow, additional experiments would be necessary to establish all the inferences that have been suggested. The conclusions here given, however, seem justified:

(a) As applying to conditions likely to be met in engineering practice, the value for the head lost at the entrance to an inward-projecting pipe, that is, without entrance mouthpiece and not flush with the wall of the reservoir, is 0.62 of the velocity-head in the pipe ( $0.62 \frac{v^2}{2g}$ ) instead of  $0.93 \frac{v^2}{2g}$ , as usually assumed. To put it in another form, the coefficient of discharge for a submerged short pipe with an inward-projecting entrance is 0.785 instead of 0.72 as given in nearly all books on hydraulics. Further, the lost head at the entrance to a pipe having a flush or square entrance is 0.56 of the velocity-head in the pipe ( $0.56 \frac{v^2}{2g}$ ) instead of  $0.49 \frac{v^2}{2g}$  as usually assumed. In other words, the coefficient of discharge for a submerged short pipe with a flush entrance is 0.80 instead of 0.82 as given by nearly all authorities.

(b) The loss of head resulting from the flow of water through a submerged short pipe when a conical mouthpiece is attached to the entrance end, may be as low as 0.165 of the velocity-head in the pipe ( $0.165 \frac{v^2}{2g}$ ) if the mouthpiece has a total angle of convergence between  $30^\circ$  and  $60^\circ$  and an area of ratio of end-sections between 1 to 2 and 1 to 4, or somewhat greater. In other words, the coefficient of discharge for a submerged short pipe with an entrance mouthpiece, as specified above, is 0.915.

(c) The loss of head which occurs when water flows through a submerged short pipe having an entrance mouthpiece varies but little with the angle of the mouthpiece if the total angle of convergence is between  $20^\circ$  and  $90^\circ$ , and if the area-ratio is between 1 to 2 and 1 to 4, or somewhat more. The loss of head for any mouthpiece within this range would be approximately 0.20 of the velocity-head in the pipe ( $0.20 \frac{v^2}{2g}$ ). There is, therefore,

little advantage to be gained by making an entrance mouthpiece longer than that corresponding to an area-ratio of 1 to 2. Thus, an entrance mouthpiece, with a total angle of convergence of  $90^\circ$  and the length of which is only 0.2 of the diameter of the pipe, gives approximately  $0.20 \frac{v^2}{2g}$  for the loss of head.

(d) The amount of velocity-head recovered by a conical mouthpiece when attached to the discharge end of a submerged short pipe depends largely upon the angle of divergence of the mouthpiece, but comparatively little upon the length of the mouthpiece. This is true for lengths greater than that corresponding to an area-ratio of 1 to 2 and for total angles of divergence of  $10^\circ$  or more. The amount of velocity-head recovered decreases rather rapidly as the angle of divergence increases from a total angle of  $10^\circ$  to  $40^\circ$ . At or near  $40^\circ$  the amount of velocity-head recovered rather abruptly falls to approximately zero.

(e) A conical discharge mouthpiece, having a total angle of divergence of  $10^\circ$ , and an area-ratio of 1 to 2, when attached to a submerged short pipe, will recover 0.435 of the velocity-head in the pipe, which is 58% of the theoretical amount of recovery possible.

(f) The amount of velocity-head recovered by a diverging or discharge-mouthpiece, when attached to a submerged short pipe, is considerably more when a converging or entrance-mouthpiece is also attached than it is when the entrance end of the short pipe is simply inward-projecting, that is, with no mouthpiece attached. This excess in the velocity-head recovered diminishes rather rapidly as the angle of the discharge-mouthpiece increases, and it becomes zero for a discharge-mouthpiece having a total angle of divergence of approximately  $40^\circ$ . This increase in the velocity-head recovered is probably due to the effect of smooth flow in the pipe as the water approaches the discharge-mouthpiece. The smooth flow allows the mouthpiece to recover more of the velocity-head in the pipe than when a more turbulent flow exists; this increase amounts to as much as 33% in the case of the discharge-mouthpiece having a total angle of divergence of  $10^\circ$  and an area-ratio of 1 to 2.

While these conclusions are drawn from experiments on the flow of water through a particular short pipe having various entrance and discharge conditions, it is felt that the results of the experiments are applicable in a general way to a large variety of cases in engineering practice where the contraction and expansion of a stream of water occurs.

The deductions made are capable of use in connection with the loss of head which occurs when a stream contracts or expands under differing conditions of flow and they show the marked effect that turbulence of flow may have upon the amount of head lost, and they also have a direct bearing upon problems in hydraulic practice that involve the contraction and expansion of a stream in flowing through passages. Comparatively little experimental work has been done hitherto to determine the value of conical mouthpieces of various angles and

lengths in reducing the lost head at the entrance to and discharge from a submerged pipe, particularly for mouthpieces of the sizes and proportions comparable with those met in engineering practice. The need for such experiments was apparent. The minimizing of the lost head due to the contraction and expansion of a stream may be of considerable importance in many hydraulic problems; for example, the intake of a pipe, particularly when the pipe is of short length and of large diameter, the suction and discharge-pipes of a low-head pump, the reduction or expansion from one pipe to another of different diameter or of different shape, the passages through a large valve, the passages through locomotive water-columns, the draft-tube to a turbine, the connection from a centrifugal pump to a main, the sluice-ways through dams, the slat-screens at head-gates, culverts, and short tunnels, jet-pumps, the Boyden diffuser as formerly used for the outward-flow turbine, the Venturi meter, the suction and discharge pipes of dredges, and the guide vanes and runner of a turbine. Losses due to this cause are difficult to estimate and easy to overlook. Even where such losses are in themselves of little consequence as compared with other quantities involved, they may have an important influence upon subsequent losses on account of the turbulent motion started by the contraction or expansion. The efficiency of a drainage-pump or other low-head pump, for example, may be increased by an entrance-mouthpiece on the suction-pipe because it allows the pump to receive the water in a smoother condition of flow. It is well known that a turbine must receive the water from the guide-vanes without shock if, in the subsequent flow through the runner, the energy of the water is to be absorbed efficiently by the turbine. The loss of head through a Venturi meter may be considerably increased if the meter is placed too short a distance downstream from a valve, elbow, or other obstruction or cause of disturbance in the pipe. The friction-factor for a pipe following an obstruction or bend may be changed by the disturbance thus caused; the lost head at the entrance to a pipe, particularly when projecting inward, may be more than that ordinarily assumed for a tube three diameters long. There is but little definite knowledge on the subject of the effect of abnormal conditions, and it offers a large scope for investigation. The fact that a comparatively small change in the form of the blades of a turbine-runner may result in a large effect on the efficiency of the turbine should prove suggestive when estimating the probable effect of turbulent flow in less severe or critical cases. It is also worth mentioning in this connection that the recent advances in turbine design have been due largely to the attention given to the approach-channels to the guide-vanes and to the design of the draft-tube.

The flow of water usual in engineering practice is rather turbulent. The general equation of energy, or Bernoulli's theorem, so generally used in hydraulics, applies only when the particles of water move with uniform velocity in parallel stream-lines. Although this condition of flow seldom occurs, satisfactory analyses

may often be made by using an average velocity and introducing empirical constants. A very slight change in the conditions under which flow takes place may cause a large difference in the behavior of the water. There is always danger in extending the use of experimental data or empirical constants to apply to conditions of flow different from those under which the data were obtained.

## A Regiment of Miners

The following letter is being sent to mine-managers:

War Department,  
Office of the Chief of Engineers,  
Washington.

Subject: Recruits for Mining Regiment.

1. The Engineer Corps of the United States Army has recently been authorized to raise a regiment of Miners for service in France. We inclose herewith a brief description of the service, the character of men wanted and blank applications for enlistment.

2. Your name has been given us among others as one who is an employer of miners and who would be willing to help us in securing the men wanted. There are, no doubt, in your district, some men who sooner or later are going to enlist for the war and to whom this Mining Service may appeal. We ask that you aid us by sending these men to us now.

3. We appreciate that we are asking you to make a sacrifice in sending men to us at this time, but the total number of men wanted is not large, some 1500 in all, and if each Mine Manager or Superintendent will send us a few men, the desired quota will soon be raised. Information recently received from General Pershing indicates that these men are urgently needed.

4. We request that you distribute the inclosed information and enlistment blanks to such men as you are able to reach who are eligible and likely to be interested. In addition, we would like to have the names and present addresses of skilled men who have already been drafted from your district.

5. We wish to thank you in advance for your co-operation.

By order of the Chief of Engineers:

O. B. PERRY,  
Major, Engineer Officers' Reserve Corps.

Address reply to

The Commanding Officer, 27th Engineers,  
Office of the Chief of Engineers,  
War Department, Washington, D. C.

DE-OXIDIZING of steel by the use of carbohydrates is being tried as a means of economizing manganese. Desulphurization is also said to result, and only traces of carbon are added to the steel. The substances used are sugar, starch, and cellulose. The purer the carbohydrate the better the result obtained. It is said that wood-shavings serve the same purpose.

## War-Tax on Canadian Mines

Taxation of mining companies in Canada under business-profits war-tax or income-tax is of such conservative character as to have received almost unanimous endorsement by mining-company executives. Not only do Canada's war-taxation measures leave profits untouched up to 7%, but so generous is the allowance for exhaustion of mines that not more than 20 companies, probably fewer, will pay any Federal war-tax in 1917. This bears out the contention of the Minister of Finance that Canadian mining corporations have more freedom to divide earnings than similar corporations in most other countries. Out of the great annual dividend totals from the Cobalt and Porcupine districts the Ontario government gets just \$300,000, and the whole mining revenues of the British Columbia government in a year are not above \$150,000. The Federal finance department reckons on a revenue from mining sources under war-taxation of only a few millions. It is not possible to set forth the profits of various Canadian mining companies and calculate on the amount of their 1917 levies. The Finance department has no standard practice. While the United States government stipulates that not more than 5% of the gross output in any one year shall be allowed for exhaustion of property, the Canadian authorities have left themselves free to place that percentage anywhere between 2 and 15. In the opinion of the Finance Minister the United States standard is too low for many metalliferous mines that may have an average life of only 8 to 10 years. Some Canadian coal-mining companies are not being allowed even a 5% rate for depreciation of property. With some silver and copper mines enjoying depreciation allowances of 10 to 15% of gross output, it is plain that the total of Canadian mining companies liable to payment of war-tax will not come above 20. In 1915, exclusive of nickel companies, only 24 mining companies in the Dominion paid dividends.

The following statement of Sir Thomas White, minister of finance, may smooth out some misunderstandings as to method of calculating mining companies' capital for taxation purposes. Seven per cent on 'capital' is free; what that 'capital' is has been expressed by the Minister thus:

"For the sake of taxation, you have your capital, your reserve or rest account, and your accumulated profits, substantially representing net capital of company invested in the business. But in case of mining companies you will find many anomalies such as a company incorporated originally with \$250,000 capital. Property today may be worth \$5,000,000. A holding company has been created holding stock in original company and dividends of 15% or 20% are being paid on \$5,000,000. Taxation applies to underlying company, but regard is had to amount of fully paid-up capital, values of reserves, rest, and accumulated property—the three put together representing value of the mine. Again, where a company bought a property at \$100,000, and spent

\$150,000 in plant, a discovery of rich ore ran valuation of the mine to a million dollars. In opinion of the department the capital is \$250,000. Reserve, rest, and accumulated profits make up the balance. Capital of that mine for purposes of taxation is taken at \$1,000,000."

In 1915 no war-tax was collected, but as the initial Canadian measure of war-taxation, called the Special War Revenue Act, was retroactive, companies earning above 7% on capital were obliged to pay 25% of surplus profits on two years' operations. These deductions were usually charged against first accounting period in 1916, but exact amounts paid are by no means ascertainable in case of all mining companies' balance-sheets, war-tax being included with other extraordinary items. The business war-tax of 1916, and its amendments, greatly increased the load of taxation by taking 50% of profits between 15% and 20%, and 75% of profits above 20%. Latter tax applies only to accounting periods falling within 1917. It must be emphasized that the business-profits war-tax does not supersede original special war-revenue tax taking 25% of profits in excess of 7%. Both measures work in harmony.

ALUMINUM cables reinforced with steel have come into use lately for long-span high-voltage electric transmission-lines. The co-efficient of expansion of aluminum is about one-third greater than that of copper, so that, in a climate where the extremes of temperatures are considerable, it is necessary to provide for the expansion and contraction of an aluminum cable by giving it a greater sag between supports than would be necessary with a copper cable. This was feasible in the days of short spans and low voltages, but now that the reverse condition commonly exists it has been found necessary to reinforce aluminum cables with a steel-strand; the steel to provide the strength and the aluminum the electrical conductivity. Thus in a seven-strand cable the centre strand is of steel, heavily galvanized to protect it from atmospheric corrosion, and the six outer strands are of aluminum. Such cables can be made with any number of strands, the ratio of steel to aluminum being arranged to fit the particular need for which the cable is required. Steel reinforced cables are being used in a number of transmission-lines on this continent.

PLACER MINING in the Kantishna district, Alaska, is done by the open-cut method. The upper part of the gravel is sluiced off within a foot or two of bedrock, then shoveling the gravel into the sluice-boxes by hand. Most of the miners complete the ground-sluicing early in the spring when the water is abundant, but a few have built automatic dams, and are thus enabled, by alternately storing and releasing the water, to carry on the operation during the period of low-water.

WOLFRAM exports from Tavoy, Burma, according to reports from Rangoon, amounted to 202 long tons in June, compared with 104 tons for the same month in 1916.

## Safety-Orders for Explosives

We reproduce recent orders issued by the California Accident Commission relative to the storage and use of explosives, this being known as order No. 1105. These rules for the use of blasting materials have a highly economic importance aside from their desirability in the prevention of accident. Much loss of time and efficiency in mining results from disregard of the simple precautions set forth in this circular. It is always agreeable to the public when a 'safety first' requirement is found also to have the desirable effect of increasing revenue.

(1) Magazines shall not contain tools other than a wooden mallet and wedge or a phosphor-bronze chisel.<sup>1</sup>

(2) When supplies of explosives or fuse are removed from a magazine, those that have been longest in the magazine shall be taken first. Packages of explosives shall be removed to a safe distance from the magazine before being opened, and such package shall be opened only with wooden or bronze tools. Empty or broken boxes, paper, and rubbish shall not be allowed to accumulate within 100 ft. of a magazine. Such boxes, paper, and rubbish shall be removed to a safe distance (at least 500 ft.) and burned or otherwise disposed of.

(3) Packages containing explosives shall not be opened in a magazine.

(4) Magazines shall at all times be kept clean and dry. Before repairing or altering a magazine, explosives shall be carefully removed and the magazine cleaned thoroughly. Nails or screws must not protrude from any part of the interior of a magazine.

(5) No detonators shall be taken into a magazine containing other explosives.

(6) No detonators shall be transported in the same receptacle with other explosives.

(7) Detonators shall not be removed from original container except as they are used for capping fuses.

(8) Explosives shall not be thawed in a magazine where other explosives are kept.

(9) Explosives shall not be thawed in any device other than a room, box, or other receptacle heated by exhaust steam, hot water, manure, or electricity. If steam or water be the agent employed, the stove, boiler, or other primary source of heat shall not be nearer to the thawing-room than 10 ft. Explosives shall not be thawed by direct contact with steam. If electric current be the thawing agent, the current shall not be brought within 5 ft. of the explosive to be thawed, and in no case shall explosives while being thawed be exposed to a temperature higher than 80° Fahrenheit.

(10) Explosives shall not be placed or left within 5 ft. of live electric wires.

(11) Explosives shall not be kept exposed to the sun any longer than is necessary. Explosives deteriorate under the direct heat of the sun.

(12) No person shall remove explosives from a maga-

<sup>1</sup>At the San Francisco meeting, the omission of the clause following the word 'tools' was suggested.

zine without the written or verbal orders of the superintendent or foreman of the job.

(13) Fire-extinguishers or hydrants and hose shall be provided and kept ready near all powder-magazines for use in case of fire outside the magazine.

(14) Smoking in a powder-magazine or while handling powder, or entering a magazine with an open light is prohibited.

Order 1106: Fuse.

(1) No fuse shall be used for blasting that burns faster than 1 ft. in 30 sec. or slower than 1 ft. in 55 sec. Only fuse of sufficient length shall be used so as to allow the men to retire to a point of safety before firing a hole or round of holes.

Under no circumstances shall fuse less than 2½ ft. long be used.

(2) Caps and electric fuses are extremely sensitive, hence it is forbidden to carry them in one's pocket or store them in buildings except a magazine as specified in these Orders.

(3) The use of oil or grease to waterproof joints between cap and fuse is forbidden. This practice causes misfires. The use of a compound sold by powder manufacturers for waterproofing, such as roofing paint, celakap, etc., is recommended.

(4) In capping fuse, at least 1 in. shall be cut from the end of each coil of fuse to be used in blasting. (This will prevent damp fuse-ends from getting into the cap.)<sup>2</sup>

(5) Only a crimper<sup>3</sup> shall be used for attaching fuse to blasting cap. Crimping with the teeth or a knife is strictly forbidden. Crimpers shall be provided and kept in good repair ready for use.

(6) It is forbidden to use fuse that has been hammered or injured by falling rocks or from any other cause. (Such injury may increase the rate of burning, or may render the fuse entirely useless.)

(7) In cold weather, fuse shall be warmed slightly before uncoiling, to avoid cracking the fuse.

(8) The hanging of fuse on nails or other projections, which cause a sharp bend to be formed in the fuse, is prohibited.

HARDWOODS, such as oak, beech, birch, hickory, ash, and locust have a comparatively high fuel-value, and one cord of the dry wood is equivalent to a ton of bituminous coal. Pine, hemlock, douglas fir, sycamore, and soft maple require two cords to equal a ton of coal. The fuel-value is related to the weight, 4000 lb. of wood yielding as much heat as one ton of coal. Resinous woods, however, are better than those which do not contain that substance.

THE gold reserve of the United States is approximately \$3,000,000,000. Before the War it was about \$1,900,000,000. The significance of the increase in our gold reserve lies in the fact that there are, in round figures, only eight and a half billions of coined gold and gold bullion in the world. The world's credit-structure rests upon that foundation.—'Amer. Met. Market.'

# REVIEW OF MINING

## LEADVILLE, COLORADO

NEW STRIKE AT FANNY RAWLINGS.—MANGANESE ORE.

At the Fanny Rawlings property on Breece hill a rich shoot of silver ore has just been cut by development carried on by Ray McConihay, who recently succeeded Robert W. Coates as manager. The shoot occurs in a big fissure-vein which traverses the entire property, running almost due north and south. The ore has been opened from three levels—the second, intermediate, and third. The second and third levels are being developed by winzes on the vein, while in the intermediate work is being done by raising. A force of men has been put to work on the first level also, and indications are that the shoot will be found there. The ore is a good silver-bearing sulphide. A high-grade streak in the vein assays 0.51 oz. gold, 330 oz. silver, and 6% lead. The main shoot assays 80 oz. silver. Mr. McConihay has shipped a four-ton lot of the high-grade ore, which was hauled from the property to the smelter, but he has been unable to ship any of the lower-grade material because the Denver & Rio Grande has not yet completed the standard-gauge siding to the property which extends from the main-line on Breece hill. Work on the siding is now in progress and will be finished this week. The surface bins, with a capacity of 100 tons, have been filled with ore and the underground chutes are now being used to store the material. Mr. McConihay estimates that he will be able to maintain a steady output of 50 tons per day, and in addition will ship regular lots of sacked high-grade ore. The discovery was made while developing two large bodies of zinc sulphide lying on either side of the fissure. The vein is a continuation of one of the big fissures that has produced rich gold ore.

The strike at the Fanny is regarded as an event of great importance by mining men operating in the Breece Hill district. It is the first evidence of the existence of high-grade silver ore in this part of the district, and opens new possibilities for development in many of the old properties including the Ibox. Ore assaying as high as 100 oz. silver has been found in the Ibox, but not in large bodies.—M. J. Nicholson, superintendent for the Western Mining Co., has secured a lease on the Big Four property, adjoining the Fanny Rawlings, and has started a small force of men to work cleaning out old drifts and putting the mine in shape for operation. New surface machinery will be erected this week. Prospecting for the extension of the new Fanny vein will be first undertaken.—A company of Leadville men, composed of T. V. Gallagher, James T. McMahon, H. M. Shephard, F. H. Sinclair, and T. J. Morrissey, leasing on the Nisi Prius Extension in Iowa gulch, has resumed operations and is shipping 50 tons of manganese daily. The ore is being marketed through Gustavus Sessinghaus who has been active in the district recently investigating deposits of manganese and pyrite. The orebody at the Nisi Prius is now 100 ft. long, 65 ft. wide, and 35 ft. high. The limits of the shoot have not been reached at any point. The ore contains 33% manganese.—Lessees at the Bohen shaft on Carbonate hill, where an immense body of manganese has been opened, have made another discovery that greatly increases the dimensions of the deposit. In a new drift, driven from the shaft 25 ft. below the level on which the ore is now being developed, the same shoot has been cut. The ore at this

point contains less manganese but considerably more silver.

This week has witnessed the arrival of greatly improved conditions regarding the car shortage. At the Breece Hill properties in particular, have the operators been able to ship more regularly and move a heavier tonnage than for some time. Box-cars, coal cars, gondolas, and every other class of rolling stock that can be secured is being put into service here.

Production from the Penn properties on Breece hill has been stopped until the Denver & Rio Grande completes remodeling the siding from narrow to standard gauge. This work has been under way for several weeks and will be finished by the middle of the month. The Penn combination produces a large output of iron and gold ore.

## TORONTO, ONTARIO

INTERNATIONAL NICKEL.—HOLLINGER.—MCINTYRE.—KIRKLAND LAKE.

The Canadian Copper Co., the subsidiary of the International Nickel Co., has paid into the treasury of the Province of Ontario, a check for \$1,366,892, for taxes for the last two com-

THE M'KINLEY-DARRAGH MINE

pleted years of the company's operations under the retroactive taxation bill adopted at the last session of the Legislature. The tax, while levied on the Canadian Copper Co., is computed from the earnings of the International Nickel Co. and based on the value of the nickel matte exported from Sudbury for refining, which is determined by deducting from the finished production the cost of refining and marketing. The present tax is 5% of the profits up to \$5,000,000, with an addition of 1% for each additional \$5,000,000 of profits, should they ever reach such a figure.

The new milling equipment of the Hollinger Consolidated has been completed after considerable delay caused by adverse conditions, especially the lack of efficient labor. It is now being tried out, and is expected to increase the present milling capacity of 1800 tons by approximately 1000 tons. There is little prospect, however, of its being operated to anything approaching capacity for some time, as further interferences with the inadequate labor-supply are inevitable, owing to the conscription measure now in process of enforcement. The expenditure in connection with the new equipment, including the extra power and the equipping of the new central shaft, is estimated at about \$1,000,000.—The financial statement of the

Dome Mines for the six months ended September 30, shows a gross income of \$701,810; operating and developing costs \$534,575; and net profits \$167,234, which, added to the surplus of March 31, makes a total of \$864,285. Deductions of \$141,164 for depreciation, \$27,415 for war tax, and \$100,000 for dividends, leave a surplus of \$595,706. While these figures do not indicate that present operations are yielding a profit, it is realized that the conditions responsible for the decreased output are merely temporary, as development has largely increased the ore-reserve and under normal conditions production will be greatly increased. The main working shaft will be sunk shortly to the 1500-ft. level.—The Schumacher is treating 180 tons of ore per day, the mill-heads being nearly \$7 per ton. Operating costs being maintained at about \$4 per ton, substantial profits are being realized.—The McIntyre mill is running to capacity and treating about 500 tons per day of ore running \$7 per ton or more. The Jupiter shaft is being sunk to the 1000-ft. level. The big vein is believed to cross the whole of the Jupiter property, and to enter the Plenaurum adjoining, on which the McIntyre holds an option.—The Coniagas, of Cobalt, which recently acquired the Anchorite, has let a contract for the sinking of a 3-compartment shaft to the depth of 500 ft.—The Newray has been taken over on option by the Crown Reserve and Dominion Reduction companies. This property, formerly known as the Rea, comprises 320 acres and was at one time regarded as a very promising mine, as it has paid dividends to the amount of \$120,000 in 1914. The main vein faulted and has not since been re-found, but other veins of potential value have been discovered.

An important development in the Kirkland Lake camp is the cutting of a high-grade orebody, 12 ft. wide, on the 325-ft. level of the Elliott-Kirkland, which indicates a considerable extension westward of the auriferous zone. It is of special importance to the Kirkland Lake mine as evidencing mineralization of the entire width of that property. The Burnside, adjoining the Tough-Oakes, has been taken over by the Aladdin-Cobalt. A number of veins on the property have been opened up. A depth of 600 ft. has been reached in the winze put down from the 400-ft. level of the Teck-Hughes. A station is being cut and a cross-cut will be run to connect with the workings from the main shaft.

An approximate estimate of the production of silver from the Cobalt mines for the 10 months ended October gives a total of 17,000,000 oz. of a value exceeding that of the total output of 1916.—The new mill of the McKinley-Darragh is practically completed. It will have a capacity of 500 tons per day, 250 of which will be tailing, there being quite a large accumulation that can be profitably treated by flotation. The ore-reserves have lately been increased by the cutting of several new veins on the 450-ft. level.—The Buffalo flotation-mill is treating old tailing at the rate of about 400 tons per day.—The annual report of the Temiskaming & Hudson Bay for the year ended August 31, shows an income of \$190,992, operating expenses \$96,043, and net profit \$94,949. The ore-reserves are estimated at 107,614 oz.—The Coniagas has passed its dividend due November 1, the directors considering a conservative policy advisable in view of heavy expenditures in the acquisition and development of Porcupine gold claims.

### TONOPAH, NEVADA

TONOPAH MINING CO.—TONOPAH EXTENSION.—JIM BUTLER.—MACNAMARA.

The Tonopah Mining Co. shipped 23 bars of bullion, valued at \$39,300; during the previous week 2563 tons of ore averaging \$12.07 was milled. In the Silver Top 79 ft. of development was done, 103 ft. in the Sandgrass, and 8 ft. in the Mizpah. On the 500-ft. level of the Mizpah the stope on the vertical vein continues in a 2-ft. face of ore. A considerable tonnage from the old dumps is being sent to the mill. Last week the produc-

tion was 2850 tons.—On the 800-ft. level at the Tonopah Belmont, raise No. 16 shows 5 ft. of good ore, while raise No. 17 shows 4½ ft. of medium-grade ore where it cut the faulted segment of the South vein. Between the 800 and 900-ft. levels, the east and west drifts on the Belmont vein, there is a 4-ft. width of medium-grade ore. On the 900-ft. level a cross-cut is being driven to pick up the faulted segment of the Rescue vein. Last week's production was 2415 tons.—The Tonopah Extension Mining Co. during September milled 8692 tons of ore, making a net profit of \$17,866. At the Victor 106 ft. of development was done and 216 ft. in the No. 2 shaft; on the 1440-ft. level, 604 east drift shows a 3-ft. width of ore, while raise 631 has a 5-ft. face of ore; on the 1540-ft. level winze 1501 is going down on ore. The production the last week was 2380 tons.—The West End mill shipped 33 bars of bullion, valued at \$58,193, which represents the final clean-up for October. At the Ohio shaft the ore in drift 530 has increased in value, while drift 531 continues in high-grade ore, proving a large body of ore; on the 555 intermediate, drifts have been started to prove the vein. At the West End shaft raise 677 continues on the vein; drift 717 No. 2 continues to make good progress; raise 623 No. 7 has been started to prove the hanging wall. The output the last week was 913 tons. At the Halifax Tonopah on the 1200-ft. level, cross-cut 1256 has made good progress since it uncovered a vein of low-grade quartz.—At the Jim Butler Tonopah Mining Co. on the 625 intermediate of the Desert Queen shaft, a vein has been cut showing a full face of ore. On the 200-ft. level of the Wandering Boy shaft, the faulted segment of the Wandering Boy vein, recently cut, shows a 4-ft. face of fair ore. The production for the past week was 800 tons.—The MacNamara Mining Co. made its first shipment of bullion since resuming operations. The shipment was valued at about \$10,000, resulting from the treatment of 903 tons of ore. A raise from the 725-ft. level to prove the extension of the Ohio vein, has cut a silicified zone. Development on the 600-ft. level will soon be started. The output the past week was 476 tons.—Last week the Rescue-Eula produced 195 tons, the Montana 105 tons, and the Midway 89 tons, making a total production at Tonopah of 10,223 tons with a gross value of \$178,902.

### COBALT, ONTARIO

CROWN RESERVE.—BUFFALO MINES.—DOME REPORT.—HOLLINGER CON.

During October Cobalt made another record shipment, aggregating 91 cars or 6,360,658 lb., against 4,357,610 lb. for September. The movement among Cobalt companies to secure new silver prospects has become general. The Gowganda field is attracting considerable attention, and already a number of deals has been consummated. Among those interesting themselves in Gowganda are the Mining Corporation and the La Rose.—The Crown Reserve has secured an option on the Newray property at Porcupine. It is proposed to increase the capital of Newray to \$3,000,000. Some 1,800,000 shares will be under option to Crown Reserve at a price said to be 45c. per share. The Crown Reserve agrees to spend at least \$6000 per month in development.—The Mining Corporation of Canada and the Nipissing are now occupying the centre of the stage in Cobalt. The Nipissing is producing upward of \$10,000 per day and the Mining Corporation is exceeding that amount. The aggregate from these two mines for the current year will approximate nearly 10,000,000 oz. of silver.—The Buffalo Mines is in a strong physical condition. A new vein carrying considerable rich ore has been opened recently. The huge pile of old mill tailing is being treated at the rate of about 400 tons per day in the company's oil-flotation plant and a very satisfactory recovery is made. Taking them as a whole, the mines of Cobalt are experiencing a period of exceptional prosperity.

The new milling equipment at the Hollinger Consolidated is completed. This addition will add a capacity for 2800 tons per day to the Hollinger mill and make possible a production of \$9,000,000 annually.—The McIntyre Porcupine is maintaining production at full capacity. Over 500 tons per day is being milled; the mill head ranges from \$7 to \$10 per ton. The physical condition of the McIntyre is satisfactory; the net earnings are large.—The Schumacher is making a far larger profit than at any previous period in its history.—It is officially announced that the Dome Lake ore-reserve approximates over 9000 tons and contains \$82,008. The average grade is \$9.03 per ton.—A contract has been let by the Coniagas company of Cobalt for the sinking of a three-compartment shaft to a depth of 500 ft. on the Anchorite property. The Anchorite is developing well, and is now generally looked upon as an established mine. It is owned by the Coniagas, which has a dividend record of more than \$8,500,000 to its credit.

### HOUGHTON, MICHIGAN

VICTORIA.—MASS CONSOLIDATED.—OSCEOLA CONSOLIDATED.

Omitting the consideration of the higher wages, the highest in the history of the Lake Superior, the important factors that enter into the cost of copper production have advanced at such a startling rate that mining costs during 1917 will be higher here than at any time within 30 years. Coal is costing the average independent producer 90% more than it did last year, when it was higher than it had been for 25 years. Powder is 100% higher and no contracts can be obtained, as the Government has the first call on all output. Steel rails, which are 110% over the prices of a year ago, are hard to obtain. It is difficult to get carbidé even at \$115 per ton and the miners may have to go back to the old-fashioned candle.

The management of the Victoria has decided to continue operations during the winter. The directors visited the property last week. The cost of production during recent months has been above 23¢. However, it is believed that by suspending some construction work now under way, dropping underground development, and confining mining to ore of known merit, the Victoria can continue through the winter at a profit.—Mass Consolidated is shipping 1000 tons of ore per day. The working force is better than it has been for some time, both as to numbers and general efficiency. The physical conditions underground are good.—South Lake is operating only one shift.—In considering the deep cut in the last dividend of Osceola Con. the shareholders must not lose sight of the fact that the future of this corporation depends on the North Kearsarge and on the Old Osceola. The South Kearsarge is gradually becoming more and more a negative proposition. Pillar mining has been going on at both No. 1 and No. 2 shafts, and from these sources a total of 650,000 tons of ore can be secured. Last year over one-third of the South Kearsarge ore came from the foot-wall, cleaning out old stowes and surface stock piles. These sources were not to be drawn upon this year, except the foot-wall workings. Altogether the output of South Kearsarge for 1917 is going to be considerably less than it was last year and the expectations for the year ahead are not good. While the South Kearsarge shafts are gradually getting near their limits it must be remembered that this branch of the mine has for years been the richest of all. Last year the ore showed better than 17 lb. per ton and the year before it exceeded 16 lb. At present the North Kearsarge ore is yielding slightly better than 12 lb. per ton and the Old Osceola rock 12½ lb. per ton. It is difficult to operate these two branches at a profit under existing conditions. The Old Osceola, while it continues to open a good grade of ore in the cross-cuts toward La Salle, is confronted with extremely high mining costs. The long distance that this ore has to be trammed makes it exceptionally difficult.

### SPOKANE, WASHINGTON

STATE METAL-MINING ASSOCIATION.—HECLA DIVIDEND.—  
VALLEY MAGNESITE.

The Washington State Metal Mining Association has been formally organized at Spokane, with George Turner, former U. S. Senator, president; Thaddeus S. Lane, first vice-president; Conrad Wolfe, Frank T. McCollough, Jerome L. Drumheller, George S. Bailey, and R. E. M. Strickland, executive committee. The secretary-treasurer will be elected by the executive board. Purposes of the association the the promotion of the mining interests, the consideration of taxes and industrial insurance, and a closer relation of all persons identified with mining, including the prospector, the miner, the mine-owner, and the investor. The association will encourage the use of safety appliances designed to reduce the number of injuries and the losses in industrial insurance, encourage a diligent search for rare metals and minerals, and aid in building the mining in-

COEUR D'ALENE REGION

terests by giving reliable information. The bureau through which this information is to be disseminated will be operated in conjunction with the bureau of any other State. County divisions will be formed with a vice-president in each county that has mining interests. The State organization will meet annually and the executive committee monthly. The new body will co-operate with the Northwest Mining Association, which is broader in its territorial scope and which has social, educational, and legislative objects.—Enough mineral to maintain a production of 300 tons of crude material per day for 15 years has been proved at the quarries of the Valley Magnesite Co., 65 miles north of Spokane, according to Irving Whitehouse, a director of the company. A third kiln has been started, increasing shipments to a carload of calcined material per day. Equipment has arrived for eight additional kilns.—Following several discussions of the war-tax on mines the Northwest Mining Association adopted resolutions expressing belief that the "law in its effect on the mining industry is unequal and unjust and in some cases oppressive and confiscatory. Neither this association nor the mine-owners object to any tax, however onerous, in aid of the present righteous and most necessary war, but it is only common justice that inartificial standards be corrected so that the tax upon mining be equalized with that of other industries and that the mines, as between them-

selves, be put upon an equal and common footing in the burdens imposed upon them." The next convention of the association will be held at Spokane in February.

The Hecla Mining Co. has declared a November dividend of \$50,000. The regular rate of disbursement has been \$150,000 per month, or at the rate of 15c. per share. The Hecla is the first of the big mines of the Coeur d'Alene region to cut the dividend rate because of uncertainty of the amount of excess war profits the company would be called upon to pay. The latest disbursement will increase the total of distributions to \$6,855,000, of which \$1,400,000 will have been paid this year. What is said to be a record in driving has been made at the Armstead mines on Lake Pend Oreille, in the Idaho panhandle. In 29 days of October the main adit on the property was advanced 488 ft., maintaining an average of 17 ft. per day. Ordinarily a rate of 12 to 15 ft. is considered fast progress in north-western mines. Everything essential to scientific mining is being used in driving at the Armstead. The track is equipped with 20-lb. rails, which have been laid as carefully as if for a steam-railroad. Storage-battery locomotives are used in hauling and the ore-cars are equipped with roller bearings. The machine-drills are of large size and power. A bonus is paid for each foot over 300 driven per month.

## PLATTEVILLE, WISCONSIN

ZINC, LEAD, AND PYRITE SALES.—PLATTEVILLE, CUBA, AND BENTON DISTRICTS.

Prices for zinc ore were well maintained during the first half of the month, namely, \$67 per ton base for premium and top grades with the range down to \$62 for the inferior grades down to 54% zinc. The first appreciable break came about October 20, when the top quotation receded to \$62 per ton base with the range down to \$57. Exchange quotations held to these figures, but local correspondents in camps where refineries are situated and deliver top-grade ore showed a wide discrepancy in figures, proving that the published figures did not entirely reveal inside buying conditions, Linden at one time quoting \$56 per ton for 60% blende. The closing days of the month found the base on premium grades back to \$65 per ton, with the range for the lower grades down to \$59 per ton.

The lead producers adroitly managed to evade current quotations for ore all the month and the shipment made of six cars in all in no wise reflected offerings published in trade and metal-market journals. The determination to keep out of the market did not at first seem well taken, as the production was by far the best shown for any month of this year, and a reserve had accumulated in the field estimated at 1500 tons. It appears that miners have confidence in later demands and are willing to carry lead ore over until next spring if necessary, as most of the ore secured in this field is obtained through wet concentration of zinc-lead ore. There are few exclusive lead-ore producers in the Wisconsin field.

Shipments of iron pyrite were small but steady during the month. The demand improved, but there was no appreciable change in price. Spot prices for sulphuric acid ruled as follows: 60°B., \$20 to \$25 at maker's work; 66°B., \$30 to \$35.

Shipments of carbonate zinc ore were confined to deliveries made by the Mineral Point Zinc Co., on which quotations did not apply. The standing offer of \$25 per ton base of a 40% zinc content found little favor with miners and less of this class of ore is being mined than at any time in the history of the field. A scarcity of miners in the northern districts is responsible at present for many good producers being idle. This ore is used exclusively in the manufacture of zinc oxide for paint, heavy shipments were made daily from Mineral Point to army cantonments.

The deliveries of ore, reported by districts, from October 1 to 27 were:

Districts	Zinc Lb.	Lead Lb.	Pyrite Lb.
Benton .....	20,506,000	262,000	.....
Mifflin .....	6,838,000	.....	.....
Galena .....	4,272,000	170,000	.....
Linden .....	2,020,000	88,000	508,000
Hazel Green .....	1,626,000	.....	.....
Shullsburg .....	1,355,000	.....	.....
Platteville .....	1,006,000	.....	.....
Highland .....	840,000	.....	.....
Potosi .....	348,000	.....	.....
Dodgeville .....	346,000	.....	.....
Cuba City .....	240,000	.....	4,910,000
Mineral Point .....	224,000	.....	.....
Total .....	39,621,000	520,000	5,418,000

The gross recovery of crude concentrate from all mines totalled 19,964 short tons; the total net deliveries to smelter were 13,001 tons. While there was about the same recovery of crude ore for September the net deliveries exceeded August by 1300 tons.

The shipments of high-grade refinery ore made during October were: Mineral Point Zinc Co., 5,218,000 lb.; National Separators (Cuba), 4,506,000; Wisconsin Zinc Roasters, 3,986,000; Linden Refinery Co. (Linden), 330,000; Benton Roasters, 426,000; a total of 14,466,000 pounds.

Distribution and sales of zinc ore were: Mineral Point Zinc Co., 5950 tons; Grasselli Chemical Co., 3081; National Separators, 3078; Wisconsin Zinc Co., 3265; American Zinc Co., 1996; American Metal Co., 1440; Linden Zinc Refiners, 882; Benton Roaster Co., 707; Matthiesen & Hegeler Zinc Co., 634; Illinois Zinc Co., 513; Lanyon Zinc Co., 338; Edgar Zinc Co., 338 tons.

In spite of bad weather, which retarded mining operations considerably, a good showing was made in all branches of the industry. Lack of sufficient labor to man mills was responsible for the shutting down of two mills in the Highland district. Forces were kept at work underground and shipments were maintained without interruption. The Saxe-Lampe mine resumed regular deliveries after a period of idleness due to the opening of recently-discovered deposits. The Linden camp was more active than usual. A new shaft was bottomed in ore on the Treloar mine for the Milwaukee-Linden Development Co. The Spring-Hill Mining Co. broke into new deposits on the side of the old Mason mine. The Optimo Mines No. 3 and 4 produced steadily and a new shaft was put down on No. 4; a mill and power-plant is to be built on the site of No. 4. Roos Bros. made improvements to power and milling plant. Stoner Bros. Co. re-milled old dumps found on the Anaconda mine, securing a high-grade concentrate.

The zinc oxide and acid departments of the Mineral Point Zinc Co. were active all the month. The two reduction plants operated constantly and the shipment of high-grade blende to smelters was heavy. Considerable far-western low-grade calcined blende and carbonate-zinc ore from Mexico were received at the works. The North Survey Mining Co. of Dodgeville was the only active ore producer in this district.

The Mifflin district made a good showing both in output and deliveries. The two Coker mines and the Yewdall claimed the lion's share of attention. The Grunow Mining Co. made regular deliveries. The M. & A. Co., operating the Big Tom, shipped two and three cars of zinc ore per week and paid a 25% dividend. Lucky-Six, Biddick, and Peacock were regular shippers.—The Block-House Mining Co. shipped frequently and the close of the month found 20 cars of refinery ore held in bin, for which bids were solicited in open market. The company paid a 100% dividend on October 15. This concern has paid \$134,000 in dividends since starting, only a year ago, on a capitalization of \$20,000.

## ALASKA

(Special Correspondence.)—William Martin, of the Alaska Free Gold, left for Seattle on October 16. He states that plans are under way to finance the construction of a hydro-electric power-plant to deliver power all the year and supply all producing mines, which, under present conditions, are only able to operate about 120 days in the year.—Steel on the main line of the Government railroad will be laid to Montana creek within the week, when the track-laying gang will be laid off for the winter.

Anchorage, October 22.

(Special Correspondence.)—A suit to recover \$16,500 has been filed against the Eagle River Mining Co. The company is controlled by Georgia capital and has been operating the mine at Eagle River for a number of years. Last summer the work was closed down and the property has been idle since. B. L. Thane, C. C. Whipple, and the Alaska Gastineau Mining Co., with various Juneau merchants, appear among the plaintiffs.—A rich discovery of gold is reported from Good News Bay in the Kuskokwim district. A stampede is on from Bethel.—The Government will let a contract for mining 200 tons of coal from the Nenana fields for test purposes.

Treadwell, October 26.

The Westover group of copper mines in south-western Alaska is said to have been sold to the Chitina Exploration Co. of Seattle, for \$516,000.

The Gold Bullion mine, in the Willow Creek district, has closed down after a successful season, and for the first time in several years will not employ any men during the winter months. The mine has been under lease by a syndicate of Canadian capitalists and has been managed by A. T. Budd. Mr. Budd and his crew of workers came to Anchorage on October 26 and left for Toronto two days later. The Canadian syndicate, Mr. Budd said, had surrendered its lease, although the mine has paid a handsome dividend as the result of this season's operations. The majority of stock in the company owning the mine is held by Frank Bartholf, of Denver, and the property will be operated next season by the company owning the ground.

Walter McRay, a deep-sea diver of Tacoma, Washington, proposed to the copper mining people at Cordova that he recover the ore that had been dropped overboard in loading ships for one-half its value. They told him he was welcome to try, and hoped he would be lucky enough to make fair wages. Hundreds of tons of copper annually has been lost overboard during the loading of ships at that place, and no previous effort has been made to recover it. An official report states that McRay has so far earned a trifle over \$5000 per month as his share.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—The Phelps-Dodge corporation is employing all available forces in the Tombstone district in mining manganese ores.—L. D. Ricketts, consulting engineer for the Calumet & Arizona, will take charge during Major Greenway's absence.

Bisbee, November 1.

Complete agreement has been reached between the President's Mediation Commission and the mine operators of the Warren district. The plan, which will go into effect immediately, provides that no man shall be refused employment because he does or does not belong to a union, and makes provision for adjustment of disputes through grievance committees composed of men actually employed by the companies. Disputes that cannot be settled by the committees to be adjusted by Federal mediators whose decision shall be final.

### GILA COUNTY

(Special Correspondence.)—The Old Gibson mine at Bellevue has been sold to a syndicate of Eastern capitalists who have organized the Gibson Consolidated Copper Co. The company proposes to erect a 300-ton mill. The Gibson mine has a record of \$2,100,000 in smelter returns.—The Porphyry Copper Co. has resumed operation.

Globe, November 2.

### GREENLEE COUNTY

(Special Correspondence.)—The Federal Board of Investigation, which has been in the Clifton-Morenci-Metcalf district, has brought about a settlement and has adjusted the differences between the copper companies and the miners. The companies announced on November 3 that the strike was settled and that operations would be resumed. The miners are applying for work as individuals. The conditions upon which the mines are opening are practically the same as before the strike.—Owing to the general overhauling of the mill at Morenci, the largest mines of the Arizona Copper Co. at Metcalf will not be operated for some time. Only high-grade ore will be mined for the present.—A few of the Americans who left to seek employment during the strike have returned to the district and many more are expected. As but few Mexicans left, labor shortage is not expected to be serious.

Metcalf, November 5.

### MOHAVE COUNTY

(Special Correspondence.)—It is reported that leading stockholders of the Washington-Arizona Mining Co. will begin work on the Lady Anne group of claims, just south of the Washington-Arizona.—The Jamison mine is opening up some good gold-silver-copper ore on the 300-ft. level. This ore will run \$15 in gold and 6% copper.—The Golconda Annex of the Union Metals Co. will drive under the Black Butte to develop the surface showings.—The Distaff mine is being unwatered.—A rich strike of ore has been made in a winze sunk on the Prince George mine by the Arizona Butte company. The ore is 4 ft. wide and averages 128 oz. of silver. This ore is well below the old workings; an adit is being driven to cut the orebody at a deeper level.—The output of the Tom Reed mine has been increasing, the bullion output for the first half of October being \$34,000.

Kingman, November 2.

### \* PIMA COUNTY

(Special Correspondence.)—E. Cripin of Tucson has under bond and lease the Shacklette-Upshaw group of four claims in the San Xavier district.—G. W. Warren and associates of New York have purchased under bond and lease a group of

elven claims in the Twin Buttes district from Mike Serasio. Drill-holes have shown ore carrying 11.37% copper and 7 oz. silver. Contracts for 2000 ft. of bore-holes are to be let immediately.—The Sahuarita smelter is being rehabilitated by lessees from the Pioneer Smelting & Mining Co., and it will be ready by the end of the year.—G. Ulter and Bisbee associates have taken over the old Gunsight mine. The old shaft will be re-timbered. It is claimed there is an orebody some 200 ft. wide carrying 4% lead.—Grading for the spur-track connecting the smelter and leaching-plant is being done.—An old vein of \$20 free-milling gold ore has been uncovered in the old Mammoth mine in the Casa Grande district.

Tucson, November 1.

#### YAVAPAI COUNTY

(Special Correspondence.)—Operations at the United Verde Extension are proceeding rapidly. One blast-furnace of the new smelter will be blown-in next month. The branch of the railroad that is to convey the ore from the main adit to the smelter is rapidly approaching completion.—A six-drill compressor and 60-hp. hoist are to be erected at the Jerome-Superior.—A syndicate of Jerome and Prescott investors has secured an option on a large part of the Verde Apex stock and undertaken the financing of a company. This property is about one mile to the south of the United Verde.—Recent developments in the shaft sunk on the line of the Socrates claim of the Venture Hill company are encouraging.—The New York Verde has taken over the claims of the Victor Copper Co. in the Verde district and the Maynard district of Mohave county.

Prescott, November 2.

(Special Correspondence.)—The Arizona Binghamton Co., locally known as the A B C company, has gone through 31 ft. of high-grade copper ore in the new cross-cut on the 600-ft. level, most of the ore being rich enough to ship to the smelter. The cross-cut on the 600-ft. level has cut a strong vein of ore; it is a continuation of the same vein that has been found on all of the upper levels, and settles the question of the permanency of the orebodies.

The Patton copper mine, situated four miles east of Mayer, has been taken over by the newly-organized Rio Tinto Copper Mining Co. W. D. Mahoney and P. J. McIntyre, of Jerome, are the principals of the new company. The property is well developed and considerable high-grade ore has been exposed. The company will be sufficiently financed to carry out extensive development work.—The Copper Mountain Mines Co. is working a force of a dozen men in the old Stoddard mine at the north end of Copper mountain. A gas hoist has been erected and one of the old shafts is being re-timbered. This company is a re-organization of the old Stoddard Copper Co. which operated extensively a quarter of a century ago. The new company is capitalized for \$5,000,000. The old mine is one of the best developed on Copper mountain; many shoots of high-grade and milling ore are exposed; these were developed when only rich ore could be handled economically. The close affiliation of this company with the Arizona-Binghamton, a mile to the north, will mean that the experience of developing the lower workings of the Binghamton will be used in the development of the old Stoddard mine. Celora Stoddard is president and general manager of the new company, Senator Reynolds of New York vice-president, and M. A. Pickett, of Phoenix, is secretary and treasurer.—There are indications of ore in the adit that is being run on South Copper mountain by the Monte de Cobre Copper Co. This is the mine that was taken over last summer by W. A. Tucker, John Ross, and James Smith, of Bisbee. The adit is being run to tap a strong vein of copper ore on which a shaft has been sunk for 60 ft. The formation has changed and some chalcopryite has appeared in the last drillings.—The announcement made by the Black Canyon Mining Co. that a flotation-mill is to be erected at the mine,

five miles below Turkey, means a great deal to this silver-lead camp. The mine was originally located by J. D. Thompson, of Prescott, eight years ago. Thompson partly developed this Black Canyon mine and then sold it to the present Kansas City owners, who have run a drift about 800 ft. on the main orebody opening a strong vein from 8 to 16 ft. wide. There is about 300 ft. of good ore above the drift. W. A. Moses is president, A. L. Harroun vice-president, Edna Harroun secretary, and Claude Baker general manager.

Mayer, November 10.

### CALIFORNIA

#### NEVADA COUNTY

(Special Correspondence.)—The North Star Mines Co. has re-constructed a 40-stamp mill at the Champion mine and enlarged the cyanide plant. The deep Providence shaft has been splendidly equipped and converted into the main working outlet. Work will be pushed more vigorously in the Nevada City mine, and in other claims that have been developed to comparatively shallow depths.—The shaft of the Allison Ranch mine, four miles below Grass Valley, has been unwatered to a point below the 800-ft. level and the management is preparing to repair additional levels and start deeper development work. The mill is now running with two shifts, most of the ore coming from the 400 and 700-ft. levels. Several promising blocks of ground are being worked by lessees.—With possible exception of the Red Ledge mine, all properties in the Washington district have suspended chrome shipments for the winter because of unsatisfactory road conditions. In the Red Ledge a large body of chrome has been found in an open-cut and has been quarried to fair depth. It is pronounced the best chrome deposit yet discovered in Nevada county. Upward of 6000 tons of high-grade chrome has been shipped from properties above Nevada City in the past six months.—Copper mining is active around Smartsville with several claims producing. From the Dibble group, owned by William Dibble of Grass Valley, regular shipments are going to the Kennett smelter. San Francisco people are inspecting the field. Most of the ore carries gold as well as copper.

Nevada City, November 12.

#### SHASTA COUNTY

Confirmation is lacking of the extensively reported discovery of a 7-ft. seam of coal on Beegum creek in the south-west part of this county.

#### SIERRA COUNTY

(Special Correspondence.)—Preparations are being completed for an active season at the Brandy City hydraulic mine, near Brandy City. Flumes and ditches have been improved, the restraining dam strengthened, and much new ground prepared for hydraulicking. Four to six giants will be operated as soon as sufficient water is available.—All surface work has been completed at the North Fork and Wisconsin mines near Forest, and underground mining has been resumed at both properties. The Wisconsin has been equipped with one of the best electrical plants in the county. Although under separate management, both mines are worked from the same main adit. Driving on the new vein is proceeding in the North Fork, the work being conducted from the shaft, which has been thoroughly repaired.—An electric hoist and compressor have been shipped from Nevada City for the South Fork mine, near Forest. A promising quartz deposit has been opened near the main adit of this property and is showing ore of excellent grade. Preparations have been made for sinking as soon as hoist and compressor are ready for service, meanwhile driving for the Bald Mountain gravel channel will continue.

Downieville, November 10.

R. G. Matzene and Mrs. Matzene, of Syracuse, and Richard

Phelan, of Oakland, have bonded the Hilda mine at Sierra City. The Hilda was equipped some years ago as a hydraulic mine, but the California Debris Commission stopped operations because there were no restraining dams. In future the mine will be worked as a drift-mine.

#### SISKIYOU COUNTY

(Special Correspondence.)—While some prospecting and staking of claims throughout this county is going on, but little actual work will be attempted on new properties until next season. The suspension of assessment work leaves but few mines working at present.—W. R. Beall, of the Know Nothing mine near the Forks of Salmon, expects to resume operation with new machinery in two weeks. He has been handicapped in not being able to get the new equipment delivered.—The Mercury Company of America, under the management of Eugene C. Belknap, will soon begin operation with new equipment on its Cowgill cinnabar mines, at Gottville, near the head of Beaver creek.—Henry Musgrave and Albert Hadley are taking out considerable high-grade chrome ore at Lime gulch in the Greenhorn district. F. Le May is also operating on chrome deposits near their mine.—T. K. Anderson of Gottville, operating the Pilot Knob gold mine on Empire creek, is erecting a new gasoline engine to run a 5-stamp mill.—W. B. MacAdams of Yreka will operate hoists and pumps on his placer mine near Gottville by water-power this winter. J. R. Clute and W. J. Beagle are operating a 2-stamp mill on a rich gold deposit near Gottville.—All the placer mines through this district are in shape for activities as soon as the rains start.

Hornbrook, November 9.

### COLORADO

#### BOULDER COUNTY

(Special Correspondence.)—J. C. Clark has secured control of the Grand Group Silver mines at Caribou; he is erecting machinery on the Grand County shaft, which is about 300 ft. deep. The Grand Group consists of seven claims and is one of the oldest properties in the district. It has produced heavily and is reported to have shipped some of the richest ore ever produced at Caribou. It adjoins the famous old Caribou on the north. Extensive development work will be done in re-opening the old ore-shoots and exploring for new deposits.—William Wilson, who has a lease on the Wolcott group, just above the Lucky Two, has one of the largest bodies of tungsten ore in Boulder county. The high-grade ore runs from 28 to 35% and the low-grade from 2 to 4%. Heavy shipments are being made and the property is being worked to its full capacity. Among other lessees on the Wolcott holdings are the Sellers Bros., who are operating an extension of the Eureka vein; Yates and Starkey in the Blue-Jay adit; and Harris, Tripp, and Premier, the Tip-Top, which is an extension of the Eureka. Regular shipments from these properties are being made.—A big body of free-milling gold ore has been discovered at the Huron property.

The Dana Mining Co. has been organized with headquarters at Boulder. It is giving most of its attention to the development of the old Hoosier mine at Summerville. James E. Simpson, of Boston, is president; Captain Coan, of Boulder, secretary-treasurer; and A. S. Sloan, manager. The Hoosier was one of the principal producers of the early days.—W. R. Baker, the veteran miner at Caribou, was in Boulder a few days ago. He is greatly pleased with the revival in silver mining and the good showing which has been made in the mines of the Caribou district. James Cowie, president of the Cowie Coal Co., reports that its new mine near Gorham should be ready to begin production within the next two weeks.—W. F. Harpel, manager for the Consolidated Leasing Co., at Eldora, is pushing work on the company's new mill.

Eldora, November 5.

#### LA PLATA COUNTY

On November 1 the plant of the American Smelting & Refining Co., at Durango, closed. F. C. Gilbert, the manager, has made the following announcement.

"In retiring from the business we beg to express our appreciation for the co-operation which the shippers of the district have extended to our venture.

"Great progress has been made in the art of milling the San Juan ores and we believe that the problems which seemed so difficult two years ago are now practically solved. Since we started in the business the custom-mill idea has spread and we are convinced that the interests of the camp will be well taken care of by the small mills located at favorable points. The increased tonnage of both concentrates and crude ore has necessitated an increase in the roaster-capacity at the Durango plant. We predict for 1918 the biggest tonnage in fifteen years."

#### SUMMIT COUNTY

The property of the Michigan Mining & Milling Co. on East Sheep mountain near Kokoma has been shipping steadily

PART OF COLORADO

to the smelter at Leadville. The ore runs from 20 to 30% lead and carries from 12 to 15 oz. of silver. The mine has been opened by two adits, the lower one being now used as the main working-adit. The mine is equipped with an air-compressor and an underground hoist draws ore from the long incline driven on the orebody. All machinery is driven by electric power furnished by the Colorado Power Co. Edward Moir is president, S. H. Dunlop manager, and John M. Moir and G. E. McKim are directors.

#### TELLER COUNTY

(Special Correspondence.)—Dividends in the sum of \$183,500 were paid on November 10 to stockholders of the following Cripple Creek mining companies: Cresson Consolidated \$122,000, Golden Cycle Mining & Reduction Co. \$45,000, both monthly dividends, and the Granite Gold Mining Co. \$16,500, a bi-monthly distribution.—Recent development at the bottom or 1600-ft. level of the shaft of the Cresson company has exposed a huge body of ore of an average value of one ounce gold per ton. Ore at this point in the levels above has been too poor to pay for shipment.—The October production from properties of the United Gold Mines Co., the Trail, W. P. H., and Bonanza mines on Bull and Ironclad hills and Battle

mountain, totalled 84 cars with the content closely approximating 3000 tons, averaging \$21 per ton. The Trail mine was the heaviest producer with 67 cars shipped by three sets of lessees.—The properties of the Requa Gold & Silver Mining & Milling Co., a corporation controlled by the United Gold Mines Co., the charter of which has expired by limitation, will be offered for sale at the Court House in Cripple Creek on November 30 by G. R. Lewis, trustee appointed by the district court of Teller county. The properties consist of the Trail mine on Bull hill and the Big Banta, Old Ironsides, and Lost Fraction on Battle mountain containing 25,338 acres, U. S. Mineral Survey No. 7812. An important discovery has been made in the bottom level of the Modoc inclined shaft at a depth of 1150 ft. An ore streak, on the west vein about 4 in. wide of tetrahedrite or gray copper, assayed 88 oz. gold and 100 oz. silver per ton.

Austin T. Holman, formerly superintendent of the Golden Cycle mine, and more recently identified with the J. T. Milliken interests in Alaska, has been appointed superintendent of the Granite G. M. Co., to succeed the late D. L. McCarthy.—E. M. Rapp, a graduate of the Colorado School of Mines, has been appointed superintendent of the Ajax mine for the Carolina Mines Co., lessee.—The hoisting-plant at the Ajax was wrecked last week, when the skip passed beyond control of the engineer and crashed to the bottom of the shaft. The damage to plant and shaft has been estimated at \$10,000.—J. T. Alexander of Elkton has been appointed superintendent for the Queen Gold Mining Co., operating the Eclipse mine on the south-western slope of Battle mountain. The Queen is controlled by J. T. Milliken. John Lynn, late superintendent of the Queen, has left Colorado for Los Angeles and will remain with the Milliken interests in California.—The properties of the Sedan Gold Mining Co., on Galena hill, the Anna Belle, Fourth of July, and McGee lodes, containing 13,738 acres, will be sold under a judgment issued from the district court of El Paso county, in the sum of \$19,861.65 in favor of A. B. Crane, on December 8.—The district mines are working short handed and with excessive cost of mining supplies, few leases are active, and production is maintained by operation of the larger corporations and their lessees operating under the split-check system.

Cripple Creek, November 8.

## IDAHO

### SHOSHONE COUNTY

A mining case that will occasion wide interest throughout the West and which involves hundreds of thousands of dollars began November 7 in Federal Court, Judge Wolverton presiding, the litigants being the American Smelting & Refining Co., a New Jersey corporation, and the Bunker Hill & Sullivan Mining & Concentrating Co., an Oregon corporation. An injunction is sought by the American company to restrain the Bunker Hill company from making other disposition of its ore and concentrate than the delivery at the smelter of the plaintiff corporation. The Oregon corporation owns the Bunker Hill mine, of the Coeur d'Alene district of Idaho.

A 25-year contract, entered into between the two companies, and which has half its term yet to run, provided for the delivery of all ore and concentrate from the Bunker Hill properties to the American smelter. About a year ago the Bunker Hill company began the construction of a large smelter of its own near the mine. The American corporation alleges that to divert any portion of the contracted supply would work great injury to its business, inasmuch as the Bunker Hill ore contains certain elements that have been counted upon for the smelting of gold and silver ores received from other mines. The plaintiff sets forth that it would be injured, not only by the loss of business, but by the retarding of its other smelting operations, owing to a shortage of the Bunker Hill ore, which contains a low percentage of zinc and is needed to reduce the

proportion of zinc in other ores received for smelting.—The profits of the Bunker Hill company during the first half of the contract period have been \$200,000 per month, it is alleged, while the mining company has paid to the American Smelting & Refining Co. approximately \$15,000,000.

The Federal Mining & Smelting Co., operating in the Coeur d'Alene and Wood River regions of Idaho, reports earnings of \$112,422 in September, after all deductions. This is an increase of \$16,455 over the net earnings for September 1916, which were \$95,967. The earnings in July were \$259,728, June \$276,533, May \$217,016, April \$204,581, March \$151,664, and January \$77,791. The net profits for the year to September 30 last were \$1,368,930, as compared with \$720,596 in the corresponding period in 1916. Three dividends of 1½% each, amounting to \$209,757 each, have been paid on preferred stock during the year. An addition of 350,000 tons, by estimate, has been made to the ore-reserves by deepening a shaft and workings in the Coeur d'Alene region during the summer.

## MONTANA

### LEWIS AND CLARK COUNTY

(Special Correspondence.)—The Marysville Gold Syndicate, which is developing numerous mining claims east of the Shan-

non and which owns the Bald Mountain and Belmont claims, has entered into arrangements with the St. Louis Mining & Milling Co. at Marysville to mill 30 tons of ore per day. The ore will be taken from the Honeycomb and Mt. Pleasant veins. This arrangement is regarded as only temporary, as the syndicate purposes building a plant of its own in the spring. A. B. Woolvin, who was connected with several large mining deals in Montana, is the main promoter of the enterprise. The capital is being furnished by Duluth, Minnesota, people.—The Barnes-King Mining & Development Co., whose principal mines are in Marysville camp, is producing at the rate of about \$100,000 per month.—The Helena mine, in Grass Valley, has sent out ore to the East Helena smelter, for which it has received \$18,000. The ore was mined from the 300-ft. level.—The Rock Rose and Cruse Con. mines have lately shipped two carloads of lead-silver ore to the smelter.

Two carloads are being shipped from the Coffee-Byrnes claims, Grass Valley. Part of the ore will run from 400 to

500 oz. of silver per ton. The other half is lower grade, running about \$50 per ton.

Helena, November 5.

## NEVADA

### CLARK COUNTY

A check for \$7070, exclusive of the freight, which amounted to nearly \$1100, has been received for one car of ore which the Boss company shipped to Irvington, New Jersey, several weeks ago. In future the ore from this mine will be sent to the Pacific Platinum Co. at Los Angeles, which started operations late in October.

### ELKO COUNTY

The Holden Mining & Milling Co., whose stock is owned by the Stewart Mining Co. of Idaho, is operating the Commonwealth, Nevada, McVystal, Surprise Fraction, Diana or 16 to 1, and Extra or May Queen mines in Tuscarora. At present 16 men are working and the force is being increased. A new mill is to be erected this winter; the treatment will be ball-mill crushing followed by electro-cyaniding. The directors of this company reside in New York. J. D. Hubbard is general superintendent at Tuscarora.

### MINERAL COUNTY

(Special Correspondence.)—For the year ended October 30, 488 carloads of ore, aggregating 25,672 tons, and of an estimated value of over \$1,000,000, was produced in the Luning district. One carload averaged 42% copper and 12 oz. silver, or about \$275 per ton at the then prevailing prices. Little, if any went under 5% copper. The principal shippers were the Kirchen Mines Corporation, Wedge Copper, Calavada Copper, Pilot Copper, Congress Copper, Luning-Idaho, Wall Street, Fermina Sarrias estate, R. B. Todd Mining Co., and the Iriquois Copper Co. About 20 companies are operating in the district and upward of 100 lessees have been at work during the past year. The deepest working, namely 1100 ft., is at the Calavada on the 1000-ft. level and it is the best showing in the Luning copper belt. The orebody here is 10 ft. wide and will average 15% copper. A strike has been made on the 260-ft. level at the Giroux, the vein is over 10 ft. wide and will average 10% copper.—In addition to the high-grade shipping ore, all the mines have orebodies of good mill ore that should pay well with a local reduction plant. V. C. Alderson, president of the Colorado School of Mines, reports that the Pilot company alone has 298,100 tons of ore blocked out on four sides that will average 2.51%, and he believes that many times that amount will be developed. It is probable that a big plant will be built in the near future at Luning.

Luning, November 10

### NYE COUNTY

(Special Correspondence.)—The Cash Boy company has arranged to ship regularly to the Mammoth smelter, at Kennett, California; the ore will average \$25 per ton in silver. The cross-cut from the 1700-ft. level has cut the foot-wall section of the vein, disclosing a width of six feet. East and west drifts open the vein on its strike. Good ore continues to be found in the main upper workings.—The Belmont company is adding conveyors and sampling equipment in its Tonopah plant and will be ready to treat custom ore before the end of December. The Millers plant will be dismantled. On the 700-ft. level the faulted segment of the South vein has been uncovered. Approximately 2491 tons is shipped weekly to the mill. The general manager, Frederick Bradshaw, has gone to British Columbia to inspect the Surf Inlet mine.—The West End company is concentrating work on its California claim where the Ohio vein has developed into the principal ore-producer of the property. On the 500-ft. level the cross-cut has shown the vein to be fully 15 ft. wide, and the ore of excellent grade. A drift is advancing in a full face of ore and a cross-cut from the

555 intermediate has entered the orebody. The management is preparing to develop the vein at further depth.—The Nevada Ophir Mining Co. has resumed work at its silver mine near Millet, with R. J. Williams as superintendent. The property has been idle for 40 years; it is stated to contain large quantities of medium-grade ore. It is planned to work the property through a series of adits.—An ore-shoot showing considerable free gold has been tapped on the 400-ft. level of the Manhattan Consolidated. It was uncovered in a cross-cut from the 175-ft. east drift, 200 ft. from the shaft. Developments are proceeding from several points on the third and fourth levels.

Tonopah, November 10.

### STOREY COUNTY

Encouraging reports continue to come from the north end of the Comstock, especially at the Union Con. mine, where further important developments have been made the past few days. On the 2300-ft. level, from the north drift an east cross-cut, which is being extended in the direction of the hanging wall of the vein, has broken into good ore, and the last car-samples show an average of \$25 per ton. There is also an improvement working south from the east cross-cut on the 2400-ft. level, where the last 16 cars of ore taken out in the advance gave an average of \$35.50 per ton. Three feet in the face has given samples of \$110 per ton, and three feet next to it \$10.

Developments are also being made in the Ophir mine, where work is being carried on to the south from No. 1 cross-cut on the 2100-ft. level. This drift was started to follow a 3-in. quartz stringer, which has now widened out to 14 in., and assays \$18 per ton. In the Mexican mine on the 2900-ft. level, the cross-cut is showing more quartz with some clay seams, the formation heretofore being in hard ground. The Sierra Nevada has started to clean out and repair the east cross-cut from the main north drift on the 2500-ft. level, which leads to an ore-discovery made in the early days and which is to be further investigated, as reports show little or no work done there. Work continues in the 2600-ft. raise.—The Andes is working on the 350-ft. level at the stope and south, extracting some low-grade ore.—Alpha and Exchequer are prospecting on the 200-ft. level from the Imperial shaft.—The Jacket Crown Point-Belcher Co. on Gold hill is placing the mill in shape; part of the plant is in operation.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—The output for October on Pacific mine amounted to 390 tons.—The Mogollon Mines Co. is now handling custom ores and greatly relieving the congested milling situation of the district. During the week the Oaks Co. made regular shipments from the Maud S., Deep Down, and Eberle mines of the Central group. Another burro train was added to the freight service.—The Socorro M. & M. Co., which recently lost the upper portion of the plant by fire, is pushing plans for immediate re-building. The shaft collar is being re-timbered and building material is expected. The filters, refinery, agitators, and pumps were uninjured and the regular clean-up has been made. October was to have been the largest production the company has had and the recent splendid ore opened in the lower levels makes the delay doubly unfortunate.—All mines are crowding in their winter freight and both teams and trucks are working to capacity.

Mogollon, November 6.

## SOUTH DAKOTA

### LAWRENCE COUNTY

(Special Correspondence.)—With the resumption of work at the Silver Queen property, the Galena district is once more taking on the aspect of old times when daily shipments of

high-grade lead-silver ores were common. Within the past month ten cars of ore were shipped from the Silver Queen to the smelter at Denver. This material was all taken from the dumps and netted the owners satisfactory returns. Work has been started in the mine and several high-grade bodies of ore are being developed.—The New Puritan Co. is adding machinery to both mine and mill at Strawberry Gulch and the 100-ton cyanide plant will be in operation soon after the first of the year. For the greater part of the present year the mine has been undergoing development.—Excavation for the 10-stamp mill and concentrator to be erected in Spruce Gulch below Deadwood, by the Deadwood Zinc & Lead Co. is nearly completed. The ore, which is exposed in several places on the property, is a heavy sulphide containing lead, zinc, gold, and silver.—At a meeting held at Deadwood on October 12 there were present R. R. Horner, a mining engineer in the U. S. Bureau of Mines, and Thomas Varley, superintendent of the Experimental Station at Seattle. These men have been sent to the Black Hills by the Federal branch to investigate the tin deposits of that district. The purpose of the meeting was for the Government officials to meet the mining men. While it has been known for some time that there were large deposits of low-grade tin ores in South Dakota, the development and production of the metal has been limited. Within the present year 20 tons of tin concentrate averaging about 50% metal was produced in the Hill City district and sent to the Eastern market. Most of the ore was taken from the Cowboy mine.—O. M. Lane of Keystone continues the production of spodumene at the rate of one car per week. The Rheinboldt Met. Co. is taking out the same amount of amblygonite weekly. At the Summit mine west of Hill City, the Dakota Continental Copper Co. has commenced diamond-drilling to further develop the ground. The shaft is down over 200 ft. and several hundred feet of cross-cut work has been completed since the first of the year.

Lead, October 26.

## CANADA

### BRITISH COLUMBIA

The production of the Phoenix mines of the Granby Consolidated Mining, Smelting & Power Co., in the Boundary district, averaged 13.52 lb. copper, 0.177 oz. silver, and 0.027 oz. gold per ton, according to the annual report. The development cost averaged 16c. per ton and 12.2c. per foot. Diamond-drilling amounted to 6502 ft., making the total diamond-drilling on this property 119,122 ft. The cost per ton of ore on cars was \$1.17. The wage bonus amounted to 15.7c. per ton; the increase in cost of supplies over pre-war prices was 11.2c. per ton; workmen's compensation assessment, 1.5c. per ton; making an increased cost of 28.4c. per ton over pre-war prices, but this item was reduced by a 0.7c. decrease in railway freight resulting from the opening of the Kettle Valley railway. The Phoenix mines have produced 12,825,426 tons of ore, leaving reserve estimated at 3,274,996 tons, and carrying 17 lb. copper and 75c. in gold and silver per ton. Production for the last fiscal year was \$672,292 tons of ore. The company's staff and mine force at Phoenix have contributed to the War 45 men and \$42,198.35 in money, of which 75% went to the patriotic fund and most of the remainder to the Red Cross fund. The contributions during the past year amounted to \$19,440.07. Of the company's employees enlisting, five are reported to have been killed, seven wounded, and two made prisoners of war. The Granby company has taken working options on a number of properties in the Kamloops and Skeena districts and already has a force of men doing development work on them.

## KOREA

The Seoul Mining Co., operating the Suan Concession in Whang Hai Province, reports the recovery of \$140,725 for October.

# PERSONAL

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

A. W. ALLEN is at Denver.

ARTHUR WINSLOW is here from Boston.

THEODORE PILGER has returned to Butte.

J. W. MERCER is at Mokelumne Hill, California.

WILLIAM C. RUSSELL, of Denver, has gone to New York.

JAMES W. NEILL is visiting San Francisco, from Pasadena.

H. C. WILMOT is on a professional trip through Arizona and New Mexico.

GEORGE H. SEXTON, of New York, was in San Francisco this week.

C. W. LAWRE has returned from Butte to Esqueda, in Sonora, Mexico.

ERWIN W. MILLS has gone to Peking, on his return from Siberia.

WILLIAM MOTHERWELL has returned from Nelson, B. C., to San Francisco.

J. B. HARPER, manager of the Jerome Verde mine, at Jerome, Arizona, is in New York.

PHILIP L. FOSTER has been given a commission as Captain in the Signal Corps, U. S. Army.

FREDERICK H. JACKSON sails on November 20 on his return to Sydney, Australia, from Mexico.

FRANK LANGFORD, of Eureka, California, is with the Andes Exploration Co., at Santiago, Chile.

HENRY R. PUTNAM passed through San Francisco this week on his return from Shanghai to New York.

C. A. RODEGERDTS has resigned as construction engineer with the Atolia Mining Co. and is now in San Francisco.

J. D. HUBBARD, of San Francisco, is general superintendent for the Holden Mining & Milling Co. at Tuscarora, Nevada.

W. A. MELOCHE, mining engineer to the Jualin Alaska Mines Co., has resigned, to serve in the 115th Engineers, U. S. Army.

W. O. BORCHERT, of the New Jersey Zinc Co., passed through San Francisco on his way from Los Angeles to Salt Lake City.

F. JENKIN, for many years mine-superintendent and assistant-manager for the El Oro company, at El Oro, Mexico, has resigned.

GERARD W. WILLIAMS has been awarded the Military Cross for gallant service at the Somme front. He is Captain in the Royal Engineers.

BANCROFT GORE, formerly Professor of Metallurgy in the Montana School of Mines, has left Butte to go to the Naltagua smelter at El Monte, Chile.

F. L. RANSOME will take charge of the work on quicksilver for the U. S. Geological Survey in order to release H. D. McCASKEY for administrative work.

F. H. HAYES, formerly chief geologist with the Detroit Copper Co., has been appointed Major in the 79th Infantry Brigade, and is now at Camp Kearny, California.

C. B. CLYNE has resigned as constructing engineer to the Demming Mining Co., in Idaho, to accept a position with the Mine & Smelter Supply Co., at Denver.

HORACE B. PATTON, for 24 years Professor of Geology and Mineralogy in the Colorado School of Mines, has opened an office as consulting geologist at Golden, Colorado.

M. HIROKAWA, R. HAMASAKI, G. ANSAI, and S. MIYAKE, of the Metal Mining Department of the Mitsubishi Company, in Japan, are making a tour through the mining districts of the West.

E. J. CARLYLE and M. R. HULL, respectively metallurgical and mechanical engineer for the Sissert Mining Co., of Petrograd and London, have come to San Francisco from the Ural Mountain region, on their way to Salt Lake City.

# THE METAL MARKET

## METAL PRICES

San Francisco, November 13

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	16.00
Antimony (wholesale), cents per pound.....	14.75
Electrolytic copper, cents per pound.....	23.50
Pig-lead, cents per pound.....	6.50—7.50
Platinum, soft and hard metal, respectively, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	100
Spelter, cents per pound.....	10.00
Tin, cents per pound.....	65
Zinc-dust, cents per pound.....	20

## ORE PRICES

San Francisco, November 13

Antimony, 45% metal, per unit.....	\$1.10
Chromite, 34 to 40%, free SiO <sub>2</sub> limit 8%, f.o.b. California, per unit, according to grade.....	\$0.60—0.70
Chromite, 40% and over.....	\$0.70—0.80
Magnetite, crude, per ton.....	\$8.00—10.00
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.	
Tungsten, 80% WO <sub>3</sub> , per unit.....	26.00
Molybdenite, per unit MoS <sub>2</sub> .....	\$40.00—45.00

## EASTERN METAL MARKET

(By wire from New York)

November 13.—Copper is unchanged and nominal at 23.50c. all week. Lead is quiet and firm at 6.25 to 6.37c. Zinc is dull and steady at 7.87 and 7.75c. Platinum remains unchanged at \$105 for soft metal and \$111 for hard.

## SILVER

Samuel Montagu & Co., London, in their letter of October 11, state that the Bank of England gold reserve against its note-issue shows a decrease of £169,810, as compared with last week's return. In order to prevent the hoarding of silver currency caused by the increased value of silver, the Italian official gazette publishes a decree stating that the one or two lire (nominally 25 lire = \$5) silver pieces may be changed for paper money as from November 1 next to December 31. The silver currency will then cease to have a monetary value, and persons found in possession of silver pieces over 10 lire in value will be fined from 60 to 1000 lire. The sterling amount, however, involved is not large. The U. S. Mint report gave the total stock of silver Italian coin in 1913 as \$22,400,000, or 64c. per capita. It is reported that a bill has been introduced in Denmark for the issue of small money made of iron. We hear that hundreds of tons of Mexican silver dollars have been imported into the United States in the few months prior to September for melting and re-sale as bullion.

Possibility of an upward revision in the price of copper, in so far as 'high' producers are concerned, is discerned in the report of the mediators in the Clifton-Morenci copper strike. The following excerpt from the findings of the mediators would seem to indicate that where it can be shown that under the advanced wage scale a fair profit is not left to the producer, a higher than the 23.50c. rate may be granted: "If the admin-

istrator should recommend a wage increase and such a wage scale allows a fair profit to the companies under the existing price of copper, the President's commission shall at once promulgate such new wage scale and the company shall pay all such increases in wages as of the first day of the return of men to work. If, however, such a wage scale recognized by the administrator does not leave a fair profit under existing prices of copper, the President's commission shall recommend to the President an increased selling price which will yield a fair profit, and the wage increase recommended by the administrator shall not be made effective until such selling price has been obtained."

As a result of a canvass by U. S. Geological Survey to ascertain production of spelter in the United States during third quarter of 1917, C. E. Siebenthal estimates, on basis of returns of over 95% of the production, that output of primary spelter from domestic ores was 132,700 short tons and from foreign ores 23,900 tons, a total of 156,600 tons, as compared to an average of 130,569 tons per quarter during first half of 1917, 175,502 tons per quarter during last half of 1916, and 153,226 tons per quarter during the first half of 1916. Stocks of spelter at smelters September 30 amounted to 47,186 tons, compared with 33,147 tons June 30, and 17,598 tons January 1. The number of idle retorts September 30 was 64,626, or 28% of total number of retorts, and included 18 entire plants, several of which are being dismantled. One electrolytic plant also will possibly be dismantled.

# Eastern Metal Market

New York, November 7.

The markets are all dull, with sales confined to small lots. Two of the markets continue to gather strength, but the others are inactive with a tendency to become weaker.

Copper continues unchanged at the Government price and is nominal.

Tin is scarce and continues to advance.

Sellers of lead are disinclined to part with their metal, and the market is higher and stronger.

Zinc continues in poor demand and is lower.

Antimony has nominally declined.

Aluminum is weaker and inactive.

Further maximum prices on certain steel-products were announced by the Government on November 5, but they are in line with those previously fixed. The Government announces that on products not yet covered by official schedules manufacturers have agreed to adjust prices promptly. Further price-fixing is not looked for unless a general revision should be made later. Ill-advised agitation of contract-abrogation from a Government source has restricted commercial buying of steel. The feeling is that the present price-basis will not be changed on January 1, and it may be that there will be no change during the first half of 1918. Government shell-steel now under inquiry amounts to 1,500,000 tons, of which 300,000 tons was allotted last week. Pig-iron production increased in October to 3,303,038 tons, or 106,550 tons per day, as against 104,465 per day in September.

## COPPER

There is little to be said about the copper situation beyond what was contained in this letter in the past week or two. The general wholesale market is bare of sales at any price, and the distribution of supplies is entirely in the hands of the Copper Producers' Committee. Information of an official nature is impossible to obtain. Consumers are reported as being taken care of if they have Government work, and it is even stated that electrolytic copper in quantities has been delivered at the Government price to consumers doing urgent Government business but having no contracts for copper. The relation of consumption to production is a matter of speculation, some contending that the supply is not enough. Government and Allied needs are receiving first consideration. The jobbers' position continues a hard one. Small lots to needy small consumers are being daily sold at prices above the Government price of 23.50c. per lb., which we continue to quote as nominal. No interference with this practice has so far been reported. Stocks in such hands, however, are rapidly dwindling, and their replenishment at any price, or at a price to insure a profit, is problematical. A solution of this problem is hoped for in the near future. The London market is unchanged at £125 for spot electrolytic and £121 per ton for futures.

## TIN

The strong market reported last week has continued to grow stronger, due to the scarcity of spot-tin, which continues the controlling factor. Late last week a buyer desiring 15 tons could not obtain it. A prime cause is the permit situation, which continues stringent, confining purchases only to buyers whose names are given. The position of the small consumer continues to tighten, and the future of his supplies is problematical. The quotation for spot Straits on October 31 was 66c., New York, with the same price for November 1 and 2. On Monday, November 5, however, a small lot sold at 68c., New York. Outside of the spot situation the market has been quiet. On Monday moderate sales of futures were reported,

but on October 31, and November 1 and 2 there were sales of fairly large quantities of all grades of tin, mostly for future shipment, but these were not made public. Arrivals up to and including November 2 were 160 tons, with 4300 tons reported afloat. The London market is strong and higher. It has advanced £4 per ton in the last week, standing on November 3 at £260 10s. for spot Straits. The average price for tin for the month of October was 62.24c. per lb., New York.

## LEAD

In the large buying movement that followed the radical lowering of prices reported last week, probably 20,000 tons of lead changed hands. This included large quantities for France and Canada. The Government has not closed for its November needs, it is believed, but report has it that it is inquiring for a quantity for two or three months' supply. The market continues strong and higher. Prices have advanced almost daily until on Monday the quotation in the outside market was 6.25c., New York, or 6.12½c. per lb., St. Louis, for early delivery. The American Smelting & Refining Co. also advanced its price on Monday, November 5, ½c. per lb. to 6c., New York. Demand has been active in the last few days, but sales have been small, due to an absence of most sellers from the market. The leading producer has not been a free seller recently, and has even restricted the purchases of its regular customers. There is little metal available from either the independents or the leading maker. A higher market is looked for because buyers are anxious to buy, and sellers are refraining from selling.

## ZINC

Stagnation continues to dominate the zinc market. There is no life and no demand. The low sellers are the only ones parting with their metal and some of these have done so for November delivery at 7.50c., St. Louis. Others have sold at 7.75c., St. Louis, while some refuse to consider anything less than 8c., St. Louis. Brass makers and galvanizers continue out of the market, and the few orders taken do not represent any broad trading. The quotation for prime Western for November delivery is about 7.62½c., St. Louis, or 7.87½c., New York. All sales made have been of small lots only. For December delivery about ½c. per lb. higher is asked, with 7.75 to 7.87c. per lb., St. Louis, asked for first quarter.

## ANTIMONY

The antimony market continues inactive and dull. In the absence of demand we quote the market easier and nominal at 14 to 14.25c. per lb., New York, duty paid, for Chinese and Japanese grades for early delivery.

## ALUMINUM

No. 1 virgin metal, 98 to 99% pure continues to sag and is now 36 to 38c. per lb., New York, for nearby delivery with demand of small proportions. Export inquiries from Italy have appeared.

## ORES

Tungsten: There has been no change in the quotations for the various grades of ore, scheelite commanding \$26 per unit in 60% concentrate with \$23 to \$25 per unit for the other grades. The market is fairly active. Ferro-tungsten continues to be quoted at \$2.35 per lb. of contained tungsten as the minimum price.

Molybdenum and antimony: The market for both these ores in this district is quiet. The quotation for high-grade molybdenite is unchanged at \$2.20 per lb. of MoS<sub>2</sub> in 90% concentrate. There is nothing to report in the antimony ore market.

# INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

## DU PONT ELECTRIC SQUIBS

Firing explosives in mines by electricity is strongly recommended by the U. S. Bureau of Mines and other authorities. It is safer, surer, more reliable and, in most cases, ultimately more economical than the use of blasting-cap and fuse. It seems strange that miners will persist in risking serious and often fatal accidents by using 'skin-em-backs,' short squibs, and the like, for an apparent saving of a cent or two per day. Formerly electric firing was adopted only where permissible or high explosives were used. Then electric squibs were introduced which made it possible to fire black blasting-powder charges electrically, by using the electric squib, which is similar to the electric blasting-cap in construction and principle. The cap or shell is made of stiff cardboard instead of copper. It contains no detonating charge, but there is a chemical composition packed around the bridge which, when the current is sent through the bridge, flashes fire through the open end of the capsule, igniting the black blasting-powder. The Du Pont Co. has recently perfected an improved type of electric squib in which the priming charge in the new squib is more sensitive than in the old and requires less heat, hence less current to ignite it. In fact, it is almost as sensitive to heat as fulminate of mercury, so that it requires no more current to fire an electric squib than a regular electric blasting-cap. Consequently, as many of the new type electric squibs can be fired with a blasting-machine as electric blasting-caps.

While this electric squib is designed for firing black blasting-powder charges electrically, it is possible also to use the new type for firing permissible or any high explosive. The squib can be transformed to an electric blasting-cap by simply inserting No. 6 or No. 8 blasting-cap in the open end of the paper capsule and priming the explosive cartridge in the regular way. The flash of the squib explodes the cap, which in turn detonates the dynamite. By using these squibs, miners will find them of great help in eliminating dangers from premature explosions and hang-fires. It has been proved by tests that in many cases the yield is increased by electric firing. The shot cannot be fired until you so desire. There is no anxious waiting, no smoldering fuse, wet squibs, and poorly tamped holes to fear. Electric squibs eliminate the necessity of using the needle or barrel and are in line with all 'safety-first' ideas, as their use enables the miner to properly fill the bore-holes with tamping material. Du Pont electric squibs are made with either copper or iron wires. They are considerably cheaper than electric blasting-caps. The new squib can be recognized by the green paper shell or capsule.

## AMERICAN AUTOMOBILES IN CHINA

During the six years ended March 1917, Canada's imports of automobiles from the United States amounted to more than \$40,000,000. In 1912 the amount was \$6,077,497; in 1913, \$9,233,171; in 1914, \$6,459,346; in 1915, \$4,532,138; in 1916, \$5,790,498; and in the year ended last March, \$8,555,475. Canada's imports of automobile accessories from the United States dur-

ing the same periods amounted to nearly \$20,000,000, made up as follows: in 1912, \$854,000; in 1913, \$762,321; in 1914, \$3,965,173; in 1915, \$2,139,552; in 1916, \$4,693,003; in 1917, \$7,173,423. The imports of automobile tires amounted to about \$7,000,000. The annual amounts were: in 1912, \$666,411; in 1913, \$1,507,916; in 1914, \$1,263,382; in 1915, \$1,044,592; in 1916, \$1,389,400; in 1917, \$1,217,532. The 1913 reports showed that the number of registered cars in Canada had increased by 16,780, or 38%, over the 1912 registration, and in 1914 the increase was 22,070, or 36%, over 1913. After three years of war it is estimated that Canada this year is purchasing 100,000 new motor cars, almost five times as many as in 1914. The motor car in Canada is more and more coming to be considered a commercial necessity. It has aided in the movement of troops, facilitated the transportation of war-material, increased the efficiency of the farm, aided in the quicker movement of all things pertaining to business, and has been a great economic factor in the development of general business. More cars have been sold in western Canada during the past two years than in the East. British Columbia, with a population less than 500,000, scattered over wide areas of mountainous country, has automobiles in the proportion of one to every 78 of the population. The trend of the buying is shown by the fact that fully 15,000 of the increase of 23,000 cars in Ontario were priced under \$1500. A conservative estimate of the amount of money invested in private cars in Canada places it at \$135,000,000. Many large firms in the United States have established branch factories in Canada on account of the high customs duties. The automobile body and machinery are imported separately, and afterward assembled there.

## GOOD ROAD DRAINAGE

Many roads must of necessity be built across low spots or, in an endeavor to avoid a too close proximity to streams by following the edge of the bordering hills, they must cross wet spots due to seepage from higher ground. While the experienced engineer will locate the road so that these places are avoided as much as possible, it often happens that to shorten the route, prevent a sharp curve, or a heavy steep grade, he is forced to accept the challenge of draining the swampy ground. Ordinarily the construction of proper drainage-ditches in wet soggy ground is difficult. Horses, tractors, and machinery can seldom be used on account of getting mired in the mud, and hand labor is entirely too scarce and expensive to be used for such purposes. One successful road-contractor uses large amounts of dynamite in general road-work, and finds it of great assistance in ditching wet spots. He uses the electric method of firing, making the holes about 6 in. shallower than the grade-line desired, and placing them about 30 in. apart along the centre line of the proposed ditch. The charges of dynamite are primed with an electric blasting-cap, placed in the holes, and well tamped. The electric-cap wires are connected in series and fired by a blasting-machine. In this manner the entire line of charges explodes at the same instant, lifting the dirt high in the air and scattering it over the surrounding land, thus doing away with high banks of earth along

the ditch. He has become so successful at this kind of work that, by proper loading, there is no hand-work to be done after the blast, as the ditch is left clean and clear of all debris, ready for immediate use. A ditch averaging 4 ft. deep by 8 ft. wide on top can be made in this manner without the aid of a shovel. From 1 to 1½ lb. of 40% low-freezing dynamite per hole is sufficient for this size of ditch in heavy soil. The contractor claims that this method is most satisfactory from his standpoint of economy, because of its quickness, and because of the saving in hand-labor, which at this time of labor-shortage is an all important item.

## WESTINGHOUSE QUESTION-BOX

The Westinghouse 'question-box' is a resource open to all operators who have electric problems that worry them. As an example of the assistance rendered in this way we may cite the following taken at random from that department in a recent issue of 'The Electric Journal':

**ROTOR VOLTAGE.** (a) Given the locked open-circuit voltage between rings on a wound-type rotor, how is the full-load current per ring determined? (b) How is the resistance required in a starter or controller determined? G. P. S. (MINN.)

(a) The motor-current per phase (in a three-phase winding) =  $\frac{\text{Hp.} \times 746}{1.73 \times \text{volts between rings} \times X \times Y}$  Where  $X =$  (1-per cent slip) and  $Y =$  power-factor of the rotor, which for all practical purposes may be considered 100%. For example, if a 10-hp. motor had 100 volts between rings at stand-still, and had 5% slip at full load when running, the full-load current per ring would be  $\frac{10 \times 746}{1.73 \times 100 \times 0.95} = 45.5$  amperes, if

the rotor-winding was three-phase, which is practically always the case. The expression (1-per cent slip) is introduced since the secondary input determines the current with a given voltage and the secondary input =  $\frac{\text{output}}{1 - \text{per cent slip}}$  because

the slip is a direct measure of the secondary copper-loss and the secondary input must take care of the mechanical output plus the secondary copper-loss. This neglects the bearing-friction and windage, which theoretically should be added to the mechanical output, but which in general is too small to introduce an error of more than 1 or 2%.

(b) The resistance in a starter or controller depends upon (1) the characteristics of the motor and (2) the service-conditions under which it is to operate. The latter dictate the torque required on the first and succeeding notches and also the current-carrying capacity. For a three-phase secondary, the resistance will normally be divided into three equal parts or phases connected in star. The value of this resistance in ohms per phase is obtained from the following equation:

Resistance per phase =  $\frac{\text{Volts between rings}}{\sqrt{3} \times \text{full-load current per phase} \times K}$  where  $K$  equals a constant depending on the torque required on the first point of the controller. Taking for example a 10-hp. motor with 100 volts between rings and 45.5 amperes full-load current, full-load torque being desired at start,

$R = \frac{100}{\sqrt{3} \times 45.5 \times 1.00} = 1.27$  ohms. For any other torque the constant  $K$  should be changed in proportion; for example, at 50% above full load torque,  $K = 1.50$ .

ROCKWOOD CONOVER, writing in the 'General Electric Review,' says: "It is evident that in building new industrial plants after the War we must provide for a far greater expansion than ever before in the history of industrial undertakings. Not only must the layout of the buildings provide for a large expansion of assembly-floors and greatly increased space for

machine-tools and preliminary productive processes, but the areas between buildings must also be larger than ever before. Sudden expansions of business will require the erection of one- or two-story additions and lean-tos to provide additional assembly-space, or space for more machine-tools with which to get out greater products sold on limited delivery dates. Larger areas for storage sheds and platforms between shops will be required, and there must also be provision between the buildings for expansion of tracks and sidings, overhead cranes, scales, and facilities for rapid unloading of every description."

## NON-SKID ROAD-SURFACE

There has been much discussion of non-skid automobile tires, but no one has paid much attention to a non-skid road for autos. The fact is well known that a smooth asphalt surface is particularly slippery in wet weather, and for that matter almost every kind of smooth road-surface, including brick, concrete, water-bound macadam, and tar-macadam, is of this nature. Ice and sleet are particularly bad, and mountain roads are almost impassable in cold weather, owing to the sharp curves and steep grades. Even horse-drawn vehicles have difficulty in traveling over roads of this kind. In the mountainous districts of western Maryland an experiment is being conducted with a non-skid surface. This road is a tar-bound macadam on a water-bound macadam foundation. Several grades of tar-binder as a surface treatment have been previously used, but under heavy rolling and continued traffic the binder has emerged through the stone-chip covering, making a smooth surface which became slippery when wet. This year a special grade of Pontar was used on the surface as a binder, and it is hoped that a non-skid surface has resulted. The results so far have been encouraging. The binding-material used has not emerged under the roller and in regular use as have previous treatments. Under wet-weather conditions this has proved a great benefit, as the skidding of automobiles and trucks has been greatly reduced, and the footing is much safer for horses. This experiment is being watched with great interest to see how effective it is under conditions of ice and sleet. If it should be as effective as it is in wet weather a long step in 'safety-first' travel will have been made, not to mention the great saving effected on automobile tires by doing away with the necessity of using chains.

## INDUSTRIAL NOTES

The OLIVER CONTINUOUS FILTER Co. has opened an office recently in New York at 299 Madison avenue, under the management of R. G. Walker.

CHARLES A. NEWHALL Co. has added important equipment to its chemical testing laboratory at Seattle. The company also increased its staff of chemical engineers for handling a larger business in inspection and in the design and erection of chemical plants. This concern is connected with the Pittsburgh Testing Laboratory.

Harry W. Newton has joined the staff of FALKENBURG & LAUCKS, chemists and metallurgists, Seattle, Wash. Mr. Newton has had a long experience in the treatment of ores of the North-West. He first successfully solved the treatment of Republic ores, and has also done a great deal of work on ores from British Columbia and Alaska. He will have charge of the ore-testing department of Falkenburg & Laucks.

R. J. Morgan, who resigned his position with the Midvale Steel & Ordnance Co., has been appointed supervisor of sales of the AMERICAN STEEL EXPORT Co., New York. Mr. Morgan prior to his connection with the Midvale Steel & Ordnance Co. spent 13 years with the Carnegie Steel Co., and he will prove a valuable asset to the corps of thoroughly trained steel-men in the employ of the American Steel Export Company.

## TABLE OF CONTENTS

### EDITORIAL

	Page
NOTES .....	743
THANKSGIVING .....	745

The many reasons why we should observe Thanksgiving Day in a serious and grateful spirit. *M. & S. P., November 24, 1917.*

RECRUITING LABOR .....	745
------------------------	-----

The question whether it is proper or desirable to recruit miners to leave the gold mines in California for higher-paid employment at the copper mines in Arizona. *M. & S. P., November 24, 1917.*

THE LADY OR THE TIGER?.....	745
-----------------------------	-----

Fresh disturbances in Mexico; our desire for prosperity and peace across the border; the great opportunity of President Carranza; Mexico should co-operate with the allied nations, grant complete amnesty, and abolish concessions; prosperity would follow. *M. & S. P., November 24, 1917.*

### DISCUSSION

#### RECRUITING LABOR FROM THE GOLD MINES

By S. E. RAU-ROESLER..... 747  
Objections to canvassing the Mother Lode for laborers for the Inspiration mine; such efforts characterized as a violation of professional ethics. *M. & S. P., November 24, 1917.*

KING OF ARIZONA COMPANY.....	747
------------------------------	-----

A reply to Col. Epes Randolph's letter appearing in the issue of November 10. *M. & S. P., November 24, 1917.*

#### FEEDING THE MEXICANS

By J. A. PARKER..... 748  
Need of distributing food to the starving Mexicans; a means of encouraging kindly feeling in Mexico. *M. & S. P., November 24, 1917.*

### ARTICLES

#### HEAP-LEACHING OF COPPER-SULPHIDE ORE

By COURTENAY DE KALB..... 749  
Methods at Copper Queen mine, Bisbee, Arizona; im-

provements by Joseph Irving; the pyrite filter for reducing ferric iron; technique of economical precipitation of copper on iron; Dorr-mechanism adapted to precipitation; chemistry and technique of heap-leaching of copper-sulphide ore. *M. & S. P., November 24, 1917.*

MICHIGAN COPPER-TAILING .....	757

## World's Largest Ball-Mill Plant Driven by G-E Motors

This notable installation of forty-eight electrically driven Marcy Mills at the Inspiration Consolidated Copper Company, Miami, Arizona, must operate 24 hours a day for long periods.

For this, the largest installation of its kind in the world, G-E 225 h.p. induction motors were selected. These motors have high efficiency—so important for long period operation—and ample starting torque.

Practically standard construction was selected for these motors, and the selection has been justified during the last two years by an operating record which has been successful in every respect and the basis for large repeat orders.

Hundreds of grinding mills are driven by G-E motors. Among those using these motors are the Calumet & Hecla Mining Company, the Anaconda Copper Mining Company and others equally well known.

**M**ANY inquiries have been made in recent months concerning the details of the process for making zinc oxide. The question is fully answered by Mr. George E. Stone in an article which we re-print this week from the transactions of the Institute. Mr. Stone, as chief engineer for the New Jersey Zinc Company, is an authority on this as on other branches of the metallurgy of zinc.

**T**ACOMA is now able to boast the highest chimney in the world. The stack of the copper smelter is 571 feet high. It is constructed of paving brick, which is suitable for the purpose because this material is able to withstand a high compressive strain, moisture, and acid. The height is advantageous because it maintains the effluent gases at a high temperature and so permits them to travel far before precipitation. The dilution of fume is proportioned to the square of the height of a chimney.

**H**ONOR to Mr. Gompers! The president of the American Federation of Labor has taken a stand the importance of which can be gauged by imagining him to have done the opposite. At this juncture the patriotism of the leader of organized labor means everything to the nation. We note that C. H. Moyer, president of the International Union of Mine, Mill, and Smelter Workers has taken the cue. No strikes are to be tolerated during the continuance of the War. The decision is of immense importance. It remains for all employers to recognize this patriotic action and to meet it in the same spirit. Such solidarity will assure our soldiers and sailors unfailing support in the completion of our great task.

**S**EVERAL industrial companies at Chicago have united to issue a circular stating their intention not to issue Christmas cards this year, but, instead, to set aside for the Red Cross or other relief organizations the money usually spent in this way. We commend this decision heartily. Both in business and in private life we ought to discontinue the sending of Christmas cards. This is no time for wasting time, money, or paper-pulp on such trifles. The same is true of the larger proportion of little presents, outside the family, that go into the discard within a few weeks after their arrival. Instead, let us restore the good old fashion of writing

letters, with some feeling for the amenities of the epistolary art. We must be soberly thoughtful this Christmas, realizing the national crisis and the world crisis, more particularly the suffering and destitution of millions whom it is our duty and privilege to help.

**T**HE premier goldfield of the world, the Witwatersrand, is feeling the pinch just like any small mining district anywhere else. We are informed that some of the poorer mines are likely to be shut-down in order to conserve supplies for those that are more productive. The scarcity of shipping has interfered with the importation of materials, so that a real difficulty exists in continuing the large-scale operations for which the Rand is famous. Old shoes and dies, together with other discards, are being utilized. Every bit of scrap-iron is being re-melted. At the Robinson this is being done by the Heroult method of electric smelting. Old boilers and compressors have become valuable, and have been rescued from the junk-pile. The electrification of the mine and mill plants caused a lot of machinery to be scrapped; this is now being used to good purpose. Thrift has become compulsory. The British government early in the War took steps to ensure a supply of cyanide, steel, and other necessities for the mines at Johannesburg, because the production of gold was a source of strength to the Empire. Now that the credit of the United States has been thrown on the side of the Allies, the gold from the mines is not so important and it might seem advisable to save shipping for the transport of men and food across the Atlantic. The cessation of gold mining in South Africa, however, is unthinkable because it would bring widespread destitution to the communities now dependent upon this industry not only in the Transvaal and Rhodesia directly but in other parts of South Africa indirectly.

**C**ANADIAN papers continue to attack Minerals Separation vigorously. On November 7 Mr. George Chapman met the Mine Managers Association of Cobalt at a special session and delivered an address in which he replied to the charge that his principals were pro-German. Apparently he was not successful, for the president of the Association, Mr. B. Neilly, stated that although his remarks were interesting they were not convincing, and that the managers "as a body were equally

sincere in their belief that Minerals Separation was German-controlled." This we learn from the 'Daly Nugget,' which, however, has not lost its head in the controversy, recognizing that no proof has been forthcoming that Minerals Separation is an enemy-alien. On the other hand, our contemporary raises proper objection to the attempt at a monopoly shown in the contract enforced upon its licensees by Minerals Separation, in which the latter calls upon its victims "to promptly communicate to the licensors [M. S.] every invention or discovery made or used by them which may be an improvement, modification, or addition to any of the inventions specified in the letters patent within this license or may be useful in carrying out any of the processes thereby protected or any addition thereto or modification thereof whether patentable or not which the said licensees may use or be or become possessed of." Truly, Minerals Separation is not Prussian, but some of its methods appear to have been learned at Potsdam.

OUR readers are aware that the price of paper has risen about 100% during the last two years. We refer to 'book-paper,' such as that on which this is printed. The publication of technical journals has been burdened by the increase of expenditure due to this cause and we have taken a keen interest therefore in the inquiry made by the Federal Trade Commission created by resolution of the United States Senate on September 7, 1916. This commission has issued a pamphlet detailing "the findings of fact, together with conclusions and recommendations with reference to the book-paper industry." The report can be summarized in a few words. It has been ascertained that "the advances in the prices of book-paper in 1916 were excessive and not justified either by the increase in cost or by the changes in conditions of supply and demand. The advance was brought about in part by the activities of the members and secretary of the bureau of statistics." This bureau is an association of manufacturers that combined to advance prices "without fear of competition." While ostensibly organized to compile statistical information, the bureau "has been devoted to encouraging members to increase their prices." In short, the book-paper manufacturers have used the exigencies of the War to establish a cinch and to conspire to make an excessive profit by combining in restraint of legitimate trade. The statement made by some of them that there was a shortage of 'bleach,' or chlorine, was not a verbal inexactitude; it was a plain lie, like some other statements made by them to cover their tracks. If more chlorine be needed, the way to get it is quite easy. Electro-chemists habitually complain of the difficulty experienced in disposing of the chlorine evolved as a by-product in many chemical processes. For example, chlorine is an obstacle to the development of the electrolytic manufacture of caustic soda on a large scale. In the States of California and Maine, to examine the American conditions no more closely, large quantities of hydro-electric power are available at the switchboard be-

tween peak-loads, and salt water is handy; yet the paper-makers put up the price of paper with a weak apology that chlorine cannot be obtained, and at the same time the Government is commandeering the output of the alkali-makers, causing a caustic-soda famine, while power is going to waste that could be used in the production of both commodities. The Commission recommends "as a war emergency measure that all print-paper mills and distributing agencies operate on Government account during the continuation of the War, and that the total product be pooled in the hands of a governmental agency so that it may be equitably distributed at a fair price based upon cost of production and a reasonable profit per ton." We would like to see action taken under the Sherman Act for the prosecution of this successful effort to break the law against unlawful conspiracy in restraint of trade. We mention this matter not only because it affects us but because it is an example of a large number of instances in which the War is being used to victimize the public. If a man does not fight for his country and if he does not subscribe to the national fund, at least let us see to it that he is not given an opportunity to make business depredations on the community under cover of the extraordinary conditions created by the War.

IN a recent issue we referred to the Anglo-American corporation that has been organized at Johannesburg, London, and New York to finance business in South Africa. Primarily the purpose is to provide capital for the exploitation of new leases adjacent to the properties controlled by the Consolidated Mines Selection Company, with which Messrs. Walter McDermott and W. L. Honnold, among others, are identified. The names of the New York directors suggest that the Morgan and Rockefeller groups are participating. This is true only indirectly, the American interest in the enterprise having been subscribed in the name of Mr. William B. Thompson, a gentleman that needs no endorsement from any other financial powers. We are informed that this group has made a successful tender for the south De Rietfontein lease, the north lease going to the Barnato Bros. The Transvaal government declined tenders made for two other leases, one of which, the west De Rietfontein, will be re-advertised shortly. The proportion of profit payable to the Government as royalty on the south De Rietfontein lease is 25%, whereas that payable on the Barnato tender will be nearly double, making the latter an unattractive scheme. The lease secured by the Anglo-American group, through the Mines Selection, will be incorporated later in the Springs Mines, which, with the Brakpan, constitutes part of the valuable property already controlled by this group through its Johannesburg and London affiliations. We understand that the Anglo-American Corporation may take part in financing a loan for the South African government. Whatever be the outcome of this new departure, it is most interesting as an evidence of American participation in the mining industry of the Rand.

## Thanksgiving

The President has called upon our people to observe next Thursday as our annual day of thanksgiving, and the Governor of the State has issued a similar proclamation. Indeed, there is much for which we may be thankful; to be alive to see the greatest events in human history; to be in a land safe from invasion at a time when ten countries are feeling the tread of an enemy; to have national wealth and prosperity when many nations are humiliated by poverty and failure; to have plenty of food when millions are going hungry; to be in the enjoyment of peaceful homes when thousands of hearths are smoking ruins; to be free when others have been enslaved by a savage conqueror; to be free when millions are prisoners in the hands of the enemy; to be confident of our freedom when other peoples are in fear of subjugation; to be able to fight for freedom for all the world as once before we fought for our own; to have the sinews of war, the material, and the machinery for making the weapons, munitions, and ships needed for successful war; for the gallant men that are able and willing to battle for our cause on land, on sea, and in the air; for the patriotic spirit that has united all parties, professions, and classes in a common endeavor; for all of these we are thankful, but most of all for the awakening of this nation to a purpose greater than material success, to the discovery of a soul, undismayed and unconquerable, that shall guide us through this dark hour to final victory and enduring peace.

## Recruiting Labor

On another page we publish a bitter protest, on the part of an engineer directing the work of a gold mine in Mariposa county, against the attempt to induce miners to leave their employment in California for the sake of the higher wages offered at a copper mine in Arizona. Our protestant even imputes a low code of professional ethics to the young engineer that has been recruiting in his neighborhood and also to the manager of the Inspiration mine. We happen to know all the persons concerned in the dispute. Mr. C. E. Mills, the manager of the Inspiration, has a reputation that will defend him better than anything we need to say, and his energetic representative, Mr. C. E. Arnold, will be pardoned if he fail to recognize the description of himself appearing in Mr. S. E. Rau-Roesler's letter. The question cannot be discussed on that plane; let us consider the fundamental point, as to whether it is fair to induce men to leave one company in order to work for another. Usually it is not done in the home district because such action causes ill feeling, and the managers of neighboring mines try to live on good terms with each other. It is extremely annoying to have your neighbor steal your cook, for example, and it is not done in the 'best society,' whatever that may mean. The amenities of neighborliness are transgressed by such a depredation. However, Mrs. Jones of Jonestown

would not hesitate to beguile the chef in the employ of Mrs. Smith of Smithtown, supposing that the ladies had not a bowing acquaintance. So Mr. Mills' representative thought it proper to invade Mariposa county and secure workmen for Miami, not thinking of the annoyance he might cause the manager whose preserve he would violate. It looks like a competition, not pleasant to the victim, but justified by the exigencies of business. Personally, we believe that miners on the Mother Lode might well hesitate to exchange the foothill country of California for the desolation, however picturesque, of Miami. No married man should be in a hurry to transplant his family from a garden to a desert. Moreover, we would like to ask Mr. Arnold how the cost of living compares? But a broader question arises, should the gold mines be depleted of their labor in order to stimulate the mining of copper. The idea obtains that this nation, being now engaged in war, needs copper more than gold. For the moment the stock of gold in the Federal Reserve banks is plethoric, but it is not a superfluity, for it will be needed to sustain the enormous credits that we are supplying our Allies for the furtherance of the War. Moreover, is it wise to injure the old settlements around the gold mines in order to invigorate the new camps about the copper mines? Certainly the State of California will resent any steps taken to injure its established industry for the sake of strengthening that of another State, even such a splendid member of the Union as Arizona. These are knotty problems. On the whole, we believe that there should be as little disturbance as possible of one industry for the sake of another, and that while recruiting for labor on the part of agents from Arizona is in no wise nefarious, it is objectionable.

## The Lady or the Tiger?

Villa's attack upon Ojinaga the other day, revives interest in Mexico. Under the strain of vital and catastrophic events in Europe, we have been inclined recently to ignore the country south of the Rio Grande. By preference we avoid slang, but it is inevitable, in this connection, that we should recall Villa's apt remark when the European storm broke in 1914, "the Kaiser's war will make mine look like thirty cents." It was true; the diversion of attention from "our pet bandit" made it more difficult for him to finance his operations, until the stock fell so low that he could not have sold the entire issue in the revolutionary market for the proverbial 'thirty cents.' The European war helped Carranza to establish himself because it also assisted President Wilson to pursue his chosen Mexican policy less hampered by adverse opinion. Lately the revolutionists have shown renewed strength, which is prejudicial to the interests of Mexico and in consequence to our own country. Political stability and advancing prosperity in Mexico have always been the sincere wish of the people of the United States, and at this time of international struggle it is more earnestly desired than ever. It may be amusing to pet bandits when no serious national enterprise is afoot,

but today we care nothing for the momentary enthusiasms of the time when we had leisure to view with interest the spectacular episodes of romantic Mexico. It was natural then to applaud first one and then another of the players as each scored in the game. Today we wish that Villa and Zapata and Carranza would form a truce and settle down to orderly living. Carranza might properly enough offer a sweeping amnesty, without any strings tied to it, as an inducement to 'bury the hatchet.' We are constrained to say that after the high-sounding verbiage of the decrees that were promulgated with this ostensible purpose has been stripped down to the inner fact, it is certain that no political opponent of the 'supreme government' in Mexico would find sufficient guarantee of safety to induce him to risk his life in the hands of his erstwhile enemy. That has been a fault of every faction that has risen to power; Madero committed it, and so did Huerta, and Carranza has done no better. The real balm that healed the wound at the end of our Civil War was the generous amnesty granted, so complete in its scope, and so unequivocal in its terms, and so dependable because it was an Act of Congress and not a decree by a political chief, that men could accept it and then forget the matter.

Venustiano Carranza just now has such an opportunity as seldom comes to any man in this world. In calling attention to it we may remind him that Porfirio Diaz also had the opportunity of a glorious immortality in the archives of the world, and he sacrificed it. Today he is remembered as a man of achievements; but his character is under discussion, and his personal weaknesses are brought forward for examination. He failed of being a Washington, against whom it is held a sacrilege to recall his human shortcomings. After being the master-builder of a devastated country Diaz should have crowned his work by stepping down, as did Washington, ready to help and counsel if need be, but eager to become a passenger in the ship of state, leaving another master on the bridge. On September 16, 1910, a host of friends of the valiant old Mexican Cid watched and waited for the great stroke that should give him a place among the immortals, but the advice of Ramón Corral and other sycophants robbed him of the proper fruit of his long and conscientious services to the country. Carranza is also at the parting of the ways. He may choose a seat of honor in the temple of history or one of ignominy and regret in the outer darkness that follows the sunset of his opportunity. It lies before Carranza to re-build the shattered fortunes of Mexico faster than Diaz ever dreamed of doing; if he should so elect, he could make himself first in the hearts of his countrymen, and be held in his presidential seat by the pressure of universal acclaim. In a single year he can do more for Mexico than Diaz did in thirty. The opportunity is to follow the lead of the great nations that have made common cause against the Teutonic scourge. By joining the allied nations he becomes one of us, a friend, a coadjutor, working in harmony with us, sharing what his people can offer, and welcome to all the financial and other help

that America and England and France can render. Financial and industrial relations in Mexico would then be equalized with the rest of the world, and her share of prosperity would grow great in proportion to the magnificence of her natural endowments. Mexico has all to gain by accepting the favor of the world. It would be as an industrial contributor, adding to the supplies of metals and foods and cordage that her participation would be most active, and she would grow enormously rich. This is the opportunity, the way to stifle revolution, to silence political foes, to bring back the exiles as friends ready to help in the upbuilding of the 'patria.'

There is something more to be said, however. In the first place, amnesty that is frank and conclusive must be granted; something far more frank than has yet been spread upon the statute-books of Mexico. Next, President Carranza must remember that the revolution was not meaningless; that it stood for two quite definite ideas, namely, agrarian reform and "Mexico for the Mexicans." Up to date no true agrarian reform has been achieved by Carranza, and it must be achieved if he is to become in any measurable degree a father to his people. It is a knotty and difficult problem; any man who knows the complicated antecedents of the situation as it existed in 1910 will admit that; but it is not insoluble; nor will the solution of it necessitate doing serious damage to the interests of the landed proprietors of record. Finally, the issue between the Mexican and the 'gringo' must be met, and that is a much simpler matter than agrarian reform. We believe heartily and completely in the doctrine "America for the Americans;" our Congress and our State legislatures have long expressed the national feeling, sometimes a bit peevishly by restrictions upon land tenure, but these usually have been erased from the statute-books by adverse court decisions. The thing, however, that our lawmakers have not done was to grant monopolistic concessions and to peddle them among foreigners. We venture to suggest to President Carranza that while his onslaught upon the concessions of the old regime may have lacked something of strict legality, it was to be expected as a logical result of the revolution, with possibility of the ultimate compensation that ever crowds on the heels of confiscation; but his own hand is becoming free with these iniquitous dispensations, on which no secure economic life can be established. By nature a concession is obnoxious to the people; it is provocative of unrest and revolution. It is, at best, a crude instrument for promoting investment and for inviting foreign capital. The United States has been a favorite field for foreign enterprise, and such participation has accelerated the growth of the nation without threatening either the industrial or political rights of the people. The foreigner has come and helped us to develop America for the Americans, just as he will help develop Mexico for the Mexicans if the rulers pursue sound policies in legislation and in administration of the laws. Carranza is in the arena with the world looking on; he must open one door or the other; one leads to the tiger's cell; and the other to ....?

## Recruiting Labor From the Gold Mines

The Editor:

Sir—Your articles on methods employed at the Inspiration mine have proved of much interest to me, and I am sure that all the members of the profession appreciate them. I also beg to draw attention to methods employed by the Inspiration, and especially by members of the engineering corps of that company, which have occasioned some remark and would seem to denote a considerable lowering of the ethical bars presumably observed by members of the profession elsewhere.

It is a matter of record that the pay of miners on the Mother Lode is at present considerably below that paid on the copper scale at Miami. It is also a matter of record that there is at present great unrest and considerable dissatisfaction among miners all over the country. There is an unquestionable shortage among operating mines of men suitable to do the work. The Mother Lode has been fortunate in most instances because there is a distinct class of men who have always followed gold mining, who know the Mother Lode conditions thoroughly, and who have been in consequence fixtures on the Lode. Generally they have been dependable, though they have grown exacting in some ways. It is not going too far to say that these men were satisfied with their wages, their working conditions, and their surroundings.

The Inspiration has barred the I. W. W. agitators, after a rather disastrous experience. The Inspiration, however, does not hesitate to send their own peculiar brand of I. W. W. agitators to the Mother Lode, to coax men from our already-undermanned properties, with promises of higher wages, to make them dissatisfied with conditions on the Lode, and generally to spread the gospel of discontent.

Unfortunately, and this is the reason why I draw your attention to the matter, the man in charge of the agitation is C. E. Arnold, consulting engineer. We, on the Lode, going our own way in happy content, had no idea that the profession was honored by members of this un-American crew. It would as soon occur to us to turn agitator and body-snatcher as it would occur to us to go to Miami to disturb adjusted working conditions among the men there. However, I am credibly informed that inducements with regard to wages were made to certain of the men employed at my mine, that their fare was posted with the railroad, and that letters were sent them by Mr. Arnold urging them to go to Miami. Remember that these men were and are employed, have had no occasion to be discontented, and are given the best of food

and living conditions in a climate almost too ideal for mining.

Either Mr. Arnold is not aware of the fact that there are certain things an engineer cannot prostitute himself to undertake, or his pretensions of belonging to the profession are without fact, or the price offered by the Inspiration for miners was too great an inducement for his small ethics to withstand. At any rate, even the best interpretation of his actions does not reflect credit on himself, on the Inspiration in particular, and on the profession in general.

This protest, I believe, is directly in line with your exposition of Inspiration methods, and also I think conforms to the better standards among the men of the profession that your paper stands for.

S. E. RAU-ROESLER.

Bagby, California, November 8.

[We discuss this subject on the editorial page.]

## King of Arizona Company

In our issue of November 10 we published a letter from Colonel Epes Randolph taking exception to a reference made to him in our interview with Mr. D. M. Riordan, appearing in the issue of October 6. When publishing Colonel Randolph's letter we omitted the concluding paragraph, which read as follows:

"It is my wish that you publish this letter in the next issue of the MINING AND SCIENTIFIC PRESS, giving it the same prominence that you gave to the libelous Riordan interview. Also I request that you wire me upon receipt of this letter, at my expense, whether or not you will comply with this request."

We replied in the affirmative and published his letter, minus this paragraph. Colonel Randolph insists that this paragraph should not have been omitted; we demur, but we publish it now rather than prolong the controversy. The paragraph was omitted because it formed no part of his statement; it was clearly in the way of an instruction. Of course, the term 'libelous' is one that we cannot accept. If Colonel Randolph's feelings were hurt by anything said in the interview, we regret it; so does Mr. Riordan, who states that he had no more feeling of animosity in his mind when he was answering my questions than if he were to say that the Oaks would 'do up' the Seals, or that Yale would 'do up' Harvard. He says that he felt at the time, 18 years ago, that undue rigor was being manifested in expressions to him in regard to Smith and they conveyed to his mind a sense of

severity that he did not feel was quite deserved. That was all.

Further he says: "The quotations from the minutes of the meetings of the board of directors of the King of Arizona are no doubt correct. I have no means at hand of verifying them. But in our meetings, as in all the meetings of boards of directors in which I have taken part, there is a great deal of discussion that is never spread on the minutes. Things are said back and forth that are not made a part of the permanent record. At the time I was talking to you I was trying to crowd into the insistent activities of a busy day such answers to your questions as came into my mind on the spur of the moment, and with no thought of unkindness toward any human being. I think if Messrs. Smith, Blaisdell, and Ives could be got together in a room, some, or all of them, would verify the substantial correctness of the picture I was trying to present of *my* activities, which, as you know, I was reluctant to have published at all, because I did not believe there was anything in my recollections that could be of particular interest. I think Colonel Randolph is taking this matter entirely too seriously, and I am sorry that he has done so.

"With reference to my remark about 'real money,' to which Colonel Randolph objects, it seems singular to me that the company records would not 'show how much money Mr. Smith spent on his contract,' but at the time I invested my money I had it not only from Mr. Ives, but, I believe, from Messrs. Blaisdell and Eichelberger that Colonel Randolph had put only 'a little money' into the venture, and had given his notes for the balance. This I am stating off-hand, from recollection, and am willing to stand corrected if I am in error as to what was then stated to me. But I am now prepared to accept Colonel Randolph's statement that he invested \$10,000 in real money on the day the mine was optioned; and if \$10,000 is, in his estimation 'only a little,' I congratulate him; \$10,000 looked to me like a very respectable sum of money then, and I have a good deal of respect for that amount today; even when many people talk as glibly about billions of dollars as if it were a wheelbarrow load of potatoes. But I certainly did have it verbally from Messrs. Randolph, Ives, and Blaisdell that Mr. Smith had put a considerable amount of money into the venture, or had pledged himself to do so, and at the time they spoke of this to me they were looking to Mr. Smith as the principal person who was putting in 'real money,' at that time, and was expected to continue doing so.

"If I have injured Colonel Randolph, or anybody else, in mind, body, or estate, I would (if need be) walk from here to Tucson and back again to make due, full, and satisfactory reparation. In trying to give you a composite picture fished out of the dusty pigeon-holes of a more or less battered old memory, I chatted away conversationally as I would if we were riding together on a buckboard across the desert, or climbing on horseback some mountain-trail. It was the merest recital, entirely devoid of malice or animosity. Colonel Randolph, at the time I first met him, had a high reputation as an en-

gineer, and all I have known of him since confirms this estimate of his professional equipment and his achievements. His plan to utilize the waters of the Colorado in the Grand Cañon was a splendid one, and should be, and I believe will be, some day put into practical service. His subsequent plan, carried through to a successful conclusion, to control the waters of the Colorado, after the Government engineers had failed to do so, should, and, I believe, will stand as an enduring monument to his resourcefulness and daring. So that all my predilections were in favor of avoiding the saying of objectionable things about him, or anybody. I think if Colonel Randolph were present in the room when you were questioning, and heard my answers just as I gave them, he would have been inclined to treat them in the good-natured way I did, and laugh at them instead of taking umbrage."

This closes the controversy.—EDITOR.

## Feeding the Mexicans

The Editor:

Sir—Your suggestion regarding the distribution of food to the starving peons in Mexico is, I believe, entirely correct. The same conditions existed in Nicaragua after the long campaign resulting in the overthrow of President Zelaya. The neglect of agricultural work during the revolution and a series of crop failures had resulted in a severe scarcity of food. This was being relieved by importation of corn, beans, flour, etc., from the United States, Salvador, and other countries. The short-lived Mena revolution, by cutting off these supplies, left the people in a state of destitution. When the revolt was ended by the intervention of the United States, the two thousand American marines and blue-jackets with their officers took over the civil administration of the municipalities, established law and order, and organized the distribution of food to the native population. In spite of their natural antipathy to the 'gringo', heightened by his interference in their internal affairs, the natives were compelled to admire and respect the honest and efficient administration of our soldiers.

Such a distribution of food in Mexico would do much to establish in the mind of the peon the idea that we wish him well, and that, rather than wishing to engage in a war of conquest, we are sincerely desirous of making the world safe for democracy.

J. A. PARKER.

Mina, Nevada, November 12.

NICKEL is in great demand for Germany, especially for making tubes for torpedoes. It is evident that she had not taken precautions to obtain a sufficient store of this metal, as she did in regard to copper, zinc, tungsten, and some others. It is now reported that the Christiania nickel works are to resume operations, under a contract to supply Germany with 100 tons of nickel per month. Exportations of nickel from Norway to Germany had been suspended for a considerable time.

# Heap-Leaching of Copper-Sulphide Ore

By COURTENAY DE KALB

Large-scale leaching-tests have been conducted for a period of nearly eight months at the Copper Queen mines at Bisbee, Arizona, following work for three years in precipitating copper with scrap-iron, in preparation

process has demonstrated a recovery of 80% of the copper in the ore, at a cost of 20c. per ton for transporting the ore from the mine to the leach-yard, building of the heap, and disposing of the tailing; 20c. for leaching; and 60c. for precipitation, including labor, power, maintenance, and the cost of iron consumed, charging current rates for the scrap-metal. The ore treated in the experimental heaps has averaged 1.25% copper, yielding 20 lb. cement-copper per ton of ore. The cement is obtained as an unusually high-grade product, assaying 60% copper. The cost of the whole operation, therefore, is only 5c. per pound of copper recovered. To obtain the total cost of the copper there must be added the cost of mining, shipping of the cement-copper to the refinery, melting, poling, and casting.

It will be seen that the precipitation is the most expensive step in

COPPER PRECIPITATING-PLANT, BISBEE

for handling the disseminated sulphide ore recently developed in Sacramento hill. The orebody, as tested by drilling, and further confirmed by underground exploration, has shown a large tonnage, some of which is of a grade suitable for smelting without previous concentration. The larger volume, however, with a tenor averaging about  $1\frac{1}{2}\%$  copper, will be treated by flotation. In addition, large tonnages that assay no higher than 0.9 to 1% copper will be available. This lower-grade ore will be leached, and it is proposed to treat it in heaps, taking advantage of the reactions that occur through oxidation when the mass is treated with the requisite amount of water. The principle, of course, is the same as that long utilized at the Rio Tinto mines in Spain, but the details whereby the system is made adaptable to American conditions have been evolved by Joseph Irving, who is in charge of the operations at Bisbee. The novel features introduced into the process are found chiefly in the precipitation, which will be considered first. As now conducted, taking into account the existing costs of supplies and labor, the entire

PRECIPITATING-VATS AND LAUNDERS

the process. When applied on a larger scale this cost will be reduced, of course, and improvements are even now being made that will effect further economy. At the present time an average of about 400,000 gal. of solution is passed through the precipitation-vats daily. Only 70,000 gal. of this comes from the leach-yard; the remaining 330,000 gal. consists of water from the Czar shaft, which contains about 63 grains of

copper per gallon. The experiments in precipitation were conducted on the mine-water for a period of nearly three years before 'heap-leaching' was tried. The possibility of economically reducing the ferric to ferrous salts by the use of Mr. Irving's pyrite filter was thus proved, and this paved the way for successfully treating the low-grade sulphides developed by drilling the disseminated granite-porphry ore on Sacramento hill. As a preliminary to the precipitation of the copper from the mine-water it is essential to eliminate the solids carried in suspension. The larger portion of the solid matter is removed by diverting the water through shunt-tanks where the checking of the current causes it to settle. Most of what remains is then caught in the pyrite filter.

The arrangement of the shunt-tank is illustrated in the accompanying sketch (Fig. 1), where *F* is the flume carrying the mine-water, *S* the diversion-launders, with a gate *G*, which may be changed so as to close either the flume *F*, or the diversion-launders *S*. *T* is the tank, 32 ft. long, 8 ft. wide, and 6 ft. deep. The tank is provided with a discharge-door, *D*, near the bottom, for flushing out the accumulated sediment. About 400 cu. ft. of sludge is settled from the mine-water in three months, and it assays from 0.3 to 1% copper.

**FILTRATION AND REDUCTION.** After the coarser material has been settled the waters are conducted to the filtration-vats at the head of the precipitating-plant. As originally designed it was intended to use six vats, in each of which would be placed approximately 40 to 45 tons of pyritic ore to serve as a filter. The vats are round and are made of 3-in. redwood. As now constructed, the solutions are caused to flow downward through vertical box-pipes at the side, and then to pass upward through the filter-bed, discharging at the opposite edge of the vat into a 2 ft. by 10-in. launder. The filter is composed of pyritic ore, from  $\frac{1}{2}$  to 1 in. diameter, with some fine material, assaying about 2% copper. The bed is  $2\frac{1}{2}$  to 3 ft. deep, and is supported upon a wooden grating resting on 4 by 6-in. beams. The solution flows through each filtration-vat at the rate of 100 gal. per minute, and the filter retains 75% of the solid matter still in suspension. In addition, the pyrite converts the ferric salts in the solution into ferrous salts, thereby saving iron in the subsequent precipitation. It does more than this; the rapid corrosion of iron in the precipitation-tanks when ferric salts are abundant would add to the amount of corroded iron-scale, which becomes detached and accumulates in the cement-copper. It also provides acid which maintains a 'sweet' condition of liquor in the precipitating-tanks, and prevents settling of basic iron salts, thereby improving the recovery. An indication of the influence of the pyrite filter in accomplishing the reduction of the ferric salts is shown by the fact that after introducing the filter the grade of the precipitate recovered was raised from less than 40% to an average of 60% copper. Economies follow from such a change in assay-value, not only in the handling, drying, sacking, and shipment, but in the subsequent melting at the refinery.

Each filtration-vat is provided with a large door on the level of the filter-bed, through which the accumulated sediment may be flushed at intervals; it is also used for discharging the spent filter. The mud is washed out once a month. If allowed to collect for too long a time the particles of pyrite become coated with slime and the chemical action of the filter ceases. It is also desirable at intervals to turn the material that constitutes the filter-bed in order to expose fresh surfaces to the action of the solutions. Mr. Irving is now preparing to modify the arrangement of the ore-filter by raising the tank, using a 3-ft. filter-bed of screened pyritic ore and filtering downward. This will permit a percolation of 500 gal. per minute. The filtered solution will flow by a siphon from the lower part of the vat to the top of a precipitating-vat set two feet lower. The sediment caught in the filter will be flushed from time to time without removing the ore-bed. The action of the pyritic filter is represented by the following equation:

Although this explains what takes place, and is in accord with the deposition of elemental sulphur in nature, as often found in pyrite casts resulting from such a reaction, the reducing effect of the filter is undoubtedly more complicated than the above equation would indicate. The promptness of the reaction is the interesting feature of Mr. Irving's application of the pyrite filter. Nishihara\* has shown that many common minerals yield a relatively prompt reduction of tenth-normal ferric sulphate. For example, he obtained a sharper and more immediate effect with kaolinite than with pyrite, although after more prolonged contact the larger reducing effect was obtained with an equal weight of pyrite. Pyrrhotite was far more active, the reduction, expressed in terms of cubic centimetres of  $\text{KMnO}_4$  used in titration, being four times greater than for pyrite. The various common ferro-magnesian silicates found in the gangue of many ores also exert a not inconsiderable reducing power. Chalcopyrite likewise displays a reducing action, and, as might be expected, marcasite is more pronounced in its effect than pyrite. Moreover, the reaction in all cases becomes more energetic when copper sulphate is present in the solution, and this is the case in the solutions derived from copper mines and from the heap-leaching of copper ores. It should be considered, also, that the pyritic ores from different mines, and perhaps from different parts of the same mine, would be expected to show important variations in reducing power, since refined analysis proves that pyrite rarely, if ever, corresponds to the formula  $\text{FeS}_2$ ; it is a somewhat indeterminate solid solution of  $\text{FeS}$  in  $\text{FeS}_2$ . The effect of this on the ability of pyrite to reduce ferric sulphate in waters coming in contact with it, is to be taken into account, and upon this probably depends the continued action of the filter, which must represent a

\*'Economic Geology,' Vol. IX, pp. 743-757.

PLAN AND SECTION COPPER PRECIPITATING-PLANT, COPPER  
QUEEN MINE, BISBEE, ARIZONA

penetration and breaking down of the pyrite particles rather than a mere superficial reaction.

Another feature in the economic use of pyrite as a reducing filter in the preparation of copper-bearing solutions for precipitation is the fact that the filter itself gradually becomes depleted of its copper. Ferric sulphate reacts with either cupric or cuprous sulphides, reducing the iron salt to the 'ous' state and yielding, respectively, copper sulphate, and copper sulphate plus cupric sulphide. The mine-water at the Copper Queen gives an extraction of 50% of the copper in the filter in five months, lowered from the original assay of 2.02% to 0.6% in the discarded filter-bed, and at the end of a year the filter has become too inactive to yield economic results. The mine-water varies materially in its load of metallic salts at different times of the year, depending on the rainfall. A typical analysis shows about 21 grains of copper per gallon, equivalent to 0.04%, about the same quantity of ferrous iron, and approximately 16 grains of ferric iron, or 0.03%. The amount of copper in the dry season often increases to double the above quantity. A fair example of the composition of the solutions entering the reduction-vats and of the outflow to the precipitation-plant is given below:

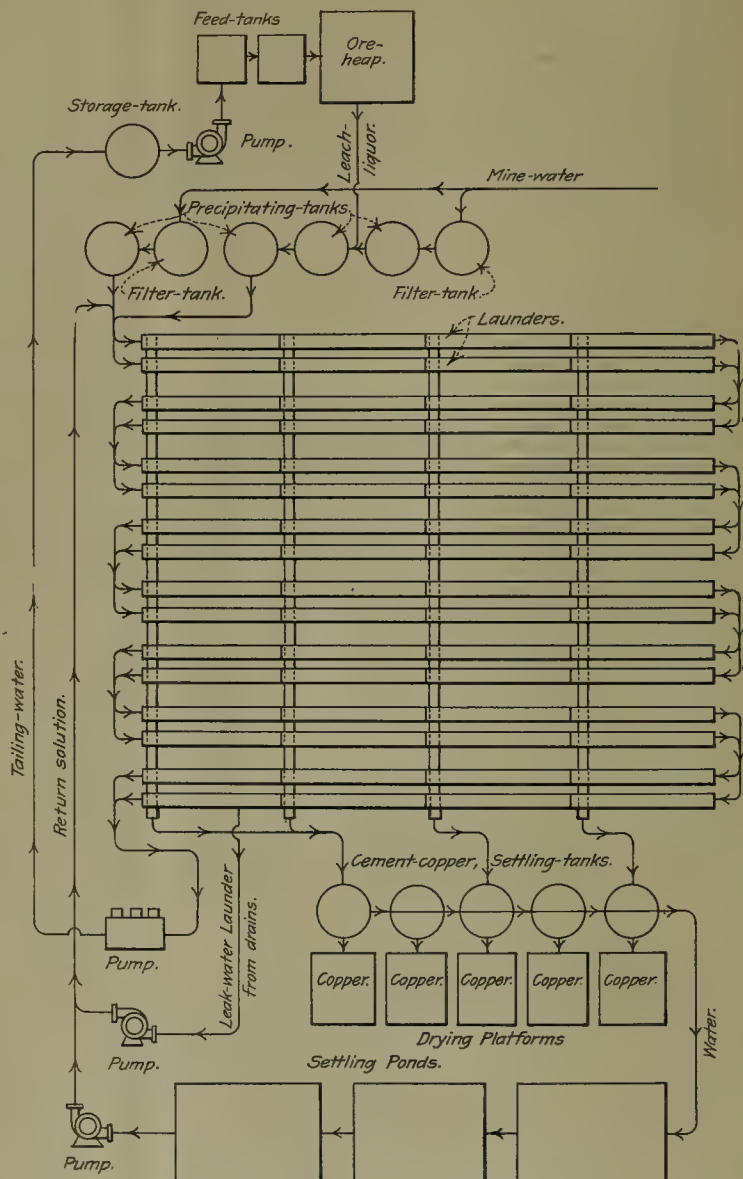

REDUCING EFFECT OF PYRITE FILTER ON SOLUTIONS

	Copper	Ferrous iron Grains per gallon	Ferric iron Grains per gallon	Free H <sub>2</sub> SO <sub>4</sub>
Entering vat.....	20.98	13.32	15.66	6.00
Leaving vat.....	39.64	25.10	1.74	20.00

The solutions represented by the foregoing analyses consist of mine-water only, and the reduction shown is the average at the present time.

**PRECIPITATION.** The clarified and reduced liquors after filtration are conducted to the precipitation-vats, of which four are now in service. These are of the same size as the two vats that contain the pyrite filters, namely, 20 ft. diam. by 10 ft. deep. They are similarly fitted with false bottoms to support the scrap-iron employed for precipitation. By the present arrangement only the mine-water passes through the filters, since the leach-liquor from the ore-heap has been subjected to the same action in the process of leaching through the pyritic ore. The liquor from one filter-vat passes through only one precipitation-vat, and the overflow thence goes to a cascade of precipitation-launders below. The mine-waters going to the second filter-vat overflow to another precipitation-vat, and the outgoing liquor unites with the

leach-liquors from the ore-heap, and thence goes through two more precipitation-vats placed in series, the final overflow being then delivered to the head of the system of precipitation-launders. The course of the solutions may be more readily traced by means of the accompanying flow-sheet.

SOLUTION FLOW-SHEET

Better precipitation is obtained in the vats than in the launders, and this fact will lead to some important modifications of the system when carried into effect on a larger scale after the Sacramento Hill mine begins to deliver a heavy tonnage of ore to the leach-yard. It is found that a single vat of the size now used will extract on an average 40% of the total copper-content from the solution when flowing at the rate of 100 gal. per minute

and carrying 10 lb. copper per 1000 gal. The iron in the large round vats consists of cumbersome scrap from the mine and smelter, such as old cars, pumps, compressor parts, worn-out converter-shells, old flues, and the like. The solution is conducted through a down-take to the

tation-launders, consisting of eight pairs, are set parallel to the line of upper round vats. The launders in each pair are on the same level, and cascade into the next pair below. Except when cleaning up, the stream of solution is divided between the two launders in each

FIG. 1. SETTLING-BOX FOR MINE-WATER

bottom of the vat, and flows upward through the false bottom and the scrap-iron. The cement-copper is washed down through the false bottom with tailing-water from the precipitation-plant, and is discharged into launders underneath that carry it to settling-tanks below. The

FIG. 2. PLAN FOR BURRO MOUNTAIN LEACHING-PLANT

pair. The process of cleaning up is continuous, so that one launder in the system is always cut out, and during this process its neighbor carries the full stream. The

FIG. 3. DORR MECHANISM FOR PRECIPITATION-VAT

tailing-water, as will be more fully explained later, is pumped to the ore-heap above, and the main through which these spent liquors is pumped is so placed that branch-pipes may be utilized for drawing off what water is required for washing the cement-copper from either the precipitating-vats or the launders.

Consulting the plan it will be seen that the precipi-

FIG. 4. SECTION ON PRECIPITATION-LAUDERS

launders are each 250 ft. long and 4 by 4 ft. in cross-section, divided into four compartments. There is a narrow downtake at the head of each compartment to deliver the solution at the bottom. Smaller sizes of scrap-iron are used in the launders, resting on a false bottom made of slats, 4 in. wide and set 2 in. apart. This false bottom gives 6-in. clearance to admit of thor-

oughly hosing out the cement-copper. The copper is discharged into launders underneath that take it to the settling-tanks and ponds. The tailing-water used in the clean-up is taken from 2-in. bronze pipes connected to the large main leading from the pumps to the leach-yard. All the launders are built of 2-in. Oregon pine and the bents and bracing that support them are of the same material. Considering the weight carried the construction seems light, 4 by 6-in. posts being used in the bents, and 2 by 4-in. material for bracing. The leakage is small, but some solution unavoidably escapes, and this is preservative against decay, although the cellulose suffers chemical changes that leave the wood soft, and with greatly lessened transverse strength. No trouble, however, has been experienced by collapse, and the structure has stood with very little repair and no renewals for three years. This is interesting, because in addition to the dead load there are vibrations from moderately heavy traffic in running trucks loaded with iron for filling the launders. A tramway is provided between each pair of launders; it is so arranged that the truck can be run off at any level from a platform-car operated by cables on an inclined track extending from the scrap-pile at the railroad siding below to the upper round vats, following the grade of the system of precipitation-launders.

On the ground underneath the precipitation-plant ditches serve to drain escaping solutions to launders that lead to a lead-lined Buffalo centrifugal pump with a 2-in. discharge, which returns the leak-water to the precipitating-system. The cement-copper is delivered by launders placed at right angles to the precipitation-launders, into a series of five circular redwood settling-tanks, discharging one into another, the inflowing stream being delivered at the centre, and the outflow over the periphery falling into surrounding circular launders. The settling is fairly complete, and the thickened product is flushed from the round tanks into large square shallow drying-vats where it evaporates in the Arizonan sun. The dried cement has a lustrous red color, and assays 60% metal. The overflow from the tanks is further settled by circulating through a series of three ponds, the collected sludge assaying from 10% copper in the first pond to 5% or less in the last. All this cement copper is shipped to the smelter at Douglas. The clarified liquor from the final settling-pond is called 'tailing-water.' It contains an insignificant amount of copper, which, however, would involve an appreciable loss if allowed to go to waste. The tailing-water has the following composition:

Copper	Ferrous iron	Ferric iron	Free H <sub>2</sub> SO <sub>4</sub>
Gr. per gal.	Gr. per gal.	Gr. per gal.	Gr. per gal.
2.32	150.80	26.68	3.48

The tailing-water is pumped to the feed-tanks above the leach-yard, and is used for wetting the ore-heap, thus returning, enriched in copper, to the precipitation-system. It is handled by a geared 3-piston bronze Aldrich pump, driven by a 20-hp. Allis-Chalmers motor taking current at 220 volts. The quantity of solution is 300 gal.

per minute, delivered against a head of 100 ft. The main that carries the returned tailing-water is an 8-in. Crane wood-lined pipe. The leak-liquor, which is returned to the head of the precipitation-system by lead-lined centrifugal pumps, is carried in a 3-in. cement-lined pipe. The cement lining is about  $\frac{1}{8}$  in. thick, and the coating is done at the Copper Queen shop at Bisbee. The entire operation of the plant, consisting of filtration, precipitation, cleaning, handling scrap-iron, drying and sacking cement-copper, pumping, and general maintenance, requires a force of eight men and one foreman. The iron consumed amounts to  $1\frac{1}{2}$  lb. per pound of copper precipitated. The theoretic quantity required is 0.88 lb. iron for each pound of copper, but there is a mechanical loss, and a certain amount of ferric sulphate still remains in the solution after passing through the pyrite filter. Every unit of ferric iron calls for half as much metallic iron in its conversion to ferrous sulphate in the precipitation-boxes. The free sulphuric acid also consumes iron. Therefore the recovery of one pound of copper with an excess of only 0.62 lb. of iron over the theoretical requirements, in which is included the mechanical loss as well as the loss from free sulphuric acid in the solutions, shows how important a rôle is performed by the pyrite filter when it is considered that the original mine-water carries nearly pound for pound of copper and ferric iron. Without the pyrite filter this ferric iron alone would dissolve a half pound of metallic iron for each pound present as a ferric salt in the solution.

It has been pointed out that the precipitation in large round vats has been shown to be more efficient than in launders. In the new plant that will be built to handle the solutions from heap-leaching on a large scale when treating the Sacramento Hill low-grade ore, such vats will entirely supersede the launder-system. The same system may be installed at the Burro Mountain mine, the tentative plan being shown in outline in the accompanying sketch (Fig. 2). A further improvement is proposed, in accordance with a design by Joseph Irving, Jr., which consists in adapting the Dorr mechanism to a precipitating-vat. As will be seen in Fig. 3, the stirrer is placed below the false bottom, and the solution is fed through a vertical wooden conduit surrounding the spindle of the machine, which may be a solid or a perforated cylinder. The stirrer serves to impart a movement to the solution, causing the copper, as fast as it is reduced by the scrap-iron resting on the false bottom, to become detached. As the cement-copper settles it is swept to a pocket in the bottom of the tank, from which it can be drawn off at intervals.

**HEAP-LEACHING.** The ordinary reactions in the oxidation of sulphides of iron and copper have long been utilized as a ready means for leaching low-grade ores in which the copper is present either wholly as a sulphide or as a mixture of sulphide and oxide. Although the last word has not been written on the subject, the principles are quite well understood; nevertheless, the application of heap-leaching has led to frequent disappoint-

ment, partly because of the difficulties arising from ferric sulphate in the solutions, and from lack of familiarity with the details of management in leaching ore-heaps. Therefore the work done at Bisbee is of great interest, since it has established an economic line of treatment that will be employed both at the Burro Mountain mine in New Mexico and at Bisbee on a larger scale. Indeed, the possibility of adapting the method as a means for profitably extracting the copper from the 1,500,000 tons of the lower-grade ore developed in Sacramento hill has been an important factor in the plans for beneficiating that unique deposit.

It may be desirable to re-state the reactions responsible for the solution of copper in moistened ore-heaps, and to point out that no inconsiderable merit in the system lies in the possibility of recovering much of the copper that may happen to be present as an oxide. The very low-grade copper-sulphide bodies usually are found in fairly well-defined zones, either on the borders of higher concentrations of such ores, or on zones through disseminated

into the oxide. Carbonates of copper, however, are practically absent. The reactions on which the solution of the oxide depends may be represented by the action of cupric sulphate upon cupric oxide, yielding basic

TOP OF ORE-HEAP, SHOWING TERRACES AND BASINS

copper sulphate, thus:

Acid generated in the oxidation of the sulphides will also directly attack both cuprous and cupric oxides, as follows:

On the other hand, there is danger of reducing cuprous oxide to metallic copper in the presence of ferrous sulphate and free acid:

This tendency, however, should be offset by the solubility of freshly precipitated copper in dilute acid and in ferric-sulphate solutions at the temperature present and with the time available in a slowly oxidizing ore-heap, according to the reactions:

The reaction yielding the cuprous sulphate found in Nature as the mineral dolerophanite may also take place between cupric sulphate and cupric oxide:

It should be pointed out that the danger of producing metallic copper is always considerable, and deserves attention on the part of the superintendent with a view to obviating as far as possible the conditions favorable for such reactions. Metallic copper may result also from the action of ferric sulphate upon cuprous sulphide, as seen below:

Mr. Irving admits the possible formation of some

BUILDING ORE-HEAP FOR LEACHING

nated orebodies where oxidation has been more rapid than the reactions that determine enrichment. These two cases are found in Sacramento hill, and in each of them a portion of the copper has been converted

metallic copper in the leaching of the ore-heap, but it has not been definitely ascertained what proportion of the copper in the leach-tailing, which contains about 20% of the original copper, is in the form of metallics. It would be an interesting inquiry, since it is difficult to believe that any considerable amount of sulphide could escape the action of the solutions after a year of treatment under conditions carefully maintained to secure the highest possible degree of oxidation.

The following equations are offered by Mr. Irving as representative of the reactions that take place in the ore-heap. The first stages are those that produce the active reagents, namely:

The function of the ferrous sulphate and sulphuric acid has already been discussed. The ferric sulphate is the compound that attacks the copper sulphides, and when a proper balance exists the ferric sulphate should be wholly reduced to the 'ous' state; furthermore, the effect of the pyrite in reducing the ferric salt is operative as explained in connection with the pyrite filter. Accordingly a well-managed heap should yield leach-liquor comparatively free from ferric sulphate, thus rendering precipitation on scrap-iron economical. To effect this desirable result the heap would have to be rich in pyrite. The further reactions on which the leaching of the copper sulphide depends are the following:

The latter reaction is probably more generally accomplished in the presence of abundant oxygen without the liberation of elemental sulphur, as expressed in the equation:

In making ready to build the heap a site was chosen in an arroyo or gulch on the side of Sacramento hill, out of the way of flood-waters. No special preparation of the ground was attempted; the space was merely well-covered with wash from the hill, and the slope was about 8°. The heap was built of run-of-mine ore from the Sacramento Hill deposit, and contained 9487 dry tons, the largest lumps being 10 in. diam. The upper surface of the heap has an area of 12,000 sq. ft., the vertical depth at the lower edge is 25 ft., and at the upper edge it is 5 ft. A vertical depth greater than 25 ft. is inadmissible, owing to the danger of channeling. A gradual and uniform subsidence of the leach-water is of prime importance. The top of the heap has two levels or terraces, in order to facilitate inspection so as to obtain information regarding the percolation. The difference of elevation between the two terraces is 4 ft. Each terrace is subdivided into basins 15 ft. square, separated by ridges of ore about 12 in. high. The basins,

furthermore, are so arranged that the fresh leach-water will overflow from one to another.

On first flooding the heap it absorbed 360,000 gal. of water, or 38 gal. per ton. The solution exudes from all sides of the heap until the surface becomes sealed by a crust of basic salts. After a little time the heap swells, and in places may burst out and then must be repaired by building bulkheads of the larger blocks of ore. The floors of the basins also become clogged by a deposit of basic iron salts, which checks the filtration. When this occurs they are dug up, and material from below is brought to the surface and again leveled preparatory to a resumption of leaching. One laborer on each shift is required. He serves as heap-tender, looks after the measuring or feed-tank, which supplies the leach-water, and takes care of a centrifugal pump that throws the water from a storage-tank to the feed-tank. As previously explained, the tailing-water from the precipitation-plant is elevated by an Aldrich pump, through an 8-in. wood-lined main, to be used for leaching the ore-heap. It is delivered direct to the measuring-tank, which has accumulators and an automatic tripper for discharging a volume of 450 gal. every five minutes. The average delivery of leach-water to the heap is 70,000 gal. per day of 24 hours. The amount varies somewhat, depending upon observed conditions of percolation and outflow, and is regulated by the superintendent and by the heap-tender. The rate of delivery of leach-liquor from the foot of the heap may not correspond exactly to the rate at which the fresh water is added, but the weekly averages will nearly balance each other. As an example of these discrepancies, on three successive days the following quantities of feed and outflow were observed:

	PERCOLATION	
	Feed-water to ore-heap	Leach-liquor outflow
	Gal.	Gal.
(a) .....	29,580	38,800
(b) .....	27,000	31,000
(c) .....	30,000	23,000
Total .....	86,580	92,800

Accurate samples of feed-water and leach-liquor are taken daily and assayed. The subjoined table gives representative analyses of the feed-water and the corresponding leach-liquors, in a series of four days.

	SOLUTIONS TO AND FROM ORE-HEAP					
	Pounds per 1000 gal.					
	Copper		Ferrous iron		Ferric iron	
	Feed-water	Leach-liquor	Feed-water	Leach-liquor	Feed-water	Leach-liquor
1 .....	0.20	5.18	0.33	0.66	0.33	0.50
2 .....	0.44	8.82	0.33	0.33	0.50	1.00
3 .....	0.44	7.01	0.33	10.44	0.50	1.82
4 .....	0.20	7.00	15.33	9.83	1.00	2.00

The last line in the table represents the present reactions with special reference to the formation of ferrous and ferric iron, and indicates a desirable result.

The speed of percolation is about  $\frac{3}{4}$  ft. per hour, so that the solutions take approximately 20 hours to pass through the ore-heap. The rate of extraction is calcu-

lated from the daily volume of solution and its assay. The average of the samples of ore taken daily while building the ore-heap gave the following result:

	%
Copper .....	1.3
Silica .....	60.7
Iron .....	10.5
Lime (CaO) .....	1.2
Alumina .....	12.1
Sulphur .....	9.9
Silver .....	0.12 oz.
Gold .....	none

Thus the total copper in the heap amounted to 246,662 lb., and in a period of five months 25% of the total copper has been extracted. Taking the recovery from the solutions in precipitation at 96%, this means an actual recovery of 59,198 lb. of copper, or nearly 400 lb. per diem. The cost of transporting the ore to the leach-yard and building the heap was 10c. per ton, and the average cost for leaching has been \$10 per day. It is possible that it may require two years to complete the leaching, giving an extraction of about 80% of the original copper, or approximately 189,435 lb. recovered as cement-copper.

Applying the reactions which occur in the direct leaching of ores in heaps, it has been proposed by Mr. Irving to crush copper ores for flotation in a solution of ferrous and ferric sulphate. The result anticipated is the solution of the oxidized copper compounds, thereby increasing the total recovery, and incidentally cleaning the sulphide particles from films of oxide so as to facilitate concentration in the flotation machines. The solutions would then be passed through the filtration plant to recover the dissolved copper. The outcome of these experiments will be awaited with keen interest.

## Michigan Copper-Tailing

Utilization of waste-tailing sand from the old mines in northern Michigan is attracting attention. Some of this tailing, such as that at the old Cliff mine, in Keweenaw county, now controlled by the Calumet & Hecla and its associated companies, are said to be richer in copper than that now yielding millions of pounds of copper yearly by the process applied for the treatment of the Calumet & Hecla tailing. The old sand-piles were deposited from 20 to 50 years ago, when milling was by no means a highly developed art, so that a great deal of copper that would now be recoverable from the ore was discarded with the waste. The Calumet & Hecla has proved that its sand can be re-worked, after being dredged from Torch lake, re-ground, and run through the leaching plant, at a cost of not more than 6c. per lb. for the copper recovered. The Tamarack, Quincy, Franklin, and other sand-piles contain great amounts of recoverable copper. Some of these have already been tested.—'Daily Metal Reporter.'

SPANISH CRUDE, unwashed, fine pyrite is still quoted at 16c. per unit of contained sulphur, and Spanish washed lump pyrite ore commands 16½ cents.

## Oregon Mines in 1917

Although receipts from Oregon at the mint and smelters in San Francisco show a decrease in the output of gold of \$75,000 for the first five months of 1917, as compared with the corresponding period of 1916, it is not an indication, according to Charles G. Yale, of the U. S. Geological Survey, that the mines of the State are less prosperous. Confirming this opinion, the copper output of Oregon increased 794%, so that the total yield of metal in 1916 increased \$939,969 or 47% over 1915. A steady increase in the copper yield is apparent this year, and the placer mines are also increasing their gold yield. The deep mines, however, are not producing as much gold as in 1916. As the copper output augments, so does that of silver. The Homestead Iron Dyke mine in Baker county, re-opened after years of idleness, is now by far the largest copper and silver producer in the State. In June last a new orebody was discovered on the 850-ft. level. A large concentrator has been constructed, and the flotation process is used. Other important deep-mine producers in Baker county are the Baker Mines Co., the Cornucopia Mines Co., and the Commercial Mining Co. The largest placer in the State is the Powder River Dredge Co., operating two dredges in Cracker Creek district. The Laclede mine, near Baker, has been re-opened this year; and the old Ben Harrison, at Sumpter, once a large producer, has been sold to Idaho men, who intend to make extensive development. In south-western Oregon the old Blanco, a beach-sand deposit in Curry county, between Port Orford and Langlais, is being equipped with new machinery to treat 500 tons of gold-platinum sand daily. The Nellie Wright mine, near Gold Hill, Jackson county, was recently sold to Salt Lake people, who are installing compressors and drills. The mine has a 25-ton Beers mill. The Cheney, Simmons, Ray, and Haff group of quartz claims, in the same county, has been sold to Californian capitalists, who are starting a new 1200-ft. adit. In Josephine county the Grayback copper group has been leased to owners of the California-Oregon Coast Ry., who also own the Queen of Bronze and the smelter at Takilma. Development on a large scale has been commenced. The Queen of Bronze is working 60 men and producing a good grade of copper ore. In Canyon district, Grant county, the Empire Gold Dredge Co. began operations in 1916, and has continued during 1917 with successful results. This is the third dredge operating in Oregon. There is considerable activity in the hydraulic mines, particularly in Baker, Grant, Jackson, and Josephine counties.

PAINT-MATERIALS are coming into greater demand, owing to an energetic movement under the slogan 'Use more paint,' undertaken by the National Paint, Oil & Varnish Association. Although having a selfish motive the propaganda is based on sound principles of conservation, and a nation-wide educational campaign will expound the function and use of paint as a preservative.

## Leadville Manganese Resources

Leadville, early famous for gold, and later for silver, lead, and zinc, has recently come into prominence as a source of manganese ore suitable for making spiegeleisen. For more than forty years 'black iron' has been mined for fluxing purposes from several of the Leadville mines, but only since the scarcity of manganese incident to the War became acute has any of it been diverted to the steel industry. At present about 500 tons per day is being shipped as manganiferous iron ore from the district, one of the large steel plants deriving most of its supply from this source. The ore, which averages from 20 to 25% manganese, 24 to 30% iron, and 10 to 15% silica, is reduced to the 33% spiegeleisen that is now being used with excellent results in both the bessemer and open-hearth practices.

"The manganese deposits at Leadville," according to J. B. Umpleby, of the U. S. Geological Survey, who recently examined them, "are distributed along the eastern edge of Poverty Flat, the middle and lower slope of Carbonate hill, and in Iowa gulch. One deposit of undetermined size has recently been opened on the west slope of Iron hill near the old McKean incline. At about this same topographic position is the McCormick shaft from which 2000 tons of low-grade ore (14% Mn) was produced.

"Few of the deposits crop out at the surface. Prospecting for them is determined by the records of earlier mining and by the occurrence of manganese in waste material on the dumps. In general the ore occurs in the blue limestone below the old lead stopes, but there are numerous exceptions to this, some of the old mines that produced very little lead or zinc being among the most important sources of manganese ore.

"In August 1917 ten mines were shipping, and since that time at least two others have entered the list of producers. Cramer & Co., operating the Star group, is the largest shipper in the district, with a daily output of about 250 tons. The other mines, most of them operated under lease, are shipping from 20 to 50 tons per day.

"Hand-sorting is a considerable item in the cost of mining as silicious nodules are common and seams of clay traverse most of the orebodies. In places also ground is being re-worked for the third or fourth time, and old timbers, waste dumped into abandoned stopes, and large areas of caved ground, must be contended with. On the other hand at every mine, except one, it is possible to dump the ore directly into the railroad cars. The large number of shafts available also serves to lower costs by reducing underground haulage to a minimum.

"One of the large deposits is in the Fair View or All Right No. 1 mine, where a mass of fairly homogeneous ore has been shown to be 120 ft. thick. Its areal extent has not been proved, although workings penetrate an area 200 by 75 ft., and similar ore is found 275 ft. west in the old Fair View shaft, 400 ft. north-west in the

Jason lease, and 300 ft. north in the All Right shaft. The ore as shipped runs 20% manganese, 30% iron, and 15% silica. The distribution of workings about this deposit and the fact that it is situated in an area not previously mined extensively, affords a better basis for estimating tonnage than in most of the Leadville manganese mines. It is by no means certain, however, that it contains more ore than two or three other deposits in the district.

"Any attempt to estimate the tonnage of manganese ore in Leadville is extremely hazardous. Old stopes, not recorded on mine-maps, are continually being broken into. Furthermore, the small cost of installation, together with the numerous faces of favorable appearance, discourages extensive development in advance of extraction. It is the opinion of the operators that the present rate of production might be doubled and maintained for a period of at least two years. This would call for about 750,000 tons of ore of shipping grade, but after an examination of all the producing mines, one is led to think that more than twice this amount may be produced if market conditions become slightly more favorable. It is reported that the present price for ore of between \$4 and \$5 per ton f.o.b. Leadville, leaves little margin of profit and does not encourage extensive development. Without doubt the rate of production can be increased rapidly for every reasonable advance in the base price."

LEGISLATION affecting mines in the Philippine Islands has engaged serious attention during the past year. The tax placed on the gross output of mines has not affected the mining industry as much as was anticipated. No company was forced to stop operation because of its application. The Bureau of Science has furnished information during the year on the wharfage tax. There can be no doubt that this tax retards mineral exportation, and it remains for the Legislature to decide whether the mineral resources of the Islands should be developed or should be conserved. The division of mines of the Bureau of Science is in a better position to know the needs of the mining industry and the defects and needed changes in the mining laws than any other department of the Government, and it is studying the question. Some of the old Spanish laws in regard to locating and working claims could be adopted to advantage. Under the present system a great deal of ground is being held for speculation to the detriment of development.

CEMENT is now being made from a by-product obtained in the manufacture of beet sugar, according to 'La Revue' of Paris. The first step in sugar-making from beets is to boil them, and a thick scum rises to the top. It has been customary to discard this, but analyses show that it contains large quantities of carbonate of lime. The amount of calcium carbonate recoverable from 100,000 tons of beets is about 6000 tons, and by adding to this the requisite amount of clay it has been found that, on being burned, it yields an exceptionally high-grade portland cement.

# Oxide of Zinc

By GEORGE E. STONE

\*The method for making oxide of zinc direct from the ore was invented and developed at the works of the New Jersey Zinc Co. at Newark in the middle of the last century. The process was invented by Burrows, who had not the ability, either financial or technical, to work out the economic details. This was done by John P. Wetherill, whose name is commonly attached to the process. The grate-bars used are also frequently called Wetherill grates, which is a misnomer because they were in common use for boiler-firing at the time and he never claimed originality for them. The development of the process was due to the efforts of the New Jersey Zinc Co. to find a profitable means of working the ores from Franklin and Sterling Hill, New Jersey. These are a mixture of franklinite, willemite, and zincite, containing about 20% zinc. The first attempts were to make spelter. These were not successful, owing to the low grade of the ore and the fusibility of the residue. The next attempt was to make oxide in large muffles and reverberatory furnaces. This succeeded, although the cost of operation was high, the recovery low, and the quality of the product uncertain. In 1855, the new process was patented and has been in successful operation ever since. Essentially, it consists in spreading a mixture of coal and ore on a body of burning coal on a perforated grate and blowing an excess of air through the grate. The zinc is reduced in contact with the coal, volatilized and burned by the excess of air in the upper part of the furnace and in the flues. It is then carried to the bag-rooms by the excess air and products of combustion, which are forced through the flues by fans. In its main features, the process is the same today as at the time of its invention, but the details have been so modified that it would hardly be recognized by its originators.

The process is applicable to all the oxidized ores of zinc and to roasted sulphides, provided the gangue is not so fusible as to leave a residue that is impervious to the blast. In many cases the ores contain impurities that make it impossible to produce an oxide of a color good enough to be available as a pigment. These impurities are volatile metals that form colored oxides or sulphides. Cadmium is one of the worst, because it is very volatile and its dark brown oxide and bright yellow sulphide both have strong tinctorial powers, so that small fractions of a per cent seriously injure the color of the oxide. Lead, which is one of the commonest impurities in zinc ores, also injures the color, though to a much less degree, as it usually forms basic sulphates which are nearly white. On other accounts lead is often objectionable, particularly when the oxide is to be used for the manu-

facture of rubber goods. Sulphur may occur in oxide as sulphides, sulphates, or as sulphurous anhydrides, the first and last of which are objectionable, the first on account of probable injury to the color, while the last is believed by many paint manufacturers to have a bad effect on the grinding properties. Opinion on the latter point is by no means unanimous. Sulphates, if soluble, have very objectionable qualities for outside paints as they are leached from the coat of paint, leaving discolored spots. Chlorides, in appreciable quantity, are rare, but if present would be open to the same objection.

The fuel must be one that does not produce a black smoke, as this would ruin the color of the oxide. In the West, where anthracite is expensive, semi-bituminous coals, low in volatile constituents, are sometimes substituted, but they are never as good. Coke alone does not work well, as it causes a very intense local heat that makes the residue impervious to the blast. It is occasionally used as a part of the charge-fuel. With silicious ores, limestone is sometimes added, but in general it does more harm than good, owing to its tendency to make the residue too fusible. The ores and coal are usually received at the works in fine enough condition for use without further crushing. Nearly all the ores consist of concentrates or roasted products inevitably finer than necessary. As small sizes of coal are suitable, and are cheaper, they are invariably used. If fluxes are used they are crushed to about the size of the ore and coal. There should not be a great difference in the size of the different materials, or it will be impossible to mix them properly.

The Palmerton plants of the New Jersey Zinc Co., in Pennsylvania, are the largest and best equipped oxide plants in the world. The general arrangement of the two plants is similar, but the east plant has fewer and larger bag-rooms and differs somewhat in details. At both plants the raw materials are delivered on the trestle at the south of the plant and are either placed in bins or stocked in piles. The ore and coal are taken from the bins to the mix-house by lorries. The mixed charges are delivered to the bins above the furnaces and distributed by traveling cranes. Each block of furnaces is a separate unit, having its own blower, exhaust-fan, and bag-room. The oxide is trucked from the bag-rooms to the packing-room and the final packages skidded or trucked to the storehouses.

The ore and coal are delivered on a double track, steel and concrete trestle, 22 ft. high, with Brown tangential bins below the track next the furnace-room. Materials for current use are dumped directly into the bins and the surplus is stocked back of the trestle by a bridge-crane

\*Abstract: Trans. A. I. M. E., St. Louis meeting, October 1917.

of 233 ft. 9 in. span equipped with a 10-ton Brown grab-bucket. This equipment also returns materials from the stock-piles to the bins when necessary. The charges are drawn from the bins to a weighing lorry, which has two hoppers, each containing a furnace-charge. These are carried to Ransome concrete-mixers placed at one end of the furnace-room. The mixed charges are elevated by a pair of counter-balanced skips to bins above the furnaces. From the bins the mixed charge is taken to the furnaces by cranes each having three hoppers holding one-third of a furnace-charge each, and each hopper is placed on a scale so that the charge is equally divided between the three. At the east plant all materials are delivered on a single-track, steel and concrete, trestle 47 ft. high, down the centre of the storage-yard. The materials are taken from this by a bridge-crane of 48 ft. 8½ in. span with a 2-yd. bucket and placed in elevated bins next the furnace-room. The ore and coal are stocked and reclaimed by the traveling bridge and by locomotive cranes on the high trestle. The total storage capacity is 200,000 tons of ore and 175,000 tons of coal. The fuel and the various ores are taken by bridge-cranes to small bins placed over the mixers. The materials are dropped from these bins into weighing-hoppers and from these into the Ransome mixers. The mixed charges are elevated to bins over the furnaces and then distributed by cranes much as at the east plant, except that there are no scales on the cranes or lorries. This arrangement of doing all of the weighing at the mixer on a fixed hopper is more satisfactory than weighing-lorries, because the latter are difficult to keep in adjustment.

The furnace-rooms at the two plants are similar, the main differences being that at the west plant the furnaces are carried on a concrete foundation and at the east plant on the floor. In both cases the furnaces are elevated sufficiently to allow the residue to be dropped into hoppers below the floor and then into cars. The framing of the buildings is quite different, the east plant being arranged to give more room for the charge-cranes. The west plant furnace-room contains 34 blocks of furnaces and the east plant, 26. All the blocks are alike, consisting of four furnaces 19 ft. 6½ in. by 5 ft. 11½ in. Each furnace has independent blast and flue-connections and three charge-openings in the roof surmounted by hoppers. Each furnace works three charges in 24 hr. The different furnaces of the block are charged alternately at 2-hr. intervals in regular order. Charging in this way, there is always one furnace starting, one nearly finishing, and two working strongly, and the volume and temperatures of the gases to be handled are nearly uniform at all times.

When the furnace is worked off the dampers in the flues are closed, cutting it out from the bag-room. The blast is shut off and the working-doors taken down. Three men work on the furnace at once, each having a separate door. The loose material on top of the charge is raked off and dropped on the floor close to the furnace. The clinker is then broken by heavy slice-bars and raked into hoppers under the floor. The furnace-men now

thoroughly clean the side and back walls from any clinker that has fused to them. When all of the old charge has been removed and the furnace cleaned, the grate is covered as rapidly as possible with a thin layer of coal, the doors closed and a light blast turned on. The coal is lighted by the radiation from the hot arch and it is important that it should light quickly and evenly. When the bed of coal is burning brightly, the charge from the hopper is dropped upon it and leveled. The doors are now closed, the blast turned on, and the furnace left to itself with occasional inspection to stop any blow-holes that may form. With the large charges that are now worked considerable time elapses before zinc vapor appears; when it does, the dampers in the flues are reversed, sending the gases and oxide to the bag-room.

The blowers for the oxide furnaces are direct-connected to motors, the wheels of the blower being placed on extensions of the motor-shaft. They are placed in small houses outside the furnace-room, two in each house. Each furnace has two outlet pipes, usually 20 to 22 in. diameter which lead up to the drum-pipe overhead. The drum has an outlet in the middle of its length leading to the exhaust-fans. Formerly the gases passed through a brick settling-tower between the furnaces and the exhaust-fan, but this is now usually omitted. The exhaust-fans are extra heavy plate-fans with special Hyatt roller-bearings and water-cooled shafts, belted to motors. Aside from the shafts, bearings, and extra thickness of plate, they are of the ordinary types. For convenience in attendance, a number are placed in one building. The west plant has four fan-rooms, three containing 8 fans each and one containing 10 fans. At the east plant there are two with 10 fans each and one with 6. From the exhaust-fans to the bag-rooms, in each case, run round pipes 3 ft. diameter, made of No. 16 sheet-iron and provided with numerous clean-out openings. In all cases, the pipes are arranged to give as nearly as possible the same length from furnaces to bag-rooms. This is done partly to equalize the friction in the different lines, but mainly to secure proper cooling of the gases before reaching the bag-room.

The method of collecting oxide in bags was first patented by S. T. Jones in 1852 and has been patented by others many times since. The bag-rooms at Palmerton vary considerably in size, the first two built holding bags enough for four blocks, while the latest contains the bags for 20. The larger rooms are more economical in labor and do not cause inconvenience provided the ventilation is equally efficient. The bags used are of heavy closely woven cotton sheeting, 22 in. diameter and about 40 ft. long. In the majority of cases the gases enter a header at the top of the room and from there pass to a series of parallel pipes from the bottom of which the bags are connected to hoppers, four bags to each, with a single collecting-bag tied to an outlet at the bottom of each hopper. At intervals the gases are shut off from the two lines of pipe connecting with a single line of hoppers, and the bags shaken. This pair of pipes is again connected to the main header and the next two lines shut off

and shaken. The frequency with which the bags are shaken depends upon the relative area of grate and bags, and the amount and quality of the oxide being made. The proper ratio of grate-surface to bag-surface has been a subject of much discussion. It varies in practice between 1:80 and 1:130. The amount actually necessary depends mainly on the efficiency of the ventilation of the buildings and the frequency of shaking. A well-ventilated room will consume no more muslin with a ratio of 1:80 than a poorly ventilated one with a ratio of 1:130. Recent experiments indicate the probability that a well-ventilated bag-room with a mechanical shaker operating at short intervals will allow a great reduction in the necessary bag-area. The collecting-bags are removed from the hoppers every 24 hr., or oftener if necessary, and taken to the packing-room. This is done by a trucking gang that removes the filled bags and replaces them with fresh ones, trucking them by hand to one side of the bag-room, where they are coupled together and the train drawn to the packing-room by a motor.

The packing-room is a four-story building of mill construction. The trucks are hauled into the ground floor and then taken one by one on a platform-elevator to the upper floor. There are a number of openings in this floor leading to bolters on the floor below. Around each opening is a wide shelf on which the bags are placed while their contents are emptied into the bolters. The third floor contains nothing but the bolters, and a room for sewing and making bags. The bolters are of the ordinary types used in flour-mills. The packing-machines are arranged in four lines on the second floor. They are also of a type largely used for flour. There is usually one packer below each bolter and fed directly by it. In some cases, owing to the lack of room, one bolter feeds two packers. The oxide is packed partly in paper bags holding 50 lb. each, partly in barrels with 30-in. staves and 19½-in. heads, holding 300 lb., while material for export is packed in special barrels and weights to suit the different markets. The barrels are kept in a storage-room where the hoops are driven by a machine and then nailed by a second one, and from here they are passed to the packers. All barrels are weighed empty and filled, the weights adjusted, and the barrels headed. They are passed to the ends of the building and rolled on skids to the store-houses. The second floor

of the packing-room is high enough above the ground-level to allow sufficient slope to the skids to carry the barrels to all but the most distant store-houses. The paper bags are loaded on trucks and taken to the store-houses on the same skidways.

Power for both plants is supplied from a central station between the oxide and the spiegel furnaces. The boiler-room is equipped with Edgemoor boilers of 536 hp. each, which can be fired with coal or with the waste-gases from the spiegel furnaces. The engine-room parallels the boiler-room and is about 20 ft. north of it, and contains three horizontal cross-compound blowing-engines for the spiegel-furnaces; four direct-current generators, two of 500 and two of 600 kw., each direct-connected to a horizontal cross-compound Corliss engine; three Allis-Chalmers turbo-generators, two of 2000 and one of 4000 kw., 6600 volts, and three phases; two motor-generator sets used as a reserve for both alternating and direct-current lines, as either part can be used as a motor to generate current of the other kind, if needed. In addition, the engine-room contains the exciters, condensers, and pumps.

The ores used at Palmerton consist almost entirely of concentrate from the company's mines at Franklin Furnace and at Sterling Hill, New Jersey. Three of these products are smelted for oxide, namely, franklinite, 'half and half,' and dust. The composition of these is about as follows:

	Franklinite %	Half and half %	Dust %
Zn .....	18.2	18.4	17.6
Fe .....	35.0	15.2	20.1
Mn .....	12.8	12.2	8.9
SiO <sub>2</sub> .....	3.6	12.6	7.2

The franklinite is worked by itself and the residue smelted in blast-furnaces for the production of spiegel. The 'half and half' and dust are mixed, and the residue wasted, as it contains too little Fe and Mn and too much SiO<sub>2</sub> to be a profitable smelting material. Franklinite is the easiest to work and gives the best product. The 'half and half' and fine are mixed and worked together. The charges per furnace average:

	Ore tons	Coal tons
Franklinite .....	2.62	1.62
Half and half and fine.....	1.95	1.36

The recovery for franklinite averages about 86% and for the 'half and half' and fine about 78%. The recovery and quality of product are controlled by the selection of the ores, the ratio between ore and coal and of both to the grate-surface, and, what is of great importance, the balance of the blast and exhaust and the proper proportioning of both to the charge being worked. Where leaded ores are treated the charges and recoveries vary more so that average figures are of little value. In general, with such ores, the charges are little lighter and the recoveries lower than for the New Jersey ores. The recovery of lead is usually better than of zinc, roughly as 9 to 8. The output of oxide is generally estimated as

equalling the combined Zn + Pb in the ore, the gain in O and SO<sub>3</sub> nearly balancing the losses in Zn and Pb.

The product is divided into five grades, two for the use of paint manufacturers, two for rubber, and an off-grade that is re-worked either for oxide or spelter. For the paint trade, the grading is entirely by color, samples being daily rubbed down with oil and compared with standards. For the rubber trade, slight variations in color do not make so much difference, and the grading in this respect is not so close, but freedom from lead and absence of small hard particles is insisted upon. The variation in composition of the different grades is very slight. The material as shipped uniformly contains 99% or more of ZnO, the principal impurities being: SO<sub>3</sub>, 0.25 to 0.33%; moisture, 0.10 to 0.50%; and PbO, 0.05 to 0.30%. The principal use of zinc oxide is as a pigment and for this purpose its purity of color and freedom from discoloration by gases and atmospheric conditions, fineness, and uniformity, make it particularly useful. As a pigment it has the disadvantage of slow drying and a tendency to become unduly hard in time. The general consensus of opinion among paint manufacturers is that a mixture of pigments is better than any single one. In these mixtures, zinc oxide is an almost invariable constituent because it prevents 'chalking' and gives a surface that retains its color. Next in importance is its use in rubber goods, in which it is employed as a pigment to produce white goods. It is excellent for this purpose, when practically free from lead. If this were the only effect it might be replaced by cheaper materials, but it also greatly increases the tensile strength of the resulting rubber. A mixture of pure rubber and sulphur when vulcanized has a tensile strength of about 2000 lb. per square foot and an elongation of 960% of its original length. The effect of adding zinc oxide is to increase the tensile strength but diminish the elongation as shown below:

ZnO %	Tensile strength	Elongation
	Pounds per sq. in.	%
25 .....	2400	720
35 .....	2400	700
45 .....	2700	680
55 .....	2500	620
65 .....	2000	540
75 .....	1300	400

It will be seen that up to a content of about 60% the ZnO increases the tensile strength of rubber. No other material tested has this effect.

As the supply of lead-free ores is limited, and as the demand for ZnO is increasing, much 'leaded' oxide is being made. The process is the same, but the furnace-charges are usually lighter and the recovery lower. In most cases the furnaces used are double-ended with one or two working-doors at each of the opposite ends. This makes the furnace easier to clean, as there is no back-wall, which is the most difficult part from which to cut accretions. On the other hand, this type of furnace cools more when charging and does not, as a rule, light up as quickly. Which type is better is still an open

question. In making 'leaded' oxide, it is customary to have a brick combustion-chamber over, or close to, the furnace. This insures sufficient time of contact at a proper temperature to cause the lead to be converted into basic sulphate. This is essential, as all of the oxides of lead are strongly colored and injure the color of the product, while the basic sulphate is very nearly white and does not have this effect. In many cases the bag-rooms of the works making 'leaded' oxide have no overhead distributing pipes, the hoppers being connected and used for this purpose. Leaded oxide is divided into several grades, depending on the amount of lead it contains. This is always stated as the amount of neutral sulphate (PbSO<sub>4</sub>) equivalent to the total lead present, although it is always present mainly as a basic sulphate. It forms an excellent material for the manufacture of mixed paints. So far this grade has not proved satisfactory to the rubber manufacturers. It is impossible to give the production of oxide of zinc, as the statistics are not published by the Government. Such figures as have been published are not comparable, because the grouping of the different products is not always the same. The increase has been very rapid, especially within the last three or four years.

## Paints and Painting in the Tropics

Arrangements have been made at the Miraflores purification plant in the Panama Canal zone for a central laboratory for the inspection and testing of paints used on canal structures and equipment. The purpose is to make a study of formulas and methods of application and determine the best processes of protecting woods and metals in varying circumstances in the tropics. Expenditures by the Canal administration for paint materials amounted to \$127,173.44 in 1914; \$255,366.56 in 1915; and \$229,463.58 in 1916. There are five paint-grinding machines at the Balboa shops supplying paint for the general needs of the canal, and one at Pedro Miguel lock, which does work for all locks. The problem of painting has never been solved, although practically every kind of paint that is made has been tried on the Isthmus, and tests have been made in coating with concrete and with metal sprays. There are now between 15 and 20 steel plates coated with various mixtures exposed at the lower end of the Miraflores locks for tests under weather and water, in intermittent and constant submersion. The determination of the most effective protection is to be made the subject of special study.

FERRO-MANGANESE is sold in England for domestic use at £25 per long ton under government control of prices, but for export a basic price of £80 per ton is taken. Consequently British ferro-manganese sells for \$325 to \$375 per ton in American sea-board markets. Meanwhile 'prompt domestic,' of American manufacture, brings \$275, and fourth quarter prices are approximately \$300 per ton.

# Flotation Tests With Hardwood Oils

By R. E. GILMOUR and C. S. PARSONS

\*The most promising wood oils were tested at Cobalt under commercial conditions. Three hardwood oils were given a thorough trial at the Buffalo mines in comparison with a standard pure pine-oil (G.N.S. No. 5). They are as follows:

F.P.L. No. 26, heavy hardwood creosote-oil.

F.P.L. No. 27, acid (creosote) oil.

F.P.L. No. 29, ketone residue.

These oils are quite uniform in the crude state as produced and can be considered standard flotation-oils. The hardwood oils used in these large-scale tests were supplied from the plant of the Standard Chemical, Iron & Lumber Co. of Canada, Ltd., at Longford, Ontario.

Samples of these three oils when examined at the Forest Products Laboratories showed 8.55%, 5.25%, and 2.55% respectively, of water. The aqueous fractions of the first two were distinctly acid and strong enough to corrode ordinary iron metal-containers. The water content of the ketone residue was natural. Although the hardwood oils can be used with the small percentage of water present mostly as an emulsion, the removal of the aqueous fraction seems strongly advisable, not only on account of the above objections but by reason of the fact that the acetic acid and its homologues forming the acid content are essentially of no flotation value. The higher aqueous content of heavy hardwood creosote oil No. 26, compared with acid oil No. 27, is due to its lighter specific gravity. The mixing of these two oils in the proportions in which they are produced commercially would be advisable, since the value in flotation of each oil is equally satisfactory. In this way a better gravity separation of the water content could be effected than would be possible with oil No. 26 alone. The yields of these two oils, No. 26 and 27, are respectively 0.486 and 0.284 imperial gallons per cord. Figuring on 500 cords of hardwood distilled per day, this means that 385 gal. of this Canadian wood-oil product is available. For about 2000 tons of silver ore treated daily at present, only slightly more than 25% of this oil supply can be consumed in the Cobalt area. Should the demand for these hardwood creosote-oils become greater than the supply, it is interesting to note that oil No. 25B, according to laboratory results, is equally satisfactory. As yet hardwood creosote-oil mixture No. 31, comprised of oils No. 25, 26, and 27 in the proportions produced, has not been tried in actual milling at Cobalt. Although small-scale laboratory experiments on the creosote-oil mixture in the crude state show good comparative results, the indications are that after the removal of the fraction that

distills below 150° C., and that has a gravity below 0.89, the mixed residue corresponding to oils No. 25B, 26, and 27, would give excellent results with Cobalt ores. Treating oil No. 31 in this way by a preliminary distillation would also remove all the aqueous content and would give a desirable water-free flotation-oil. The commercial supply of this crude hardwood-creosote mixture after such treatment would be over 500 gal. per day in Canada.

The proposed specifications for hardwood creosote-oils are as follows: Oils No. 26 and 27 with 17.5% and 10% respectively, distilling below 150° C., including 8.55% and 5.25% aqueous content, have been found to give satisfactory flotation results when used in the crude state. Calculating to the water-free oil basis this means that these two crude oils contained respectively 9.8% and 4.9% of moisture-free oil distilling below 150° C., according to the standard method of fractional distillation for the examination of crude oils proposed. Taking these two crude oils as a standard, and keeping in mind the hardwood creosote-oil mixture No. 31, with the aqueous and lighter oil-fractions removed, as suggested above, it would seem that the general specifications as given below would be fair restrictions to propose for the buying of hardwood creosote-oils, to be used as selective frothing-agents for Cobalt ores. (1) The aqueous content should be less than 5% of the crude oil as received. (2) Not more than 10% of the water-free oil shall distill below 150° C. (corrected temperature), and with specific gravity below 0.89 at 15° C., according to the standard method of fractional distillation outlined. (3) At least 65% of the water-free oil should distill between 200° C. and 265° C., where the gravity shall be between 0.975 and 1.065. (4) Not more than 15% of the water-free crude oil shall remain as a hard pitch or coke-residue. These specifications would not apply to ketone residue, which is somewhat different in nature from the creosote-oils. Where a high-grade concentrate is not desired, and the aim would be to lift considerably more mineral-bearing gangue in order to reduce the tailing-assay, considerably more pitch residue than indicated in the fourth specification may be used. This, however, may be accomplished by adding hardwood tar as such, containing over 70% pitch residue, to the total oil-mixture.

LARGE-SCALE TESTS. The tests carried on during 42 continuous shifts were made in large Callow cells without interruption of the general procedure. During the first 26 shifts the standard mixture of pine-oil and coal-tar products was used. In the remaining 16 shifts the hardwood-oils were substituted for pine-oil in the following order: Heavy hardwood creosote-oil No. 26 in 6

\*Abstract: Bull. Can. Min. Inst., Nov. 1917.

shifts, acid oil No. 27 in 5 shifts, and ketone residue No. 29 in the last 5 shifts.

#### TESTS WITH PINE-OIL MIXTURE

Oil-mixture—Pine-oil (G.N.S. No. 5).....	20	%
Coal-tar creosote .....	60	
Coal-tar .....	20	

Oil-mixture per ton of dry ore, 1.06 lb.

Shift	Ore treated tons	Silver, oz. per ton—				Recovery Con- centrate	%
		Heading	Tailing	Middling	con-		
7-3	248	6.2	0.9	8.4	381.0		85.5
3-7		6.8	1.0	20.0	417.5		85.3
7-3	327	9.0	1.0	9.8	392.0		88.9
3-7		8.6	1.0	10.0	480.0		88.4
7-3	316	8.6	1.0	10.4	421.0		88.4
3-7		8.8	0.9	12.8	528.0		89.8
7-3	283	8.2	0.9	8.0	355.0		89.0
3-7		7.8	0.9	10.0	365.0		88.5
7-3	265	7.8	1.0	8.0	481.5		87.2
3-7		9.0	0.9	14.9	473.1		90.0
7-3	297	8.2	0.9	9.0	465.0		89.0
3-7		7.8	0.9	11.6	447.0		88.5
3-7	247	9.0	1.0	16.0	462.5		88.9

#### TESTS WITH HARDWOOD-OIL MIXTURE

Oil-mixture—Hardwood acid (creosote) oil (F.P.L. No. 27) ..	40	%
Coal-tar creosote .....	50	
Coal-tar .....	10	

Oil-mixture per ton of dry ore, 1.06 lb.

Shift	Ore treated tons	Silver, oz. per ton—				Recovery Con- centrate	%
		Heading	Tailing	Middling	con-		
3-7	187	12.0	1.1	92.0	900.0		90.8
7-3	283	9.6	1.2	15.2	320.0		87.9
3-7		7.0	1.0	22.8	732.5		85.8
3-7	125	8.8	0.9	10.6	435.0		89.9
7-3	80	8.8	0.8	10.6	344.0		91.1

The tables speak for themselves. These tests gave more than 20% higher recovery than were obtained in small-scale laboratory tests. The operation of the flotation machines needed no special attention during the tests on the hardwood creosote-oils No. 26 and 27. When using ketone residue, however, care had to be taken to keep out traces of foreign oil such as lubricating-oil which had a deleterious action on the somewhat sensitive though heavy froth.

**CONCLUSIONS.** 1. Crude hardwood-oils, the supply of which is abundant, can be substituted for pine-oil as a selective frothing-agent in the commercial flotation of Cobalt silver ores.

2. Heavy hardwood creosote-oil, F.P.L., No. 26 and acid (creosote) oil F.P.L. No. 27, give equally satisfactory results and a mixture of these two oils in proportions as produced is recommended as a standard hardwood flotation-oil.

3. Ketone-residue in the crude state can also be considered a satisfactory flotation-oil for practical use on Cobalt silver ores.

Hardwood creosote-oils have been tested on a laboratory scale with copper ore from Bruce mines, Ontario. From ore assaying 7.9% copper a mixture of 40% heavy hardwood creosote-oil, F.P.L. No. 26, 54% tar-creosote

and 6% coal-tar gave 93.1% recovery, leaving tailing with 0.8% copper. Other hardwood-oils should give equally satisfactory results. Ketone residue has proved satisfactory for the flotation of low-grade copper-nickel ore in the Sudbury district and a commercial demand for the oil has already been effected as a result of this investigation. Hardwood creosote-oils, especially light hardwood creosote-oil, F.P.L. No. 25, has promising qualities for the treatment of the lead-zinc and the copper ores of British Columbia. Further investigations on the flotation problems of other Canadian ores, especially those from British Columbia, are now being conducted in the ore-dressing division of the Mines Branch, which has secured a complete collection of the Canadian crude wood-oils and their fractions.

## Life of Cast-Iron Pipe

Cast-iron, especially in the form of pipe, seems to last longer than any other form of steel or iron. Some remarkable records have been reported. There are records of pipe in use in Europe for over 200 years. In this country, and particularly on railroads, such long-time service is not recorded because of the limited time that these pipes have been in use. In the early years of American railroads, water-service was given with pipes of less than 3 in. diameter and the use of cast-iron pipe in consequence was limited to cases where 3-in. or larger pipe was used. Instances of installations of cast-iron pipe were recently made the subject of study on the Illinois Central railroad. The life of several of these lines has been traced to the present time. The most interesting is that of a pipe-line laid at Centralia, Illinois, in 1855. This was of 4-in. cast-iron pipe approximately 10,000 ft. long. After 12 years of service it became inadequate for the increased consumption, and upon examination it was found to be heavily encrusted. Efforts were made to improve its capacity by cleaning it and relaying a part of it with clean-out boxes at intervals of 100 ft. This provided only a temporary relief and the following year about 5000 ft. of the line was taken up and re-laid with 8-in. pipe, which is still in service after being in the ground 49 years. The 4-in. pipe relieved at Centralia was re-laid in 1868 at Ramsey, Illinois, where it remained in service until 1903, when it again became too small for the demand and was replaced by 6-in. pipe. Since that time the old 4-in. pipe has been used at various places, principally as drains. Another installation of which authentic records are available is one of 7500 ft. of 4-in. cast-iron pipe at Little Wabash river, laid in 1857. This remained in service until July 1893, when it was replaced. The old pipe was stored at Centralia until 1895, when portions of it were re-laid at that place and at Effingham and at Big Muddy. The installations at the last-named places have since been removed but the pipe at Centralia is still in service. No sign of paint can be found on the pipe at the present time and apparently it never had been painted.

# REVIEW OF MINING

## TONOPAH, NEVADA

TONOPAH BELMONT.—WEST END CON.—MACNAMARA.

The Tonopah Mining Co. shipped 34 bars of bullion, valued at \$62,400; this represents the final clean-up for October. During the previous week 2700 tons of ore, averaging \$13 per ton, was milled. In the Silver Top 57 ft. of development has been done, and 112 ft. in the Sandgrass. At the Red Plume shaft stoping continues on the Red Plume vein on 3 ft. of ore. Last week the production was 2500 tons.—The Tonopah Belmont Development Co. shipped 40 bars of bullion and 27 tons of concentrate from the Belmont mill, and 29 bars of bullion and 20 tons of concentrate from the plant at Millers. The value of the shipment was \$121,930. On the 800-ft. level raise No. 16 shows 3½ ft. of good ore, and raise No. 17 from the north-east drift No. 8006 shows 6 ft. of excellent ore. On the 900-ft. level north-east cross-cut No. 9019 is being driven to intersect the South vein. On the 1000-ft. level a raise is being driven to cut the extension of the North vein. Last week's production was 2438 tons.—The Tonopah Extension Mining Co. shipped 23 bars of bullion, valued at \$46,500. In the Victor 101 ft. of development has been done, and 121 ft. in the No. 2 shaft. At the No. 2 shaft on the 1350-ft. level the development in the intermediate east drift No. 504 exposed a 2-ft. face of ore, in the west drift No. 510, 3 ft. of ore, and 3 ft. in the east drift No. 510. The stopes on this level were the Murray vein 5 ft., O. K. vein 3 ft., and Merger vein 3 ft. On the 1680-ft. level of the Victor, drifts have been started to the east and the west to prospect the Merger vein which was discovered recently. The flow of water at this level has slackened. The production for the past week was 2380 tons.—At the Ohio shaft of the West End Consolidated Mining Co. cross-cut No. 506 is in foot-wall quartz. Drift No. 526 is being driven on a high-grade hanging-wall stringer. A sill stope is being started in drift No. 530. Drift No. 531 continues to show a full face of high-grade ore. No. 454 drift No. 2 shows a full face of fair ore. On the 555 intermediate level, drifts No. 1 and 3 show a full face of good ore, while raise No. 3 is being driven for the purpose of a connection. At the West End 623 raise No. 7 has exposed considerable ore. The output last week was 1154 tons. Development on the 1700-ft. level of the Halifax Tonopah will be resumed soon. The tonnage the past week was 54 tons.

The MacNamara Mining Co. is treating 70 tons of ore per day. On the 300-ft. level stope No. 1 is producing fair ore from both the foot-wall and the hanging wall. Stope No. 2 shows a 6-ft. face of good ore. On the 625-ft. level good-grade ore is being broken on a 6-ft. face in stope No. 1. Development on the 725-ft. level consisted in advancing drift No. 18 on a 6-ft. face of quartz. The output last week was 487 tons.

The Jim Butler Tonopah Mining Co. produced 850 tons of ore last week. The recent shipment of bullion and concentrate from the Millers plant of the Tonopah Belmont company represents the production of the Jim Butler for the last half of October. The value was \$29,837.—At the Cash Boy the hanging-wall drift on the 1700-ft. level was extended 25 ft. in ore, assaying \$22 to \$60 per ton.—The Great Western Consolidated Mining Co. will resume operation as soon as the Nevada-California Power Co. can furnish uninterrupted power

service. The auxiliary plant of the power company is nearly completed.—The week's production at Tonopah was 9863 tons with a gross value of \$172,602.—The addition of a compressor and air-drills at the Kanrohat property, in the Round Mountain district, has facilitated development.

## MANHATTAN, NEVADA

WHITE CAPS.—MANHATTAN CON.—UNION AMALGAMATED.

The mine work covering the week ended November 8 at the White Caps is as follows: from the 300-ft. level, raise 303, being extended in the foot-wall of the shaft orebody for mining purposes, has broken into the orebody, and shows ore aver-

NEVADA

aging two ounces in gold. Four feet of progress is reported; the raise will be discontinued and a stope started from it. On the 300-ft. a sump is being cut east from the shaft beyond the east fault for the purpose of obtaining a supply of water for domestic purposes, as there is a spring of pure water at this point. When this work is completed the sump will be concreted, a pipe-line extended to the shaft, and the water pumped to the surface and placed in a cistern, to supply the White Caps and White Caps Extension. From the fifth level, south cross-cut No. 502, from 501, has been discontinued. A raise has been started which will be extended to connect with the fourth level. This raise will be entirely in ore. The west cross-cut, No. 503, being extended to prospect for the shaft orebody, has made 28 ft. through an area of shale and quartzite. No. 504 south cross-cut has just been started to cross-cut the east orebody, and 14 ft. has been made, all in ore. The

south cross-cut, No. 501, running on the east orebody is now 399 ft. from the station, the last 167 ft. being in ore. A full face of ore shows, with a foot of same averaging two ounces in gold. The distance made driving east is 36 ft. The new work started is the 500-ft. sump, which is being excavated preparatory to the resumption of sinking the shaft one more lift. Thirty cubic yards has been taken out from this sump. The summary for the week shows a total of 48 cu. yd. of excavation and 82 ft. gained. In the White Caps mill over 125 tons is crushed per day. The Butters filter, which is one of the improvements to be added, is now being made in the Tonopah Extension workshop, the complete change in the mill is expected to be finished in two weeks. The clean-up of precipitates from the mill has been shipped to the Tonopah Extension for treatment.

The east orebody of the Manhattan Consolidated has been exposed from the fourth level during the past week. The east drift had been extended 200 ft. from the shaft. After 10 ft. had been made with the cross-cut the orebody was cut and since then 20 ft. has been made across the orebody with no signs of hanging wall in sight as yet. The late developments have proved the orebody to be continuous from the surface to the 400-ft. level with incline distance of over 450 ft. The management plans to immediately continue the shaft-sinking for an additional 200-ft. depth, as soon as the east orebody has been developed from the fourth level.—The Union Amalgamated has confined itself to shaft-sinking during the week. Two shifts in the raise being extended from the 600-ft. level to connect with the Earl shaft have been employed and the distance made is now 37 ft. above the level. This raise should hole-through into the shaft bottom in about twelve days. After connection is made the completion of the enlargement work on the shaft will be greatly facilitated as the waste can then be dropped to the 600-ft. level and raised to the surface from the Bath shaft. Three shifts have been employed in the Earl shaft, and at present the shaft has been enlarged and timbered for a distance of 84 ft. The last 36 ft. has been in very treacherous ground.—In the Manhattan Red Top the shaft has been sunk 60 ft. No material change in the formation has been noted. The flow of water has increased to some extent but is being handled without much trouble. The total depth of the shaft is 167 ft. vertical.—The operations by the White Caps Extension and Zanzibar companies in the sinking of the shaft for the benefit of both companies have been maintained steadily. The three-compartment vertical shaft has reached a depth of about 370 ft. It is intended to sink the shaft to about 390 ft. and from that point the first station will be cut and cross-cuts extended to explore the formations for orebodies.

## PLATTEVILLE, WISCONSIN

VINEGAR HILL.—GRASSELLI CHEMICAL CO.

In the Cuba district, noted for the operations of the National Zinc Ore refinery, operations were uninterrupted and shipments of high-grade ore were heavy from both this and the Linden Zinc refinery. The raw-ore deliveries to the National Separators all came from the Vinegar Hill mines, showing that this was the heaviest producing group in the field. A portion of its output was sent to the Grasselli Chemical Co., the National Separators being unable to treat the entire output. The C. S. H. Mining Co. has completed a new mill and shipped concentrate to the Benton Roasters. The Connecting Link Mining Co. bottomed two shafts in ore on the old Dall range. The Big Eight Mining Co. is assembling material for a new mill on the Raisbeck mine. Drills were kept busy proving spar ranges on the Gritty-Six lease for William Raisbeck, former owner of the Black Prince mine. The Connecting Link was incorporated with a capital of \$60,000.

The Benton contingent of zinc miners made heavy deliveries

to the Grasselli Chemical Co. The leading producers were the Wisconsin Zinc Co., Frontier Mining Co., Vinegar Hill Zinc Co., New Jersey Zinc Co., and the Fields-Thompson mine. The Vinegar Hill Zinc Co., after much underground development at the Martin Kittoe, and Blackstone mines, is in much better shape and increased deliveries were made the second half of the month. The new Meloy mine is showing an improved grade of ore, at times exceeding 50% zinc. The Wisconsin Zinc Co. met with exceptional success in work at the Thompson, Champion, and Longhorn mines. The New Jersey Zinc Co. had three good producers in the Fox, Penna-Benton, and Hoskins mines. The Fields Mining & Milling Co. more than doubled the zinc output from the John Thompson mine. Operating conditions will be greatly benefited by the completion of a new branch railway connecting with the main line of the Chicago & Northwestern railway.

## CASPER, WYOMING

BIG MUDDY.—WEST SALT CREEK.

Developments in the Wyoming oilfields within the past few months have been almost sensational enough and important enough to form the basis for a boom of old-time proportions. Old-timers, followers of the boom-towns—Leadville, Cripple Creek, the Klondyke, Nome, Goldfield, Oatman, and Tulsa—unite in saying that Casper is the best of all. The growth of Casper and the development of surrounding country are based on a firm foundation. Oil is coming to the Casper refineries from a dozen fields, meaning that railroads, refineries, and all allied businesses are employing full crews and enjoying prosperity. Casper is being built rapidly and substantially. It claims a population of close to 14,000 and the fact that it has a capacity for housing only one-half that number has caused congestion. Basement rooms, attics, woodsheds, and private garages have been pressed into service for sleeping quarters, and hotels with cots in halls and extra beds in rooms turn away guests every night.

Big Muddy gave Casper its great impetus about a year ago. This field is on the railroad 18 miles east of Casper. Deep drilling has been fruitful of remarkable results. Four distinct oil-bearing sands have been found within reach of the drill. The Shannon sand, at 1000 ft., is spotty. At many points it has been found water-bearing, but the Producers company recently finished the best well in the field in this sand. The well makes upward of 1000 bbl. per day. The Kinney sand, at 1900 ft. has been an abundant producer where tapped, but it does not appear to be of great extent. The same may be said of the 'stray' sand, found in the east part of the field around 1600 feet. But the best sand of all is the Wall Creek, found at 3000 ft. Twelve wells have so far been driven to this sand and all but one are flowing. The oldest, which was started just a year ago, is making better than 200 bbl. per day. Deep wells on Big Muddy are expensive to drill. Cable drills do not operate satisfactorily in the soft and crumbly shales, but the big rotary rigs have been found efficient. So far the fastest time made in completing a deep well is 47 days. On the other hand some holes started months ago still are unfinished. Big Muddy has been connected with Casper by a pipe-line operated by the Illinois Pipe Line Co., and the daily production of the 80 wells in the field is bought by that company on a base price of \$1.15 per barrel. Standard Oil interests are dominant at Big Muddy. The Producers Oil Co., a subsidiary of the Texas company, has made good progress in developing its holdings in this field and now has a number of producing wells.—West Salt Creek has been the sensation of the year in the Casper district, for Big Muddy was assured, though not proved, in 1916. This district embraces a territory west of the Government's Salt Creek Naval Reserve, and lying entirely outside of the escarpment. In this field three sands are within reach of the drill. The first, Wall

Creek, a wonderfully productive sand in the main Salt Creek, here is found to be water-bearing, but beneath it are two other sands, the first of which yields oil, and in the second, which soon will be tapped by the Bessemer company, oil has been found along fault-planes in the shale. Since the Hjorth well brought in oil in the second sand early this year, this district has been the scene of much activity. Probably 75 rigs have been erected and fully as many more ordered. The long haul from Casper has delayed development. West Salt Creek is 50 miles from the railroad over one of the worst wagon-roads that trucks and teams ever tried to negotiate. Some idea of the road may be had when it is stated that the regular rate for freighting from Casper to the field is \$30 per ton.

All of the Salt Creek production goes to the Midwest refinery at Casper, through two pipe-lines. The Midwest Oil Co. owns or controls nearly all of the production of Salt Creek and buys the balance on a basis of \$1.15 per barrel. The field produces about 15,000 bbl. of crude oil per day. A casing-head gasoline plant is just being completed that will materially add to this company's revenues. To convey this volatile product to Casper a line of 4-in. pipe, with welded joints, has been laid.

The Lander field is being rapidly developed, and, with Grass Creek, Elk Basin, and Greybull, is contesting for third place in point of production. Partly developed fields, where either oil or good indications have recently been found, are Powder River Station, Tisdale, Notches, Poison Spider, Lost Soldier, Buffalo Basin, Thornton, and Old Woman Creek. Development has been started on Midway, Buck Creek, Big Sand Draw, Government Draw, Castle Creek, East Salt Creek, Rumford, Emigrant Gap, North Casper Creek, Bates Hole, Big Hollow, and a score of others.

## HOUGHTON, MICHIGAN

AHMEEK.—ALLOUEZ.—OSCEOLA CON.—CENTENNIAL.

The October output of copper from the mines of the Michigan district was the largest since March, and November promises to show a further increase. Three or four of the mines are again working normal forces and others are increasing their crews steadily. By December, Michigan mines may again produce at the rate of 20,000,000 lb., despite the loss of hundreds of the best miners who have gone into the service of the Government. Ahmeek will probably show a production of over 30,000,000 lb. for the present year, compared with a little better than 24,000,000 lb. last year. This is one of the few mines that will show a larger output in 1917 than 1916. Ahmeek has the advantage of youth, rich material, good management, and fine treatment of employees. Young miners are glad to get work at the North Ahmeek particularly. The tonnage of ore is increasing daily and the production is averaging better than 22 lb. per ton. This mine did not follow the policy of sending down all of its richest stuff when prices were high, a few months after the War started, and the result is that today it has as rich an ore-reserve as any mine in the district.—Allouez, another Calumet & Hecla subsidiary, will come close to a production of 10,000,000 lb. this year, if the increase for November and December comes up to expectations. This mine reasonably can be expected to produce at this rate for at least ten years to come. The grade is 18 lb. per ton, and, while this may be maintained for several years, it cannot be expected to continue indefinitely.

The future of the Osceola Consolidated depends on further economic changes that will make possible the profitable operation of a grade of ore lower than anything handled in the past. There can be little expectation of any increase in the proportion of copper secured in the North Kearsarge shafts with greater depth, unless the history of every ore-formation in this district changes, as the copper content of the Lake Superior ores do not increase with depth.—Production at

the Centennial is not heavy, but the yield for the present year will be close to 2,250,000 lb., an increase of at least 750,000 lb. over 1916. This is due to an improved quality of ore and a slight increase in tonnage. The Centennial now is into all of the Wolverine richness that its cross-cuts have been seeking.—Because of the delay in securing a right of way for its railway the Seneca has been handicapped considerably in preparing for shaft-sinking. At the present time, however, the Seneca has a fine surface prospect and shaft-sinking will commence in a short time.

## MAMMOTH, UTAH

CALIFORNIA-COMSTOCK.—HECLA DIVIDEND.—ORE SHIPMENTS.—CHIEF CONSOLIDATED.

The entire Tintic mining district is hard hit with the embargoes and car shortage, the total shipments of first-class ores being only 127 carloads with an estimated weight of 6000

tons and valued at \$165,000.—J. C. Jensen, general manager of the Park City mine, reports that during the month of October two important strikes were made at the California-Comstock. One of these strikes was made on the 300-ft. level of the Comstock. In a drift started to the south-east from the bottom of the winze a full face of a splendid lead-silver-zinc ore was uncovered, giving promise of a large tonnage. The other strike was made in the bottom of what is known as the 250 lead-zinc stope, where two feet of high-grade ore was exposed.—An assay of the ore gave 55.8% lead, 4.14% copper, 14.2 oz. silver, and 9.1% zinc. The equipment and buildings at the property have been overhauled and repaired during the last few months so that everything is in shape for continued operations regardless of weather conditions.—With the rais-

ing of the embargo on lead-zinc ores the Rico-Argentine's production will be greatly increased. In October it shipped 875 tons to the smelters. The marmatite ore is netting about \$300 for each small carload; it carries 5% copper, 6 oz. silver, and a little gold. During October 49 carloads of ore containing 35 tons each were shipped from the Michigan-Utah mine at Alta.—A rich strike has been made at the Lehi-Tintic, 2100 ft. from the mouth of the adit. The face is fully 600 ft. deep and carries 6 oz. of silver, 28% lead, and \$2 in gold. After driving the adit for 2000 ft. the Empire vein was cut, and it was near the hanging wall that the strike was made.—The Hecla Mining Co. declared a dividend of 5c. per share, payable November 25 to stockholders of record November 5. This is a reduction of 10c. per share from the previous disbursement.

The second dividend of the Mammoth Mining Co. within one month was declared on November 4 amounting to 10c. per share and totalling \$40,000.—The shaft being sunk on the Eureka-Bullion property, under the direction of John Bestlemyer, is down 570 ft. and is progressing satisfactorily. Sinking has been hampered by the loose ground during the last 100 ft.—Electric power is now being supplied to the North Beck Mining Co. by the Utah Power Co., and the work of sinking the three-compartment shaft is progressing rapidly. The new company is operating under the direction of E. J. Raddatz. The machinery includes a 40-hp. compressor and a 25-hp. hoist, both electrically driven.—The ore shipments during the week ended November 10 totaled 120 cars as against 127 cars for the previous week. The mines are still greatly hampered for lack of transportation facilities and the output therefore is being materially curtailed. Following are the shippers:

	Cars
Dragon Consolidated .....	35
Iron Blossom .....	17
Centennial-Eureka .....	17
Mammoth .....	11
Chief Consolidated .....	10
Tintic Standard .....	5
Grand Central .....	5
Gold Chain .....	5
Eagle & Blue Bell.....	4
Empire Mines .....	3
Victoria .....	3
Gemini .....	3
Chief manganese lease.....	2
Ridge Valley .....	2
Bullion Beck .....	2
Sharp .....	2
Eureka Hill .....	1
Colorado Consolidated .....	1
Minnie Moore lease.....	1
Total .....	129

The Chief Con. earned 76c. per share for its stock in 1916 and closed the year with a \$477,295 surplus, or 54c. for each of the 884,000 outstanding shares. Its income for the year was \$1,391,869 and its operating expenses, including construction, \$719,766, leaving a net profit of \$672,103. The company paid \$176,481 in dividends, or 20c. per share, purchased the properties of four mining companies and other groups of claims adjoining its own ground, comprising altogether about 600 acres, for \$228,360, and added \$267,261 to its previous treasury surplus. Not more than 10 to 15% of the ground owned by the Chief company has been developed, and yet from its own workings more than \$3,000,000 worth of ore has been sold to the end of last year, approximately half of which was net profit. Since its organization the company has paid \$562,000 in dividends, invested more than \$400,000 in additions to its mining property, and put \$130,000 into equipment, besides accumulating \$477,295 cash surplus.

## MONTERREY, MEXICO

### NEW MINING LAWS.—REVOLUTIONARY OPERATIONS DELAY MINING.

According to advices received by mine-owners in Mexico, the Federal Government, through the Department of Fomento, is drafting a new mining law. It is stated that the measure will differ in many material respects from the existing act and that it will not contain some of the drastic decrees that have been promulgated by President Carranza. The tax on mining properties will be reduced and the oppressive restrictions that have operated to the detriment of many foreign mine-owners will be removed. The drafting of the new bill will be finished soon and submitted to Congress for enactment into law.—The revival of revolutionary and brigandage operations in different parts of the country is serving to cause further postponement of the plans that were on foot for the re-opening of various mines. It is stated that conditions in the State of Chihuahua have grown steadily worse during the last two or three weeks, due to the re-entrance of Francisco Villa into the military field. A number of bands of armed men claiming to be followers of Villa are operating in the vicinity of Parral, Santa Barbara, and other mining districts not only of the State of Chihuahua, but also in those of Durango and Zacatecas. Several independent bandit leaders have sprung up in different parts of the country and are making it again unsafe for mining men to attempt to resume work upon their respective properties. Railroad traffic is also much disturbed by reason of this renewal of activity on the part of armed opponents of the existing Government.

American and other foreigners who own mines in the State of Chihuahua were recently served with official notice by General Francisco Murgia, the military commander of that State, that if they do not resume the operations without further delay, their properties will be confiscated by the Government and turned over to Mexican laborers, who have been employed in them.

## COBALT, ONTARIO

### CHAMBERS FERLAND.—McKINLEY-DARRAGH.—HOLLINGER CON.

It is probable that the value of the silver production at Cobalt for the current year will approximate \$16,000,000 and, with the exception of 1912, when the value of the production was \$17,408,935, will be the highest in the history of the camp.

At the lower workings of the Chambers Ferland mine development and exploration will be commenced at once. This company has an extensive area in which little exploration work has been done. It has \$200,000 on hand and in British government war bonds and about \$100,000 in bullion.—The McKinley-Darragh is understood to be yielding approximately 75,000 oz. of silver per month. The favorable development at the 400-ft. level has added materially to the life of the mine.—Encouraging results are being obtained in the 310-ft. level at the Adanac where driving toward the north is going on. The vein maintains a width of about five inches and contains good-grade ore, the best of which is being bagged.—The Nipissing is maintaining production at the rate of about 10,000 oz. per day.

The improvement in the labor market at Porcupine continues, although nothing like pre-war efficiency is being obtained. The production of approximately \$750,000 per month from the camp under existing conditions plainly illustrates what may be expected when things become normal again.—The Hollinger Consolidated and the McIntyre-Porcupine alone are understood to be turning out upward of \$500,000 per month, and the Schumacher is producing at the rate of about \$35,000 per month.—The tendency throughout Porcupine camp is to devote energy toward development. Ore-reserves are being built up considerably in excess of production which would appear to point toward increasing prosperity.

# THE MINING SUMMARY

## ALASKA

(Special Correspondence.)—D. C. Stapleton, superintendent of the Gypsum mine, has recently purchased a boiler and pumps from the Treadwell company. The machinery will be erected at Gypsum, and an effort made to pump the mine free from water. Several weeks ago the large leak, which has been a source of trouble for years, broke out again and the property was flooded.—Development work on the Red Diamond group of claims, under option to the Treadwell company, has been discontinued.—Train service on the newly-constructed trestle went into effect today. R. G. Wayland, superintendent for the Alaska Treadwell company, is examining mining property in the vicinity of Wrangel.

Treadwell, October 22.

(Special Correspondence.)—Advices from the Land & Industrial Department of the Alaskan Engineering Commission are to the effect that machinery is on the way from San Francisco to operate leasing units No. 10 and 11 in the Matanuska coalfield, consisting of 1440 acres, near Chickaloon, leased to Lars Nelland, of Oakland, California. Two cars of coal from Chickaloon reached Anchorage last week. This coal was from Unit 12, consisting of 480 acres on the Chickaloon river, which was withdrawn by an executive order of June 17, 1917, for the Alaskan Engineering Commission, to furnish coal for the construction of the Government railroad. The coal tested by the navy in 1914 was from this unit and the completion of the railroad to, and transportation of coal from, this point is accomplishing one of the foremost purposes for which the railroad is being constructed. During the construction of the railroad to Chickaloon, the Commission used coal from the lower Matanuska field on Moose creek, some 40,000 tons having been shipped from there to Anchorage. The mines in the Willow Creek district have closed for the winter.

The Alaskan Engineering Commission's dredge 'Sperm' has been put into winter quarters after having been assembled and successfully tested in the mouth of Ship creek, where it will operate in the spring. The hull, a converted whaler, is 140 ft. long, 41 ft. beam,  $7\frac{1}{2}$  ft. depth of hold, and draws a trifle over 4 ft. of water. The ladder well is 20 ft. wide and 40 ft. long. The ladder is 100 ft. long, built of wood, and will dig at a depth of 70 ft. This great depth was made necessary because of the extremely high tide on Knik Arm, the maximum being over 34 ft. Power is furnished by coal under two Scotch marine boilers of 250 hp. each. The main engine is a compound-condensing, rated at 750 hp., built by the Ideal Engine Works of Springfield, Illinois. The centrifugal pump has 18-in. suction and discharge, and is 96 in. diam. There is a 5-drum hoisting-engine; feed, condenser, and underwriters' pumps, electric light plant, and steam capstans. The spuds are 100 ft. long, of Washington fir. The digging-ladder is equipped with a cutter specially designed to work in the tenacious glacial silt, which has built up the delta at the mouth of Ship creek. All the machinery, excepting this cutter, and the main engine, was built by the Willamette Iron Works of Portland, Oregon, and was formerly in use on a dredge owned by the Portland, Spokane & Southern railroad, and wrecked in a storm off Cape Flattery in the winter of 1916. The machinery was salvaged and the present dredge is the design of William Gerig, and has been erected under

his supervision. It has a rated capacity of 6000 cu. yd. per day, and will be used to dig a channel from the present ship anchorage and a harbor which will occupy the silted flat and tortuous channel at the mouth of Ship creek.

Anchorage, November 2.

Willow Creek mines have made only a light production for the season. There is much new development.

The Hercules Mining Co. is developing a molybdenum deposit on Reid creek. Both the sulphide and oxide of molybdenum occur in quartz and diorite.

G. C. Martin, of the United States Geological Survey, who recently reached Fairbanks from the lignite coalfields, 57 miles south of Nenana, said he had completed investigations preparatory to offering the lands for lease. Dr. Martin stated that

THE 'SPERM'

this work is supplementary to the survey of the main part of the coalfields, which was finished last year. At that time the coal on the west bank of the Nenana river was not examined, but this has now been done. The leasing offer of the mining units as provided by law will soon be made, for after the survey of the general land office the law requires that the land be divided into blocks best suited for economical mining. The coal lands in the Bering River and Matanuska districts have already been offered for lease in this manner.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—Machinery for sinking the 70-ft. shaft of the Arizona Bisbee Copper Co. is being hauled to the mine. Walter H. Weed has reported on the property. Until recently this company has been a close corporation, but now shares are being placed on the market to raise money to carry on development. Ample water has been piped to the property.—The Copper Chief Mining Co. is preparing to commence operations. A large compound compressor and hoist have been erected. Prior to closing down last January this company shipped two carloads of ore per day.—Some promising ore has been opened up recently on the lower levels of the Denn Arizona Copper Company.

Bisbee, November 10.

## GILA COUNTY

(Special Correspondence.)—The management of the Globe Dominion Copper Co. has decided to continue sinking its two-compartment shaft, which is now down 800 ft., to the 950-ft. level before cross-cutting. This property adjoins the Old Dominion on the east and south, and consists of some 25 claims. Considerable machinery and surface equipment is already in place.

Globe, November 9.

## MOHAVE COUNTY

(Special Correspondence.)—It is reported that the New Mohawk has again opened up a rich streak of silver ore.—The Tennessee has opened up a large body of ore on the 1170-ft. level.—The Henry Gold Mining Co. has been re-organized and has made its stock assessable in order to raise money to commence development work.—The United Eastern has added a heating system in the mill, so the production will not be curtailed during the winter. A splendid body of gold-silver-lead ore is being opened on the 800-ft. level of the Schuylkill. A shipment of 500 tons will be made shortly for experimental treatment at Needles.—It is reported that the Hill Top Metal Mines Co. has made a big strike in its upper workings.

Kingman, November 10.

## PIMA COUNTY

(Special Correspondence.)—The Whitcomb property in the San Xavier district, which consists of the Wedge group and the Prosperity, has been purchased under option by the Magnate Copper Co.—An extensive deposit of tungsten ore has been discovered in some old gold workings near Ajo.—The Daily Arizona Consolidated Copper Co. has been re-organized and sufficient money raised to develop the orebodies on the Copper Princess claim. Recent developments have blocked out about 75,000 tons of ore and shipping is in progress.

Tucson, November 10.

## PINAL COUNTY

(Special Correspondence.)—A rich strike of copper carbonate ore has been made in the 300-ft. level of the Queen Creek Copper Company.

Florence, November 9.

## SANTA CRUZ COUNTY

One of the most important decisions that has been rendered in this State, for mining men, was handed by Judge O'Connor, of Nogales, recently, when he decided that the \$8000 worth of tungsten ore, which had been re-plevined by Barry & Barry of Nogales and Boyle & Pickett of Douglas, attorneys for the N. A. Hart interests, was the property of Mr. Hart and his associates, of whom J. S. Douglas of Douglas is one. The ore in question was re-plevined from Wells Fargo company, who accepted it from ore dealers of Nogales for shipment. Systematic stealing of high-grade tungsten ore from the La Cruz mine, at Sonora, has been going on for the past two years, and all attempts to detect the thief or to recover any of the ore have been of no avail until the settlement of the case before Judge O'Connor.

## YAVAPAI COUNTY

(Special Correspondence.)—A two-foot vein of chalcopryrite assaying 9% copper, 1.5 oz. silver, and \$1.20 gold has been cut on the Cherry claim of the Green Monster Mining Co.—Work has commenced on the main drift of the Crown King. The drift is to be extended another 100 ft.—The Arizona Copper Queen Co. has commenced shipping to the Humboldt smelter.—The Yellow Jacket and Empire groups of gold claims in the Groom Creek section have been taken over by St. Louis capitalists and development work has been started.

Prescott, November 10.

## CALIFORNIA

## ELDORADO COUNTY

A 60-ton mill is being built at Stockton to the design of Burr Evans for the Cincinnati mine. The mill has several novel features, the crushing being done by eight 15-in. chilled-iron balls rotating on a grooved tread in a five-foot pan. It will be worked by an oil engine.

## NEVADA COUNTY

The North Star Mines Co. is preparing to put a full force of men at work underground in the Champion mines on Deer creek. The work of re-building the 40-stamp mill has been completed, and it will be kept running to capacity. Not only have the 40 stamps and equipment been entirely overhauled and re-built, but a concrete concentrating floor has been finished and the cyanide plant has been enlarged.

Ostrom & Co. has run an adit 600 ft. long into the hillside to tap the gravel-channel and has struck it several feet below bedrock. The gravel shows free gold, but the adit is being driven ahead to a point where it is expected that better ore will be found. As soon as the winter rains set in the washing of gravel will be started, and it is expected that it will be continued all winter.

## PLUMAS COUNTY

(Special Correspondence.)—The Walker Copper Co. has arranged to erect a Marcy ball-mill and other equipment which will increase the capacity of its flotation-plant from 75 to 200 tons per day. All equipment is now electrically operated. The sinking of a 340-ft. incline shaft has been started from the third level, the shaft being sunk at an angle to escape a water-pocket disclosed by the core-drills. The shaft is designed to open a new section of the mine and will carry development well within the sulphide zone. V. A. Hart is manager.—Norris & Noyes of San Francisco are developing an extensive chrome deposit near Swayne and shipping a carload per day to Niagara Falls. The ore is of excellent grade and the deposit is one of the largest yet discovered in California. Motor trucks are employed to haul ore from the mine to Swayne.—The development of manganese deposits in the Crystal Lake district and near Indian Falls is proceeding steadily, and several companies are making occasional shipments to the electric smelter at Heroult. Most of the ore under development is of excellent grade.—Development has begun at the Juneday group of gold claims, near Crescent Mills, under management of F. D. Searight. The old adit has been thoroughly repaired and opening of new ground started. Good ore is reported to be showing in the drifts.—The Uncle Sammie Mining Co., composed of Oakland people, has started preliminary work on a group of copper claims near the Engels mine. Good ore has been found near surface.

Portola, November 19.

## SIERRA COUNTY

The Dolan Bros. and A. G. Bell have closed their mine on Rock creek. A considerable amount of development has been done during the year, and there is a quantity of rock broken and ready for crushing in the spring.

## SISKIYOU COUNTY

(Special Correspondence.)—L. M. Prindle and H. G. Ferguson, of the U. S. Geological Survey, and C. A. Logan, of the State Mining Bureau, spent several months the past fall examining the platinum deposits in Siskiyou county. They have awakened the placer miners to the appreciation of the value of the metal and extra efforts will be exerted toward its recovery in the future.

F. B. Hall of Reno, Nevada, has purchased the Simas quartz mine in the Greenhorn district and will begin operation soon.—Wike & Mathis of Sawyers Bar have purchased the George D. Carter placer mine, five miles below Sawyer Bar. The mine

is fully equipped for operation.—A. E. Dench of Seattle has taken a lease on the Osgood placer mine, near Yreka, and is equipping it with a large force of men.—Theodore Knackstedt of Etna will operate the Bloomer placer mine near the Forks of Salmon during the coming season.—John Boyle is operating the Home Stake mine in the Etna district; he reports a satisfactory clean-up from the last run.—Cleveland Barry of Etna has taken charge of the Bonally mine.

Hornbrook, November 16.

(Special Correspondence.)—The Grey Eagle Copper Co. has 50 men at work and has provided quarters for 30 more. Additional air-drills have been purchased; all underground work is being done by contract. William Korner is manager.—Representatives of Eastern capital are examining large low-grade gold deposits in this county, including a property recently opened by W. P. Fisher of Humboldt.—Alex MacCartney and associates of Seattle are developing the Taylor Lake group of gold claims above Etna Mills. So satisfactory has recent work been that the operators are making preparations for development along broader lines, and have shipped in a large quantity of supplies.—The old Pilot Knob group, near Gottville, is reported to be developing well. Work has been in progress several years, and a large tonnage of medium-grade gold ore has been blocked out. A five-stamp mill is running steadily and a gasoline engine has been erected to furnish power. T. K. Anderson is managing owner.

Etna Mills, November 19.

As the great dam of the California-Oregon Power Co. across the Klamath river at Copco, 45 miles from Klamath Falls, is completed, the tunnel which carried the waters of the stream during the construction period was closed on November 13, and the immense reservoir formed in the channel of the river by the dam is filling with water. It will require nearly four weeks to fill the reservoir, which stretches up-stream for five miles. The bed of the river was excavated to a depth of 125 ft. to get a solid foundation for the great weight of masonry and reinforced concrete in the large dam, which rises to a height of 125 ft. above the bed of the Klamath river. The dam is 95 ft. wide at the base and 500 ft. long, and the cost of the work will exceed \$1,500,000. For three years over 300 men worked on the project. The company plans to generate 26,000 hp. under present conditions, and an equal amount can be developed by the addition of other units to the power plant.

#### YUBA COUNTY

The new \$500,000 dredge, No. 17, was launched at Hammon-ton on November 4. Fully 500 people from Marysville and this vicinity were present to witness the launching of the big steel dredge, which is one of the largest in the world. The dredge, which will be put to work immediately, was built by the Yuba Manufacturing Co. of Marysville, under the supervision of Paul E. Morse. It was built for the Yuba Consolidated Gold Field Company.

#### COLORADO

##### BOULDER COUNTY

(Special Correspondence.)—W. S. Harpel, superintendent for the Consolidated Leasing Co. west of the Huron, has a force of men at work on the new mill, which is being pushed as rapidly as possible.—J. A. Wilson has opened up a big body of high-grade ore in the Lost Lake mine near Eldora.—A. B. Clarkson of St. Louis and H. C. Newton and Otto Victor of Eldora, have exposed a vein on the Lone Pine lode in the Caribou district. The property is in the vicinity of the Boulder County mine.—The Up-to-Date mines at Caribou are producing a high-grade ore from the shoot recently opened in the adit.

Eldora, November 10.

##### TELLER COUNTY

The Ella W., on Tenderfoot hill, is the scene of a new dis-

covery made by Johnstone and Tomkins, who two years ago opened up the first ore on the claim and sold their lease for a good round sum. The prospectors have made their latest discovery on the south end of the Ella W. and from shallow trench workings have taken out between 15 and 20 tons of ore assaying two ounces in gold per ton. The property is owned by the Gumaer estate.—The north 400 ft. of the Wilson mine of the Free Coinage Gold Mining Co., on Bull hill, has been leased by the Free Coinage Consolidated Mines Co., holding control of the first-named corporation, to Leon F. Le Brun, of Cripple Creek, a miner who some years ago operated on the same ground. The lease runs for a two-year term and the lessee, who is already mining milling-grade ore, will pay a graded scale of royalties on ores marketed. A meeting of the shareholders of the Free Coinage Gold Mining Co. will be held at the company's office at South Altman, on December 15 for the purpose of electing three directors.—The Excelsior Mining & Milling Co., F. O. Wiborg of New York president, holding a long-time lease on the Longfellow mine of the Stratton estate, is constructing a new, up-to-date, steam-heated ore-house, and erecting a seven-drill Imperial Rand compressor. E. J. O'Flaherty, the superintendent, has just finished sinking the shaft to the 600-ft. point and will drive for connection with the Golden Cycle mine workings, extended into the Longfellow, where a good grade of ore is exposed in both the 500 and 600-ft. levels.—The mill of the Rex Mining & Milling Co., on Ironclad hill, will be closed down for the winter months as soon as the clean-up now in progress by Thomas Kavanaugh is completed. The Rex mill, operating under lease, has during the past year treated approximately 8500 tons of ore. This ore is quarried out from the hillside.—The high cost of mining supplies is reducing materially the number of miners employed on leased properties.

Cripple Creek, November 16.

Richard Roelof, general manager for the Cresson Consolidated Gold Mining & Milling Co., reports an ore-reserve of \$3,652,562 on August 1, as against \$4,130,318 on the same date in 1916. During the year 191,384 tons has been shipped, yielding \$2,359,663.88 net.

#### IDAHO

##### SHOSHONE COUNTY

Several stringers of high-grade copper ore were encountered recently in the lower adit of the Big Creek Mining Co. The adit lacks 50 ft. of a point under the upper workings where it is expected the lode will be cut. The lower adit has reached a point 2300 ft. from its portal and several hundred feet below a point in the upper workings from which shipments of high-grade ore have been made. The work is being directed by G. Scott Anderson.

#### MISSOURI

##### JASPER COUNTY

The new 150-ton mill on the property of the N. J. & B. Co., north of Duenweg, was started on November 12. James H. Johnston, of Carthage, is manager and one of the principal stockholders. The property has been exclusively drilled and some promising ore has been found.

#### MONTANA

##### SILVER BOW COUNTY

(Special Correspondence.)—The week ended November 3 showed a remarkably steady increase in the production and in the number of men employed in the Butte mines. The Anaconda company is hoisting an average of 12,000 tons of ore per day and has more than 8500 men on its payroll in this district. These figures show that the company is now employing more than 80% of its normal crew. Men are returning to the mines so rapidly that plans are under way to open

two large properties now undergoing repairs. A great many men are returning from small properties that have closed down for the winter. Owing to the fact that this district has given up over 2000 men for federal service, and that 1650 more men have left for unknown reasons, it is considered that the mining companies are doing wonderfully well.—The increase shown by the other operators, namely, Butte & Superior, Clark interests, East Butte, and Davis Daly, is in the same proportion as the Anaconda company. The North Butte Mining Co. is confining most of its efforts to the repair work at the Granite Mountain shaft.

Butte, November 1.

A dividend of 10c. per share was paid by the Barnes-King Development Co. on November 15, amounting to \$40,000. This is the third dividend declared by the company, the others being in March 1916, \$30,000, and in June 1916, \$30,000, making a total of \$100,000.

## NEVADA

### MINERAL COUNTY

(Special Correspondence.)—The Nevada Rand mine has started shipments to the Hazen sample-works, the initial consignment averaging \$77 per ton in silver and gold. The shipping ore is taken from the new vein on the 180-ft. level, where four to seven feet of ore is being broken in the stope. Driving from the 450-ft. level is being pressed to cut the new vein and open the main orebody, which has been tapped on the 150, 180, and 250-ft. levels. S. E. Montgomery recently stated the reserve contained 35,000 tons of ore.—The Copper Mountain Co., controlled by the Jumbo Extension Co. of Goldfield, has purchased the Miller-La Patt lease and resumed shipments. Ore of shipping grade is reported in bottoms of shafts No. 1 and 2, and No. 3 is being sunk rapidly to the ore-zone. The management states that sufficient ore has been developed to warrant erection of a small concentrator. It is probable the company will be re-organized on an assessable basis.—The Mogul Mining Co., operating at Rawhide, has arranged to sink its 3000-ft. shaft an additional 700 ft. It is stated that a six-foot vein has been opened on the 300-ft. level, assaying \$9.80 per ton, the discovery being made on the Regent claim.—Heavy shipments of copper ore are going to custom smelters from properties near Mina, and several new mines are nearing the productive stage. The Ray Consolidated recently entered the shipping list.

Mina, November 20.

(Special Correspondence.)—The Pilot Copper Co. at Luning is taking out 18 tons of 5% copper ore per day from the Anderson group.—With the blowing-in of the second unit of the Thomson smelter, the Kirchen Mines Corporation expects a demand for the big body of iron ore, carrying a small proportion of copper, which is near the surface of the St. Patrick mine. Heavy shipments of this ore were made last spring but were discontinued when the smelter ran short of coke. Regular shipments of high-grade ore are made from the St. Patrick.—The last three samples assayed from the bottom of the Siri shaft of the Wedge Copper Co. returned \$17.37, \$23.50, and \$14.81, respectively, per ton. Good progress is being made by the contractor on the No. 2 adit which opens the vein 200 ft. below the No. 1.—The second carload of silver ore went out from the R. B. Todd mine last week and a carload of copper ore will go from the Luning-Idaho mine next week.—The Congress Copper Co. is confining most of its efforts to development work.

Luning, November 13.

## NEW MEXICO

### QUAY COUNTY

(Special Correspondence.)—A deposit of potash has been discovered upon the property of Red Peaks Copper Co. near Tucumcari. Arrangements are being made by the company

to start development and to erect the necessary plant for extracting the mineral.

Tucumcari, November 12.

### SOCORRO COUNTY

(Special Correspondence.)—A large gang of workmen are re-timbering the upper section of Little Fanny shaft. In the meantime miners are using the Little Charlie entrance. The Socorro company has taken over the saw-mill of the Mogollon Lumber Co., has put on its own men, and is getting out timber for re-building the head-frame and upper portion of the mill recently destroyed by fire. A 2100-lb. clean-up was made during the week. The Mogollon Mines Co. has been running its mill to full capacity and steadily increasing the ore-reserve. About 3000 lb. of gold and silver was sent to mint during October.

The Oaks Co. is maintaining regular daily shipments from

NEW MEXICO

its Central group. The Maud S., Deep Down, Clifton, and Eberle mines are all being developed and shipments are being made regularly from each.

Mogollon, November 13.

## OKLAHOMA

### OTTAWA COUNTY

Good results have been obtained by drilling on the Thomas land, four miles south-west of Baxter Springs on the Oklahoma side. The fourth hole drilled on the lease showed a 112-ft. orebody. In this hole ore was found at the 48-ft. level and continued to the 160-ft. Assays of the borings between the 56 and 72-ft. level ran from 42 to 56% zinc and 7 to 17% lead.

Two separate mills are being built by the Hawkins Lead & Zinc Co. on the site of the old Lancaster mine, at Sunnyside, one mile east of Lincolnville. One is a regular mill of 200 tons capacity, while the other is a modern tailing-mill, which will be used to work over the big tailing-pile left by the original Lancaster plant, which was burned down some years ago. The plants are both strictly modern and will be equipped with oil engines. In the tailing-mill there will be high-speed Cornish rolls for re-grinding. The company intends to work the level that was opened ten years ago by the original company, and also to sink to a deeper level.

If plans do not go awry construction work on a new 800-ton mill of the Brown & Head Zinc Co., with headquarters at Joplin, will begin within two weeks on a lease of the Cooper land situated on the Kansas side north-west of Picher. It was planned to begin building the mill in October, but delay in obtaining building material and machinery made it necessary to postpone the work. Shaft-sinking is being carried on; both shafts are down near the ore-level. An almost uniform ore-body was shown from 175 to 255-ft. levels; 25 drill-holes were sunk on the lease before shaft-sinking was begun. The company's lease is situated just south-east of the new 800-ton mill of the United States Smelting company. J. E. Head, of Tulsa, is chief owner of the property. Don D. Molloy, of Joplin, and W. W. Marsh, of Webb City, are in charge of field operations.

A company of Texas and Oklahoma capitalists has purchased the concentrating plants of the St. Louis Smelting & Refining Co. and the lease of the 160-acre tract on which they were situated and additional leases on 1240 acres, immediately to the east, in the heart of the Missouri-Kansas-Oklahoma zinc-lead district. The two concentrating plants are the largest and best equipped in the district. Extensive drilling has been done on a large part of the acreage purchased, which, it is said, has proved an immense orebody running from Century in a north-easterly direction toward Baxter. Among the capitalists interested in the purchase are C. C. Slaughter, head of the Slaughter cattle interests in Texas, Walter Morris and L. P. Gamble of Dallas, and O. D. Halsell of Oklahoma.—R. P. Sharp of Miami and H. M. Ferguson and associates of Mangum, Oklahoma, have purchased the Sambo mine at Lincolnville from the National Bank of Commerce of St. Louis for \$150,000. The property consists of a 40-acre well-developed lease and a 300-ton concentrating plant. Recent operations have proved an orebody of 75 by 100 ft. The new owners will increase the mill to 500 tons capacity. Another mill is to be built on the lease of the Buffalo Mining Co. The No. 1 mill is situated at Quapaw and has been in operation for only a short time. The No. 2 mill will be built on the Red Skin lease in Kansas to the west of the property of the Blue Mound Mining Company.

## TEXAS

### HUDSPETH COUNTY

(Special Correspondence).—The Sierra Blanca Mining Co., which has a capital stock of \$1,000,000, has begun the development of its mine seven miles west of Sierra Blanca. The ore from the present workings runs more than 14 oz. silver and 52% lead per ton. The stock of this company is owned principally by William W. Crosby of Eagle Pass, and J. W. Atkins of Shreveport, Louisiana. Several other promising prospects in the same section of the Quitman mountains where this mine is situated are being developed. Regular ore shipments are being made from some of the properties and plans are on foot for the building of one or more ore-reduction mills. It is stated that besides silver and lead, some of the ores contain gold, zinc, and copper.

Sierra Blanca, November 14.

## UTAH

The report of the Chief Consolidated, covering the period from July 1 to September 30, shows 13,075 tons dry ore mined, yielding, after smelting, transportation, and sampling charges were deducted, a total of \$414,850. The net profits, after paying all charges, was \$69,041 for the three months. The report shows \$478,566 cash on hand. The total development work was 5098 ft. This includes 579 ft. at Pinyon Peak and 584 ft. in the Plutus. The metal content of the ore mined was as follows: Gold, 2458 oz.; silver 382,302 oz.; lead, 2,033,587 lb.; and zinc, 194,508 lb. The assays of the ore were 0.188 oz. gold per ton, 29.28 oz. silver, 10.86% lead in lead ores, and 36.29% zinc in zinc ores. The average gross value was \$45.98 per

ton. The smelting, freight, and sampling-cost was \$14.25 per ton, leaving an average net of \$31.73 per ton. The dry tons mined are classified as 9592 lead, 3215 other ore, and 268 tons zinc ore, a total of 13,075 tons.

### SALT LAKE COUNTY

The Utah Metals Co. has declared a dividend of 30c. per share, payable December 10 to stockholders of record November 30. This means a payment of \$207,476 on the company's outstanding stock of 691,588 shares and swells its dividend total to \$892,598. It is the second dividend declared this year and is a reduction of 20c. per share in the amount distributed last February, when the company paid 50c. As is generally known the Utah Metals Co. operates at Bingham, where it controls nearly 4000 acres of valuable ore-bearing ground. In the year ended December 31, 1916, the company produced 6,301,670 lb. of lead, 1,761,520 lb. of copper, 388,757 oz. of silver, and 17,934 oz. of gold, from which it earned a net profit of \$528,737. Its possessions include the ground formerly owned by the Bingham-New Haven Copper & Gold Mining Co., equipped with a concentrating plant, and it has several large orebodies which are said to warrant a heavy production for years to come. The company paid its first dividend of 50c. in August 1916.

## WASHINGTON

### FERRY COUNTY

The shipments of the Knob Hill company totaled 500 tons in October, according to John Byrne, president, who has concluded an inspection of the property. The net smelter returns, mainly for gold, averaged more than \$400 per car of 40 tons. The greater part of this ore came from above the main adit, but the shaft-workings, where development has been started, contributed in a small way. Ore was reached on the 200-ft. level of the shaft-workings soon after a drift was started from the cross-cut. It was lost for awhile, but found again at 135 ft. The body has a width of 5 to 24 in. and contains \$5 to \$58 per ton. A raise will be made to connect with a 130-ft. winze, sunk from the adit, as soon as the winze is freed of water. The ascent will be about 100 feet.

### KING COUNTY

Formal announcement was made on November 16 that the plant of a newly-organized steel manufacturing company, financed for the greater part by California capitalists, will be built on Puget Sound and that work will soon begin on the first unit, requiring an investment of \$9,000,000. The full development of the project will require \$25,000,000. The announcement was made by Bartlett L. Thane, general manager for the Alaska Gastineau Mining Co., who is now at Seattle. Associated in the project are W. H. Crocker, Herbert Fleishacker, S. F. B. Morse, and other San Franciscans. Eighty per cent of the money for the beginning of the work has been subscribed in California, most of it in San Francisco. It is expected that the plant will be in operation within a year and a half.

### STEVENS COUNTY

The Northwest Magnesite Co. produced 19,000 tons of magnesite in October, of which 13,000 tons was calcined; the remainder was shipped in the crude form and placed in reserve at the plant near Chewelah. The shipments of calcined magnesite averaged 180 tons per day in October and is proceeding at the same rate this month. The building of a calcining plant and of a tramway are nearing completion. Two of the metal kilns, each about 130 ft. long, have been in operation many weeks and the third will be in commission by December 1. The tramway, which is to be five and one-half miles long, will be completed about the same time. The cost of this and other equipment and of improving the property otherwise was estimated at \$250,000 when work was started

several months ago. The freight charges for the movement of magnesite are about \$100,000 per month. R. S. Talbot, president of the company, has returned from the East.

The Thorp Iron Co. has bought material for the construction of two brick kilns to be used in calcining magnesite on its property, 14 miles west of Valley. The company has nine claims in the magnesite belt. Part of the group gives promise of a yield of iron, for which it was acquired. The property is a mile or two from a railroad in process of construction from Valley.

### MEXICO

According to G. M. Seguin, Mexican consul general at El Paso, the Alvarado Mining & Milling Co. has resumed operation of its Parral properties. Four hundred men are working and this force will soon be doubled. The San Francisco del Oro corporation, a British syndicate, with offices in New York, has also partly resumed operation of its property. Twelve carloads of mining machinery were shipped through the Juarez port to this corporation on November 6 and will be transported to its properties in the Parral district. This company expects to have fully 500 men employed in the Parral district within the next 10 days. Preparations are being made by the American Mines & Smelter Co. to resume the operation of mines in the Magistral, Durango district. The American Smelting & Refining Co. expects soon to finish the construction of its smelter at Chihuahua. Mr. Seguin said that General Francisco Murguía had promised to give protection to all mining corporations that resume operation. He has sent detachments of troops to the Alvarado and San Francisco del Oro properties in the Parral district.

According to the Boletín Financiero y Minero de Mexico, of October 10, the International Ore Co. of Saltillo, State of Coahuila, is constructing two furnaces, each one containing 300 retorts, with a capacity of approximately 40 to 45 tons per day and a daily production of zinc amounting to 15 tons. The furnaces will burn crude petroleum and the waste gases will be used under the boilers. The cost of this project is estimated at \$90,000 American currency.

## Water and Mines in Paradise

In our issue of November 3, we published a letter from Mr. J. D. Hubbard, on 'Water and Mines in Paradise.' An error of punctuation appeared in the sentence: "How about the Mineral Slide Mining Co. in Sec. 10, T. 23 N., R. 3 E., M.D.M. Mr. Goodner not only protested, but forced withdrawal of their property from the irrigation district." This statement should read: "How about the Mineral Slide Mining Co. in Sec. 10, T. 23 N., R. 3 E., M.D.M., Mr. Goodner? They not only protested, but forced withdrawal of their property from the irrigation district."

At the annual meeting of the WESTERN METALLURGICAL AND CHEMICAL SOCIETY, held at Chicago, October 1 to 3, Baron C. B. Smith, London, was elected president; R. H. Burgess, Chicago, vice-president; John M. Meyerburg, Oakland, treasurer; and Roy Franklin Heath, Billings, Montana, secretary. A reorganization of the society was announced by the chairman. An annual and a quarterly bulletin will be published by the society. The clause restricting the membership to 200 was eliminated from the by-laws, while the initiation fee was reduced from \$50 to \$15. The yearly membership dues were reduced from \$25 to \$10. A resolution was adopted unanimously, urging President Wilson to use every effort and power within his reach to defeat "the Prussian chief and his powder gang." A committee was appointed by Mr. Smith to undertake an investigation regarding professional ethics. Reports covering the various departments were read and discussed.

## PERSONAL

*ote: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

GEORGE S. BUTTERWORTH has returned to New York from Venezuela.

G. BROKENSHIRE has enlisted in the Engineering Corps of the U. S. Army.

E. A. JULIAN, of the Goldfield Consolidated, has returned from New York.

BERNARD MACDONALD has returned from Antofagasta, Chile, to South Pasadena, California.

FREDERICK BRADSHAW, manager for the Tonopah-Belmont Development Co., is in Colorado.

G. W. LAURIE, of the firm of Drucker & Laurie, New York, has joined the 23rd U. S. Engineers.

BENJAMIN REZAS has gone to the Philippine Islands to join the staff of the Colorado Mining Company.

G. A. JOSLIN has returned to Salt Lake City, having spent the summer in the Bay Horse district, Idaho.

FRITZ MELLA has resigned from the employ of the A. S. & R. Co. and is now on his way to Santiago, Chile.

J. L. PHILLIPS, formerly manager of the Inguaran mine, in Mexico, was here from Los Angeles during the week.

L. R. DAVIS, from Wyoming, and R. V. AGERTON, from Butte, are commissioned in the engineer section of the Air Service.

W. C. WEBSTER, secretary and general manager for the Nichols Copper Co., New York, has resigned, and expects to take a rest.

BEN. B. THAYER, having recovered from a recent illness, has gone to Butte on his periodical trip of inspection from the Anaconda Copper Company.

## Obituary

LEO VON ROSENBERG, Baron Leo Franz Serafinus Georg Orsini Von Rosenberg Lipinsky, was born on June 29, 1858, at Klagenfurt, Austria. He died at New York on October 6, 1917. He received his education in the best schools in Austria and at Freiberg. Coming to the United States with his father in the early 'eighties he shortened his name to Von Rosenberg, by which he was thereafter known. His first work in this country was as a draftsman. Most of the illustrations in the important book on 'Tunneling,' by H. S. Drinker, were prepared by him. In 1887 he published a book on the Vosburg tunnel, profusely illustrated and giving a complete description of the construction of that important work. Later he published a work on the Musconetcong tunnel. His great work in publishing was 'The Washington Bridge'; probably no engineering work has been more thoroughly and accurately described and illustrated. At the time he was engaged upon this publication he also was occupied in preparing maps and reports for various mining companies. Many of these reports were printed in pamphlet form for distribution among the stockholders and others; and aside from intrinsic value were remarkable for artistic make-up. He practised as a consulting mining engineer and obtained an honorable reputation for such work. Among the mines upon which he either made reports or issued publications may be mentioned the Playa de l'Oro, Cerro de Pasco, Umbria, Russell, Osol Condo, Victor, Gold Coin, Vindicator, Fortuna, and Golden Cycle. An engaging and kindly man, he made many friends in the West and his death will cause wide-spread regret.

# THE METAL MARKET

## METAL PRICES

San Francisco, November 20

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (100 lbs.), per pound.....	\$0.95
Antimony, cents per pound.....	16.00
Antimony (wholesale), cents per pound.....	14.75
Electrolytic copper, cents per pound.....	23.50
Pig-lead, cents per pound.....	6.50—7.50
Platinum, soft and hard metal, respectively, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	100
Spelter, cents per pound.....	9.50
Tin, cents per pound.....	65
Zinc-dust, cents per pound.....	20

## ORE PRICES

San Francisco, November 20

Antimony, 45% metal, per unit.....	\$1.10
Chrome, 34 to 40%, free SiO <sub>2</sub> , limit 8%, f.o.b. California, per unit, according to grade.....	\$0.60—0.70
Chrome, 40% and over.....	\$0.70—0.80
Magnetite, crude, per ton.....	\$8.00—10.00

The demand for magnetite is confined almost entirely to the calcined product.

Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.

Tungsten, 60% WO<sub>3</sub>, per unit..... 30.00

Molybdenite, per unit MoS<sub>2</sub>..... \$40.00—45.00

## EASTERN METAL MARKET

(By wire from New York)

November 20.—Copper is unchanged and nominal at 23.50c. all week. Lead is quiet and firm at 6.50c. all week. Zinc is dull and steady at 7.87 to 8c. Platinum remains unchanged at \$105 for soft metal and \$111 for hard.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
Nov. 14.....	86.00
" 15.....	85.75
" 16.....	85.75
" 17.....	85.50
" 18 Sunday.....	85.50

May ....	18.71	29.02	31.69
June ....	19.75	27.47	32.67

Not until the current year have exports of copper in a single month run above 100,000,000 lb. In January clearances were 114,960,000 lb. August figures, just at hand, show that in that period there was shipped abroad from this country 101,129,000 lb. of copper, making the fifth month of

1917 in which the 100 million mark has been exceeded. Up to the first of September there had been shipped 778,380,561 lb. of copper, against 521,976,630 lb. in the same months last year and 433,205,804 lb. two years ago. In addition to these large copper tonnages the shipments of brass—two parts copper to one part spelter—have broken all previous records.

It is understood that the Anaconda Copper Mining Co. has been increasing its holdings in shares of the Inspiration Consolidated Copper Co. around the recent low prices. Anaconda has been carrying for some time 200,000 shares of Inspiration upon which it has been drawing dividends at rate of \$8 per share. During the past two years a strong surplus has been built up by Anaconda, and Wall Street believes a part of this has been invested in additional amounts of Inspiration stock. Both companies have managements closely allied, with John D. Ryan the dominant factor.

## ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Date	Average week ending
Nov. 14.....	7.87
" 15.....	8.00
" 16.....	8.00
" 17.....	8.00
" 18 Sunday.....	8.00
" 19.....	8.00
" 20.....	8.00

## Monthly Averages

	1915	1916	1917
Jan. ....	6.30	18.21	9.75
Feb. ....	9.05	19.99	10.45
Mch. ....	8.45	18.40	10.75
Apr. ....	9.78	18.62	10.20
May ....	17.03	16.01	9.41
June ....	22.20	12.85	9.63

Australia has ceased the shipment of zinc-bearing material to the United States, the movement having been diverted in great part to England where smelting facilities have been greatly enlarged during the past two years. Originally Australian product was sent to Belgian and French smelters controlled by German metal interests, but the outbreak of war altered this programme, and in the early days of the European struggle large quantities of zinc were brought to this country for treatment.

## QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date	Week ending
Oct. 23.....	100.00
" 30.....	100.00

## Monthly Averages

	1915	1916	1917
Jan. ....	61.90	222.00	81.00
Feb. ....	60.00	295.00	126.25
Mch. ....	78.00	219.00	113.75

May ....	39.28	49.10	63.21
June ....	40.26	42.07	61.93

Owning the only tin smelter in this country, the American Smelting & Refining Co. should, early in 1918, be in position to furnish from its New Jersey plant 800 tons of electrolytic tin monthly to consumers in the United States. Sufficient construction headway has now been made to offer assurance that by January the Guggenheim's tin smelter should be up to its capacity. In October the A. S. & R. Co. turned out about 600 tons of electrolytic tin, representing the only domestic production in the United States. This month's contribution should be about 650 tons. December's output 750 tons, while January is expected to show an 800-ton yield. The raw material for the smelter comes from Bolivia in the form of about 60% tin, which has to be reduced to marketable forms and shapes. Despite its richness in practically all minerals the United States has not yet produced a tin mine of value. In 1916 there was found but 278,000 lb. of tin in this country, against 204,000 lb. in 1915.

## MAGNESITE

Little business has been reported on magnesite, although the market remains practically the same.

## MANGANESE

The November schedule for furnace ore remains at \$1.20 per unit for high-grade material, which is an advance of about 10c. over last month's schedule.

# Eastern Metal Market

New York, November 14.

The markets are generally inactive, but fairly steady and firm. There is little incentive to buy under present conditions.

Copper is nominally unchanged at the Government price, with no line on actual conditions.

Tin has been soaring, reaching the highest price ever recorded, due to great scarcity.

Lead is quiet but firm and steady.

Zinc displays a better tone and is firmer.

Antimony is in poor demand and is nominally lower.

Aluminum is unchanged and dull.

The steel trade is adjusting itself to the new regime with less friction than was expected. New prices have again appeared, including bar-iron, boiler-tubes, nuts and bolts, boat-spikes, wire-rope, pipe, skelp, etc. Little finished steel is being sold for general commercial needs, most mills being booked for three to six months in advance. The Government's requirements for ship-plates will probably be 100% of ship-plate production. The pig-iron market is quite active, with most furnaces sold up through the first half of 1918.

## COPPER

The entire situation is 'up in the air' and shrouded in mystery so far as definite and authentic information is concerned. Whether sales for early delivery in large volume have been made to consumers having Government contracts at the Government price of 23.50c. per lb., or at any price, is not known, though statements are appearing in print to that effect. In the absence of facts we continue to quote the fixed price as nominal. There has been no illumination on the perplexing situation of the small dealer and buyer, but it is understood some sales in this field are being made at higher than the Government price. The market is absolutely uninteresting. Statistics as a rule are dry, but it is significant to note, as affecting the general situation, that copper exports for the first nine months of this year have been larger than for any whole year of 12 months on record. To October 1, the total is reported as 370,843 long tons as compared with 327,310 tons in the whole of 1916, and 360,229 tons in 1914.

## TIN

The scarcity of tin, spot Straits, Banca, and Chinese, is so great that prices have reached levels never before recorded. Yesterday spot Straits sold at 73.50c. per lb., New York, in a transaction involving 5 tons, and later another 5-ton lot was offered at 73c., New York. The market on Monday, November 5, was 68c., New York, as reported in our letter last week, but it has advanced continually since. On November 7 it was nominal at 71c., but sales were made at 70c. on both November 9 and 12, with the quotation standing at 73c., New York, yesterday. Another interesting feature was the Government's action yesterday. Failing to obtain any tin on an inquiry for 15 to 25 tons of spot Straits for the Washington Navy Yard, the required material was requisitioned from an incoming steamer which had 250 tons on board, already sold to consumers. What price will be paid has not been divulged. The stiff permit-requirements in England are the prime cause of the present scarcity because shipping-permits are issued only to consumers whose names are divulged, so that buyers of less than 25-ton lots are extremely anxious. On the whole the market is quiet and inactive, buyers abstaining as far as possible until the situation clears. On November 7 a sale of 25 tons of Eastern shipment in October was sold at 64.25c., and on November 8 shipment from the East at sellers' option in February, March, and April went at 61.25c.

Arrivals up to November 12 inclusive have been 830 tons, with 4100 tons reported afloat. The London market has had a large advance of £13 10s. in the week, spot Straits being quoted yesterday at £274 per ton.

The Tin Committee has been in Washington in the last week and while the result of the deliberations has not yet had any effect on the market, it is understood that an agreement has been reached, which is expected to relieve the situation.

## LEAD

The American Smelting & Refining Co. advanced its price again on Wednesday, November 7, from 6 to 6.25c. per lb., New York, while the outside market had already gone to 6.50c., New York, or 6.37½c., St. Louis. These prices are the present levels with transactions of small volume. This is natural as a result of the large purchasing of the last two or three weeks, noted a week ago. There is but one weak point in the situation which otherwise is strong and firm. It is the fact that there were a few sellers who abstained from the market in its recent large activity and who are consequently probably able to offer some metal at concessions. It is reported that lead has been offered in the last day or two at 6.35c., New York.

## ZINC

The prospect of large Government purchases of shells in the near future has imparted a better tone to the market, and it is firmer. One report is to the effect that the Government has purchased or is about to buy 33,000,000 shells of the 3-in. size. This will require 33,000,000 lb. of zinc for making the brass shell cases. It is true that meetings are being held jointly by the War Industries Board and the zinc producers, and definite announcement of plans is expected soon. It is generally thought that the question of price-fixing is being seriously considered with the probability of some definite levels to be agreed upon. While small lots of prime Western have been sold recently at anywhere from 7.50 to 7.87c. per lb., St. Louis, the lower prices have disappeared in the last day or two, and the market is quotable at 7.75c., St. Louis, or 8c., New York, with the market quiet but firm.

## ANTIMONY

The market is lower because of poor demand and large imports. Chinese and Japanese grades are quoted at 13.75 to 14c. per lb., New York, duty paid.

## ALUMINUM

There is no change, and the market is inactive and quiet at 36 to 38c. per lb., New York, for No. 1 virgin metal, 98 to 99% pure.

## ORES

Tungsten: One dealer reports that South American supplies are scarcer, due to restrictions resulting from the Trading with the Enemy Act. The usual quotation for the various grades of ore are firm, with a tendency to advance. Ferro-tungsten is obtainable at \$2.35 per lb. of contained tungsten.

Molybdenum: Molybdenite continues to be quoted at \$2.20 per lb. of MoS<sub>2</sub> in 90% material and some business has been done at this figure.

Antimony: The market is quiet and nominal at \$1.60 to \$1.75 per unit.

Chrome: The market for high-grade chrome ore remains practically the same with 90c. per unit quoted f.o.b. Californian shipping points. Chrome over 60% is scarce and practically all the shippers are mining a low-grade product.

# INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

## THE FIRST HEINE BOILER

After a fire which destroyed the National Guard Armory, at 18th and Pine streets, St. Louis, Missouri, a few months ago, the Heine Safety Boiler Co., of that city, obtained possession of the first Heine boiler ever built, which was installed at the armory in 1881. This little boiler is shown in Fig. 2, just as

since then, and until the time of its removal to your shop, where it is now located on blocks. The tubes are pitted, and before the boiler can be used, it will be necessary to re-tube it, also the blow-off flange should be renewed and the boiler completely provided with valves and trimmings if it is to be installed and used further. In the event of the boiler being installed, we could allow a working pressure of 80 lb. per

FIG. 1. TYPE OF MODERN HEINE WATER-TUBE BOILER

it was removed. It has 24 tubes about 10 ft. long and the heating surface is approximately 250 sq. ft., making a rating of the unit 25 hp. The boiler was built in the shop of Richard Garstang at St. Louis. The original pressure for which it was designed was about 100 lb., and an inspection-certificate from the Fidelity & Casualty Co. has been received to the effect that they will certify this boiler to carry 80 lb. pressure at the present time. The report of inspection is reproduced below:

"Heine Safety Boiler Co.,

"St. Louis, Missouri.

"Our inspector, Mr. W. A. Rutledge, made an internal inspection on July 24, 1917, of the first boiler of the Heine type built by the Heine Safety Boiler Co. The boiler was constructed about 35 years ago and has been in continuous service

square inch, after the above recommendations have been carried out.

"D. C. HARVEY, Superintendent."

This indicates a somewhat longer life for water-tube boilers than is usually credited them by accountants or engineers when apportioning depreciation charges. However, under modern conditions the heavier loads on boilers would perhaps tend to lessen their life as compared to this little boiler. One odd feature is the casting which forms both the steam-outlet and the water-column. Another obsolete feature is the vertical baffling which was discarded in later designs for the horizontal baffling, now the standard form with Heine boilers of both the land and marine-types. The contrast in size between an average water-tube boiler of today and that of 1881 is shown in Fig. 1. To photograph the small National Guard Armory

boiler it was placed on top of a 500-hp. unit which is by no means a large size for present-day practice. Standing alongside of the large boiler is one of the original workmen who helped to build this little boiler, 37 years ago, namely, Joe Garstang, a brother of the proprietor of the shop in which the

placed upon its transport, working hardship upon producers in South America and upon consumers in this country.

The WELLMAN-SEEVER-MORGAN Co. of Cleveland, Ohio, has issued a handsome circular descriptive of its electric hoists. Among the interesting items is an illustrated account of the

FIG. 2. FIRST HEINE BOILER, BUILT 1881, STILL USABLE

work was done. This photograph is of particular interest to the student of the history of steam-plant machinery, as it shows the evolution in the design of each part of the boiler.

### HOW DO YOU FIGURE?

Do you divide the years of service into the cost of paint, plus the cost of labor? If so, you have the correct method of figuring the yearly cost of paint-protection. If you have metal surfaces or any exposed surfaces, whether of metal or wood, to re-paint, it will be worth your while to purchase Dixon's Silica-Graphite paint because the longer service and better quality of Dixon's paint are worth a great deal more than a few cents per gallon. The careful and cautious user of paint will appreciate this fact. For over 50 years the slogan and standard of the Dixon company in the matter of paint has been 'the best and one grade only.' If any one is looking for a low-priced paint and does not care about quality and long service, the Dixon company has nothing for him; but if he desires quality and long service, Dixon's Silica-Graphite paint is the best. Detailed information will be given at any time, with price and assistance in any way. The Joseph Dixon Crucible Co. issues a circular called 'Graphite' for long-service records.

### INDUSTRIAL NOTES

The DEISTER MACHINE Co. is about to issue a pamphlet on its new 'Plat-O' table.

'Thomas Electric Mine-Hoists' is the title of a new bulletin, No. 11, published by the THOMAS ELEVATOR Co. of Chicago.

The 'Revista Semanal,' for November 3, issued by MARK R. LAMB at 30 Church street, New York, contains an interesting article on the question of tin shipments from Bolivia. Owing to the shortage of bottoms severe restrictions are

1850-hp. hoist installed at the Granite Mountain shaft of the North Butte Mining Co., at Butte, Montana.

The KOERING CYANIDING PROCESS Co. has moved its offices, laboratory, and construction plant from Detroit to Salt Lake City. The new address is at 220-224 Dooley Block in the latter city.

ZELNICKER'S Bulletin No. 228, issued early in November, calls special attention to oil-storage tanks. Over 50 of these tanks are ready for shipment, with capacities ranging from 14,500 to 38,500 barrels.

The subscription to the Second Liberty Loan, by the employees of the principal plants of the LINK-BELT Co. and by the company itself, amounted to \$269,000, divided as follows: Indianapolis plants \$104,300, Philadelphia plant \$71,300, Chicago plant \$61,100, and the Link-Belt Co. \$32,300.

FRANCIS S. PEABODY, a well-known coal operator of Illinois, and chairman of the Committee on Coal Production of the Council of National Defense, has been appointed head of the commission that will control the manufacture, storage, sale, and use of explosives under the recent Act of Congress governing these matters.

The GENERAL ELECTRIC Co. in bulletin No. 41021 describes the R. F. line of adjustable speed-motors that are the result of many years of experience and numerous tests under actual operation. Many special advantages are achieved in this R. F. type motor. Two of these that are worthy of mention are the practical elimination of commutation-troubles arising from abuse or careless operation, and the fact that the main field-coils are so designed as to withstand, without injury, full potential continuously with the armature at rest. Special attention has been given to the efficiency regulation, stability, and insulation. An interesting alphabetical arrangement of the various parts of the R. F. motor, together with illustrations and dimensions, will be found on pages 6 and 7 of this bulletin.

### EDITORIAL

NOTES .....	777
AMERICAN SMELTING V. BUNKER HILL.....	779

Review of causes leading to injunction suit against the Bunker Hill & Sullivan; question of validity of assignment of a smelter contract; alleged change of conditions due to monopoly created by plaintiff. *M. & S. P., December 1, 1917.*

MINERAL ON AGRICULTURAL LAND.....	780
-----------------------------------	-----

Proposal to open minerals on agricultural land to location; right of State to minerals under patented land; might be applied to future patents to land in the public domain; retroactive legislation impossible. *M. & S. P., December 1, 1917.*

### DISCUSSION

MILL-TESTS V. HAND-SAMPLING	
By L. A. PARSONS .....	781

Consideration of importance of the Webber combination method of sampling; his 'class 5' not an exception; the mill-check valuable where economically feasible; a difficult case. *M. & S. P., December 1, 1917.*

PROSPECTING CONDITIONS IN CALIFORNIA	
By LEONARD G. BLAKEMORE.....	782

Proposal to reserve mineral rights from agricultural patents and to issue prospectors' licenses permitting location of mineral wherever found. *M. & S. P., December 1, 1917.*

DO WE NEED GOLD?	
By LESTER S. GRANT.....	783

Suggestion to restrict or suspend gold mining in favor of the needs of base-metal mines for labor and supplies. *M. & S. P., December 1, 1917.*

MISSED HOLES IN A WET SHAFT	
By J. F. HARRINGTON.....	783

Request for a remedy or an explanation. *M. & S. P., December 1, 1917.*

## ARTICLES

MIAMI: THE SMELTING OF THE ORE—VI	
By T. A. RICKARD.....	784

Detailed description, copiously illustrated, of the International smelter, which treats the concentrates produced in the mills of the Inspiration, Miami, and Old Dominion copper-mining companies at Miami and Globe. The difficulties presented to the smelter by flotation concentrate and the methods by which they have been overcome in this plant. *M. & S. P., December 1, 1917.*

AMERICAN SMELTING V. BUNKER HILL	
ABSTRACT OF AFFIDAVIT OF E. L. NEWHOUSE.....	797

Career of Mr. Newhouse; development of modern methods of smelting; the balance of fluxes and metals and dependence of smelting-costs on such balance; Bunker Hill interest in Tacoma smelter; reduplication-value of Tacoma smelter; contract between A. S. & R. and B. H. & S. *M. & S. P., December 1, 1917.*

WASTING ORE-VALUES .....	802
--------------------------	-----

Resume of losses incurred in the treatment of Bunker Hill & Sullivan ores. *M. & S. P., December 1, 1917.*

DETERIORATION OF COAL IN STORAGE.....	802
---------------------------------------	-----

Consideration of problems in coal-storage, with special reference to Bulletin 136, U. S. Bureau of Mines. *M. & S. P., December 1, 1917.*

San Francisco

H. G. PEAKE

W. W. JOHNSON

Engineers and Dredge Builders

Agents for Bucyrus Placer Dredges on the Pacific Coast, in British Columbia and Alaska

**F**OR the convenience of prospectors and other locators of mining claims we print the legal form to be used by those desiring to claim the benefit of the Act of Congress suspending the requirement of annual assessment work for the year 1917. It will be found on page 17 of our advertising department.

**I**T is announced that the 200 employees of the Mason Valley Mines Company, at Thompson, Nevada, have agreed to subscribe one day's pay per month to a fund that is to be used "to promote the welfare of American and Allied soldiers at home and abroad." This is a good move. In Canada every man on the payroll of the mining companies gives one day's wage each month to the Canadian Patriotic Fund, which is used in caring for returning soldiers and for the dependents of those at the front.

**U**NDER 'Discussion' we publish another interesting letter on mine-sampling by Mr. L. A. Parsons. The importance of elaborating a reliable method of sampling large bodies of low-grade ore, particularly in gold mines, is emphasized by the collapse of the share-value of the Alaska Gold Mines, which enterprise has suffered from a frankly acknowledged error in ore-valuation due to an incorrect basis of sampling. The shares that were quoted at 40 $\frac{3}{4}$  in April 1915 are now standing at 2 $\frac{1}{4}$ . Even the bonds have depreciated 42%. Thus an original capital investment of \$10,500,000 is imperiled. Obviously it is worth while to ascertain the most reliable way of sampling such masses of low-grade ore as those near Juneau.

**W**E publish a detailed description of the International smelter, at Miami, in this issue. This metallurgical plant is particularly interesting because it is the one smelter devoted entirely to the treatment of concentrate, chiefly flotation concentrate, a mill-product presenting peculiar features. The tonnage treated daily is classified as follows: the Miami supplies 211 tons, of which 93 tons is flotation concentrate and 118 tons is table concentrate; the Inspiration supplies 668 tons, of which 500 tons is flotation concentrate and 168 tons is table concentrate; the Old Dominion supplies 282 tons, of which 52 tons is flotation concentrate and 230 tons is concentrate from tables and jigs. Thus the flotation concentrates constitute 55.55% of the total ore-supply. Un-

doubtedly the coarser products from jigs and tables help the smelter superintendent in overcoming some of the difficulties inherent in handling the slime-product of the flotation-cells.

**O**N page 36 of our advertising department we print a form of application for enlistment in the 27th Engineers, which is the regiment being formed for special mining service in France, as announced in our issue of November 10. We have received requests for these forms of application and we feel sure that this way of circulating them will prove useful. Several companies of the regiment are already in training at Camp Meade, Maryland. The officers will be mining engineers that have undergone preparation in the officers' training camps. The colonel will be a Regular Army engineer officer. The enlisted men will be the men from the mines, more particularly drillers, mechanics, and handy men of all kinds. Again we commend this service to our friends of the pick and gad.

**T**HE weekly review of the metal market as viewed by our correspondent at New York shows that speculation in copper was killed, as was intended, when the Government fixed the price of this metal at 23 $\frac{1}{2}$  cents per pound. In a recent review it was stated that "the relation of consumption to production is a matter of speculation." Some light is thrown on the subject by the latest quarterly reports of the so-called 'porphyry' copper companies. These show that whereas the production of the Utah, Nevada, Chino, and Ray companies was maintained steadily, the sale of copper was withheld after September 21, the date on which the Government fixed the price at 23 $\frac{1}{2}$ . The stocks of copper at the end of the third quarter of the year are valued at 13 $\frac{1}{2}$  cents as compared with the estimate of 28 cents on which profits were based for the second quarter. Why the arbitrary fixation at 13 $\frac{1}{2}$  cents? Is that a possible estimate of cost? The average cost incurred by the four companies during the third quarter of 1917 is given as 11.68 cents per ton; this compares with an average of 7.57 in 1915; but costs are figured in a less camouflaging way in these serious days! Undoubtedly the placing of the Government's hand on the copper market had the effect of causing many of the large producers to hold back their metal with the idea of decreasing the available

supply. It is suggested, by interested parties, that the expansive output required for our warfare will not be obtained unless the producing companies are encouraged, by a rise in the official price, to exploit lower-grade ores. We want to see the copper-mining industry maintained on a profitable and prosperous basis, of course, but we are frank to say that we view with suspicion the placing of the Government's buying in the hands of such organizations as the United Metals Selling Company and the American Smelting & Refining Company, both of which are so heavily interested in the production and sale of the metal. The public is entitled to have the statistical facts as ascertained by official inquiry. It would do much to clarify the position if the Government would make a frank statement concerning the production and consumption of copper in the country as ascertained in the course of the investigation that preceded the fixation of price last September.

ACCORDING to statements made by congressman Julius Kahn, a new draft-bill will be introduced on the re-assembly of Congress in December. He suggests that the age-limit may be extended to 35 or 40 years, and also that young men from 18 to 21 may be called for training. This would appear wise. It is certain that most men reach the fulness of strength and endurance between the ages of 30 and 40. Moreover they develop a maturity of judgment that would make them more efficient and resourceful as soldiers. The younger men would benefit by military training and constitute a reserve-line that would increase the military strength of the nation. At the same time, we believe that consideration should be given to the growing need of a large body of technicians, and that any future bill should provide exemption for all students enrolled in technical colleges and universities until they may have completed their course of instruction. Unless attention be directed to this matter we shall presently experience a shortage of capable engineers, chemists, and physicians that will seriously cripple the country not only industrially but in its preparations for effective conduct of the War.

SILVER has been steady in price lately, after a rise and a fall that must have excited many of our readers. Letters from them indicate a not unnatural anxiety over the market position. One correspondent was perturbed by our suggestion that the Government might use its stock of silver to regulate the price. Another correspondent raised vigorous objection to the Government's purchases of Mexican pesos for re-coinage. The recent narrow range of quotations gives color to the statement, made at Washington, that the governments of the United States and Great Britain have entered into an agreement whereby the entire American output, including that of Canada, is to be purchased on joint account for the purpose of establishing a 'corner' and regulating the price at a figure somewhere between 80 and 85 cents per ounce. A later dispatch from London says that a

portion of the silver to be acquired, as above stated, is to be placed at the disposal of the Indian government, in order to pay for Indian products required in the United States. There is nothing in all this to intimidate the miner; on the contrary, the fixing of the price of silver at any such figure as 80 to 85 cents is greatly to his benefit, and much better than a hysterical market, fluctuating wildly, and affording no basis for steady operations in mine and mill.

DO we need gold—more gold? That is the question submitted by Mr. Lester S. Grant in our discussion department this week. It is a question that deserves an answer. If our gold reserve is adequate, if indeed, as some are claiming, it is excessive, and is responsible for a lessened purchasing-power of the dollar and therefore accentuating the pinch of high prices, then a war-measure discriminating against freight and labor for gold mines might be a justified application of the utilitarian doctrine of doing the greatest good to the greatest number. On the other hand, if our mountainous obligations, incurred by virtue of the stress of war, should at any moment of military anxiety become the weapon of unprincipled men to scare the timid multitude into seeking any available amount of cash for their Government bonds, a calamity might be precipitated unless there were a gold reserve of sufficient dimensions to admit of emergency legislation to utilize it in refunding under some plan of redeemable certificates. Our feeling is one of satisfaction when contemplating that great and growing reserve of bullion in our national Treasury, but we are ready to stand corrected by specialists in finance.

REFERENCES have been made, in the course of the Minerals Separation controversy, to the Canadian patent law. We have obtained a copy of the Canadian Patent Act of 1906 and find that, under Section 38, it requires "the construction or manufacture of the invention patented" in Canada within two years after the grant of patent; and there is the further condition that the invention cannot be imported "after the expiration of twelve months from the grant of a patent or an authorized extension of such period," except under special license. We note that, under Section 44, any person may apply to the Commissioner of Patents for a license to make, use, or sell the patented invention, in the event of the patentee refusing "to grant licenses to others on reasonable terms." It is also provided that the existence of one or more licenses shall not be a bar to an order by the Commissioner for, or to the granting of, a license on any application." If the patentee "refuses or neglects to comply with such order within three calendar months" then "the patent and all rights and privileges thereby granted shall cease and determine, and the patent shall be null and void." Apparently therefore the Canadian law is such that Minerals Separation will find it advisable to behave circumspectly. It is a pity that our own patent law does not provide for similar disciplinary action.

## American Smelting v. Bunker Hill

In our issue of September 8 we recorded the fact that the American Smelting & Refining Company had brought suit against the Bunker Hill & Sullivan Mining & Concentrating Company for infraction of a contract that specified the disposal of the Bunker Hill ore and mill-products. This suit was started in August and was meant to prevent the Bunker Hill company from smelting its own ore in its own smelter, which has been built near the mine at Kellogg, Idaho, and had begun operations in July. A petition was presented by the American Smelting company to the U. S. District Court at Portland, Oregon, asking for a temporary injunction against the continued operation of its smelter by the Bunker Hill company pending the trial of the suit. This petition came up for hearing before Judge Wolverton at Portland on November 7. A decision may be expected shortly.

The bill of complaint alleges that on March 20, 1905, a contract was signed between the Bunker Hill company and the Tacoma Smelting company; and that by this contract the Bunker Hill agreed for 25 years to ship all its ore that contained between 30 and 75% lead to the smelter at Tacoma; all the products of the mine and mill that assayed outside these specified limits being open to purchase by the Tacoma smelter on payment of the best going rates and terms. The contract provided also that the products specified should be subject to competitive rates after the first five years. On the day following that on which this contract was ratified, the American Smelters Securities Company, a Guggenheim organization, acquired all the stock of the Tacoma Smelting company, which in June 1917, but not until then, assigned the contract itself to the American Smelting & Refining Company. Our readers will remember that in March 1905 the American Smelters Securities Company, through Mr. Bernard M. Baruch, bought not only the Tacoma smelter but also the Selby plant, near San Francisco, and thereby the Guggenheims prepared the way for their control of the lead-smelting industry. Two years earlier the American Smelting & Refining Company had bought the Everett smelter, in Washington, and in 1905 this property also was transferred to the Smelters Securities Company. In 1912 the Tacoma plant was converted into a copper smelter and ceased to treat lead ores. As we understand the point at issue between the litigants, the Tacoma smelter was entitled to, and bound to take, all the Bunker Hill ore, concentrate, and slime assaying between 30 and 75% lead, but the smelter had the option of purchasing the outside products only "at best going market rates and terms." The idea that the Tacoma smelter was entitled to all the products of the Bunker Hill mine is asserted by the defendants to be directly contrary to the express letter of the agreement. It is also claimed by the defendant that the option on these outside products lapsed with the rest of the contract when the latter was assigned to the Smelters Securities company, in which the American Smelting com-

pany owned only 17 million dollars worth of stock, out of the total of 77 millions. It is obvious, however, that the ore-contract was intended for the benefit of the smelter trust, which acquired the control of the Tacoma smelter on the day after the contract was signed. The Guggenheims bought the control of the smelter from the principals of the Bunker Hill company. In effect, the plaintiff company asserts that it was the real purchaser of the defendant's controlling interest in the Tacoma smelter; that the purchase was made with the idea of securing all the ore produced by the Bunker Hill for a period of 25 years, so that the Bunker Hill people would not go into the smelting business again for that length of time, and that the main reason for the new Bunker Hill smelting enterprise is the cupidity aroused by the abnormal price of lead due to the War. To this the defendant company replies that the plaintiff was not the real purchaser of the Tacoma smelter; that all the Bunker Hill product was not covered by the 25-year contract; that the Bunker Hill people incurred no obligation to abstain from smelting operations; that cupidity played no part in the decision to build the smelter at Kellogg, this step having been taken before the War raised the price of lead; and that one of the reasons for building the smelter was the fact that the Guggenheim combination had so suppressed competition in ore-buying that the Bunker Hill company could find no market for such of its products as were not covered by the 25-year contract, namely, ore and mill-products assaying outside the limits of 30 and 75% lead. It is also charged that the Guggenheims during the first five years of the Tacoma contract killed the benefit of competitive terms on the medium-grade products specified in the contract. The other legal defences of the Bunker Hill company may be summarized as follows: The 25-year smelting contract was made between the Bunker Hill company and the Tacoma company; for seven years the latter received part of the Bunker Hill ore at its Tacoma plant and delivered the remainder to the plants of the American Smelting company. In 1912 the Tacoma company ceased to operate its lead plant and since that time all the Bunker Hill ore has been diverted to the plants of the American Smelting company. There has been no contract between this company and the Bunker Hill, but in June 1917, after the Bunker Hill smelter had been completed, the American Smelting company procured an assignment of the Bunker Hill's Tacoma contract and is now seeking to enforce that contract in its own name. The Tacoma company, with which the contract was made, has no plant in which it can treat the Bunker Hill ore and therefore is not damaged if such ore is smelted at Kellogg. The Bunker Hill company contends that the contract could not be assigned without its consent, because the contract imposed financial obligations on the Tacoma company and the Bunker Hill company has a right to say that it will not look to any other company for a performance of those obligations. The U. S. Supreme Court has held that a smelting contract such as this cannot be transferred by one company to another.

In any event, it is a fact that the contract was amended in 1907, two years after it was signed, so that the Tacoma company agreed during the life of the contract to pay for the lead in the Bunker Hill ore at a price made by the American Smelting company in New York City on the day of shipment. In other words, the Tacoma company and the Bunker Hill company agreed to let a third party fix the price for the lead each day, and settlements were made accordingly. Now the arbiter, or price-fixer, claims to have taken an assignment of the contract and seeks the aid of the Court to compel the Bunker Hill company to deliver lead ore to him—the plaintiff—the American Smelting & Refining Company—during the next 12 years at the price to be fixed by him or it. That is asserted by the defendant to be indefensible. Undoubtedly the sore spot in the controversy is the killing of competition—of the competition for which provision was made in the contract of 1905—and the establishment of a ‘cinch,’ or monopolistic control, by the smelter trust not only over the Bunker Hill output but over that of the whole Coeur d’Alene region.

On another page we publish the affidavit made by Mr. Edgar L. Newhouse in support of the complaint lodged by the Guggenheim company. We have omitted some of the elementary technology, such as is needed apparently to instruct the Court but would be tiresome to our readers. We have also ventured to correct the affiant’s relative pronouns, substituting ‘that’ for ‘which’ in such sentences as seemed to require the change. In our next issue we shall publish the larger part of Mr. F. W. Bradley’s affidavit, and subsequently we hope to give our readers the counter-affidavits of the two leaders in the controversy, believing that these statements made by distinguished members of the profession will prove of particular interest at this time.

## Mineral on Agricultural Land

Many prospectors will sympathize with the position taken by Mr. Leonard G. Blakemore in his discussion of the interference of agricultural titles with the development of mineral resources, printed elsewhere in this issue. He maintains that the discoverer of a mineral deposit should be entitled to locate and to hold it for active development against any owner of surface rights, subject, of course, to adequate recompense for appraisable damage done to the interests of the aforesaid owner; he would also have the United States copy the Australian system of granting prospectors’ licenses, carrying with them the right of entry upon the estates of agricultural owners, and of valid location when mineral is found. With all this we confess to cordial sympathy in principle, and we are pleased to endorse Mr. Blakemore’s suggestion that engineers respond with discussion of the problem. It is a broad and important question, and should command serious attention. The West still holds a large area of public land, and it might be well to assert the ancient principle of the inalienability of minerals from the sovereign state so far as relates to lands that may be

patented in future. Retroactive laws are contrary to the spirit and practice of our democratic institutions, and are, moreover, contrary to our fundamental law. Therefore some other remedy must be sought for the unlocking of the buried treasure on lands patented in good faith in accord with previous Acts of Congress. Ingenious methods of taxation sometimes prove a key that will unlock such difficulties. To undertake the unsettling of rights secured by title, however, would be to trifle with the stability of those sacred principles of possession that our Constitution is supposed to guarantee. If a patent once granted under the great seal of the United States can be thus lightly scorned, there would be nothing that a majority in power might not take away; it would be to invite anarchy under the guise of democratic form and procedure. We have already said that we believe in the essential justice of Mr. Blakemore’s argument, but the correct basis of political evolution is growth by variation, not change by radical excision. It depends on the antecedents of present law as to what may be permissible. The custom of the world was once that the metals belonged to the king; that was a universal reservation, but that principle was not affirmed in the United States with reference to the public lands. The Government, in fact, undertook to discriminate between agricultural and mineral land, and to classify them accordingly. It was an almost impossible task, and has worked much hardship. What Mr. Blakemore had in mind, when he affirmed that the United States owns the minerals in lands to which agricultural patents have been issued, is probably the fact that in many of the Eastern States, where the laws of property were derived from Colonial charters, the ancient sovereign prerogative is asserted; the present statutes, in other words, are drawn in the light of their origin. In the State of New York a discoverer of mineral is protected in a half-interest to the deposit found and also in its control for exploitation; he may file his claim with the Secretary of State, and forfeiture is possible only through failure to develop and work the mine continuously. This we believe applies to gold, silver, copper, zinc, and lead. In North Carolina the fee-holder has the prior right to the mineral under the land, and may convey it separately from the surface right; but it does not automatically follow the title on conveyance. Unless specifically assigned the mineral-right reverts to the State and may be claimed by a subsequent discoverer. Likewise in Spain, which may be cited appropriately as the oldest and greatest mining region of Europe, the sovereign right exists unimpaired, and a discoverer may obtain a leasehold under which to develop and operate. The same is true in Mexico and in all the Spanish countries, where sometimes mining claims are located in populous cities. It is an old principle and a sound one; nevertheless retroactive laws may not be considered in free America, the country that has ever insisted on individualistic right. Without cause founded on delinquency we may not take from a man that which the law has given him.

## Mill-Tests v. Hand-Sampling

The Editor:

Sir—I have followed with interest in your columns the discussion on sampling large low-grade orebodies, a discussion which has lately been somewhat narrowed to a comparison of the relative merits and peculiarities of mill-tests and hand-sampling. This narrowing is a good sign; it points, as does the text of the succession of articles and letters, to something approaching agreement among your various correspondents as to the basic principles of good practice. The discussion has thus performed a most useful service in clearing some of the fog; but by showing how much your various skilful contributors agree in fundamentals it has served to accentuate the differences in details. It is about some of these details that I am writing to you today. A close agreement on these will probably never be reached, as the details of good practice are as varied as the orebodies that call them forth; but a further discussion of them may lead to a better understanding of the possible consequences resulting from their variation.

In your issue of September 29, Morton Webber describes a method of using the mill-test for determining the factor of error in hand-sampling. I am glad to see from a previous article of Mr. Webber's that he places his main reliance on hand-sampling, and uses the mill-test only as an aid in interpreting his results. Thus far we are in agreement. His 'Class 5,' a type of orebody for which, in a previous article, he makes an exception to this general rule, is a type extremely difficult to sample correctly, and, in the unusual cases he has cited, great accuracy is impossible by any economic method. Nevertheless, I believe this class does not constitute a true exception, and that the independent engineer will be better able to estimate the possibilities of such an orebody, as of a more uniform one, if he bases his opinion on hand-work alone rather than on mill-tests alone. This, however, is a digression. As a general principle, the checking of hand-samples by mill-tests, if carefully done according to some such method as that outlined by Mr. Webber, gives information that cannot fail to be valuable. I would hesitate, however, to support the argument that an exact sampling-factor can be thus determined; rather the information obtained will be valuable in a general and not too precise way, as an aid in estimating the reliance to be placed on the hand-sampling, and the variations and trend of the sampling-factor. I am ignoring the function of determining the most advantageous metallurgical process; for that pur-

pose a mill-test, or at least a test on that scale, is practically always necessary. I am confining myself to the best means of determining the tenor of the orebody, pure and simple.

For the combination method as outlined by Mr. Webber, it is not necessary that the mill-test be representative of the entire zone from which it is taken. The best that can be expected is that it will be representative—or rather, show the entire mineral content—of the tonnage actually milled. This fact is clearly stated by Mr. Webber. The tenor obtained for the small tonnage milled is, to all intents and purposes, exact. In order to obtain an accurate sampling factor it would be necessary for the channel-samples, cut from "successive . . . . . stope faces as the ore is removed for a mill-test," to be as representative of the small tonnage of ore milled as the mill-test itself. But this cannot be so. Please note I say 'representative,' not 'accurate.' Singly or in small groups, hand-samples are not supposed to be representative. It is only in large numbers that their individual variations merge in an average that is reliable. This basic fact, a clear understanding of which underlies all successful hand-sampling, is frequently overlooked. The average of all the samples taken on an orebody may thus be close enough to its actual tenor for the business in hand, and yet small groups of these samples, segregated according to zones, may not be truly representative of the parts of the orebody from which they are taken. This fact becomes more noticeable as the orebody becomes more erratic, a truth recognized by Mr. Webber when he states that "the principles of this 'combination method' will apply to best advantage in mines of fairly uniform mineral characteristics."

To refer to Mr. Webber's Fig. 2, if it is assumed that the area *A, B, C, D* indicates the whole of the orebody, then if the orebody is moderately erratic—the sampling of which difficult type we are discussing—it could hardly be expected that the samples within the area *A, E, K, O* would be representative of the tonnage indicated by this area. Still less would the samples from the little triangle represent the, compared to the whole deposit, minute tonnage milled. The sampling-factor obtained would then be partly due to the inherent sampling-factor, and partly to the fact that the comparatively few hand-samples would fluctuate widely according to purely accidental variations. The factor thus obtained might or might not hold good for the rest of the zone. The whole thing comes down to the fact that hand-sampling depends for its accuracy upon the averaging of a *large number* of (sometimes) widely divergent results. It is

the safety created by this large number of samples more than any other factor, more than the tonnage represented by each sample, more than the tonnage per foot of development, on which the hand-sampler depends, and which makes his results reliable. To grade a deposit carefully on samples in sufficient numbers to be reliable, and then to alter this grade according to results obtained from a small proportion of these samples, is to introduce the weak link of the chain, to throw overboard much of the safety so arduously acquired.

One more point. To my mind, a large part of the sampling-factor so consistently obtained at various mines is due to an erroneous estimate of the waste that will be unavoidably broken with the ore. Waste from hanging, waste from foot, waste from included 'horses'—it is so easy to under-estimate these, to assume that the 'hanging' and 'foot' will stand well, that the horses can be left as pillars, or at least broken separately from the ore. Sometimes I think it is almost impossible to be sufficiently liberal in this respect. And on this element Mr. Webber's method would throw no light. In the absence of tests practically on an operating scale, the engineer must still estimate the amount of dilution according to his unaided judgment.

All of which leads me to state that I believe Mr. Webber's method will be valuable in a deposit where it is economically feasible, provided it is used by a highly experienced man purely as an aid to the broad interpretation of his sampling; but that on account of the relatively few hand-samples compared with each mill-test, and the inability of such small tests to give results which include dilution with waste, its use to determine mathematically a sampling-factor might be extremely dangerous. For many of the most knotty problems, the very problems where the sampler is most sadly in need of help, its use would be impossible owing to the utter lack of agreement between the sampling-factors obtained. I remember one deposit for which a half dozen sampling-factors, each obtained by comparing between 1500 and 2000 hand-samples with 30,000 tons milled, were hopelessly contradictory. On more uniform deposits an apparent agreement might mask an error greater than that in the hand-samples alone. Although I should be glad to have such information for any deposit I had examined, I am not sure in what manner I should use it; such a weapon is two-edged. I shiver to think of the results that might follow its hasty application to any but the most uniform deposit, and it is methods of sampling the erratic perverse deposit with which this discussion is largely dealing.

L. A. PARSONS.

New York, November 1.

[We are glad to publish this further thoughtful contribution from Mr. Parsons to the discussion, and we hope that other engineers, experienced in the sampling of large low-grade gold mines, will contribute. It seems to us that Mr. Webber's suggestion, apart from its immediately practical value, should continue to serve as a subject for useful discussion.—EDITOR.]

## Prospecting Conditions in California

The Editor: •

Sir—The prospector is the pathfinder and pioneer in many countries. Some cynical person will exclaim, "Yes, but he is so for his own benefit in the discovery of minerals, mainly gold." That leads to another question, what made this great State of California, if not gold and the prospector of '49 who discovered it? Therefore I contend he is the maker of trails, the pioneer of the vast areas now populated with teeming thousands, and reaping the benefits of his hardihood and privation. Gold still abounds in California, but under what conditions does the prospector now start on his trip? He sallies forth, as in the past, and devotes days and months to the search for something worth while, and if he does find a vein, or a gold channel, he is fortunate if he is not chased off by a bull-dog, or by some individual holding the ground under a patent as agricultural land, even though a jack-rabbit might be lucky to get a living on it. Under these agricultural patents thousands of acres are held in California that are purely mineral lands and fit for nothing else. Under the laws of the United States all mineral belongs to the Government. If the prospector decides to talk the matter over with the owner he is held up for a prohibitive sum to acquire something the patentee should have no right to sell if the mineral laws were so adjusted as to give the prospector the primal right of discovery. Upon the discovery of mineral land held under an agricultural patent the surface rights and such ground as needed for mining purposes should be purchasable at a fair price, or secured through a court of arbitration, appointed for that purpose. There are hundreds of prospectors in the State who know of promising mineral deposits, but are barred from locating them because the owner of the agricultural patents will not allow prospecting done on their lands. Thus Uncle Sam's mineral deposits lie idle and undeveloped, when they could be made a source of revenue to the country! In Australia they had the same evil but eradicated it through laws that made minerals the property of the State and by issuing leases only for 21 years, which are renewable at the option of the lessee, but here an owner of patented land can lock it up for a lifetime simply by paying small taxes upon it. In Australia, if one person desires to farm the surface he pays a farming license; if another desires to mine in the same ground he pays a miner's license, so the Government may receive two revenues from the same piece of land. The lessee, moreover, must keep a man nine months in the year upon the property and mine and develop it. A miner who locates a claim has to work eight hours a day upon his claim. If he runs out of provisions or money he can acquire a leave of absence from the district commissioner for one, two, or three months. He then posts his notice to that effect beside his discovery monument to prevent 'jumping' the claim. The land can be exploited and need not lie idle as in California today. A miner's license in British Columbia costs \$5 per year and

enables the prospector to locate not more than one claim on any creek or hill and not more than two in the same district. He may, by purchase, however, hold any number of claims; but he cannot prospect or mine without such a license. There should be a thousand men in the hills of California searching for mineral where there is one today. The production of gold is decreasing in California. The placers are gone, but the 'leads, veins, and lodes' remain mostly untouched, because they are on patented agricultural land. This is true of most of the great Mother Lode. When a person applies for an agricultural patent he has to swear that no mineral exists, to the best of his knowledge, upon said land. If the patentee discovers that mineral exists upon this land he immediately tries to dispose of what he swore did not exist. The poor prospector that stumbles upon mineral and tries to acquire a right to it after doing a lot of work upon it is stopped when it is discovered that he is on patented land. The owner then wants \$20,000 down, \$10,000 more in 30 days, and so forth. That is the average result, and the prospector heaves his 'chew' into a distant spot and departs in disgust. With a miner's license in his pocket, if such existed here, he would be able to locate the mineral deposit and exploit it, paying a reasonable sum per acre for any surface rights required for mining purposes. These things should be made the subject of agitation wherever and whenever the A. I. M. E. meets; they should be brought to the attention of congressmen by engineers and miners; they should be brought to the attention of senators in Washington, until a reform is made, and land that is now bringing in practically nothing to Uncle Sam would be made to yield revenue in the near future, for the benefit of the whole State, directly or indirectly, though giving employment to miners, in the distribution of dividends, and in the payment of taxes.

LEONARD G. BLAKEMORE.

Mokelumne Hill, California, October 31.

## Do We Need Gold?

The Editor:

Sir—Why is Gold Mining? Is not the question a pregnant topic?

I have read your editorial on 'Foods, Metals, and Labor,' in the issue of the 10th inst., and also the circular of the National City Bank, to which you refer. From perusal of their monthly circulars, and other sources, it is my understanding that our present reserve of gold is ample for the needs of the War. If such is the case, should we, in view of the national emergency, be allowed to continue mining gold? It is my belief that this question is in the minds of many, particularly those following the branch of the mining industry in question. Would not the airing of current views on the subject, through the columns of your valued periodical, be of sufficient worth to warrant the space?

The reasons against the present mining of gold are

obvious. The industry employs labor, consumes metals, explosives, fuels or power, and foods in the production of a metal not directly employed in actual warfare. All of such consumption would, of necessity, find its way into other channels. It is equally obvious that to suddenly stop gold mining, even temporarily, would work great hardship, not to say ruin, on thousands of individuals, especially in camps like Cripple Creek, where the mining of gold is the sole reason for the existence of the community. But War does that very thing. If the national need of gold is less than the national need of what the industry consumes, then the industry should cease.

As one who, ever since becoming self-supporting, has followed gold mining as a means of livelihood, I would appreciate greatly having the views of those who, like yourself, have a much wider view than I am permitted. And I would especially call your attention to the fact that if such 'regulation' is even remotely in the minds of our government officials, then the quicker that it is brought to the attention of the industry, the better may we prepare ourselves for the blow.

LESTER S. GRANT.

Stent, California, November 16.

## Missed Holes in a Wet Shaft

The Editor:

Sir—Can you tell me the cause of missed holes in a wet shaft? The primers are made with the regulation fuse and standard blasting caps. The cap and fuse are then painted with P & B paint after being crimped with what the foreman says is the best crimper made. Still we have missed holes even when two primers are used in a hole. I noticed the primers hanging up in the shaft-house with the caps down, and I thought that perhaps the paint itself got into the cap before the fuse was sent down the shaft, or perhaps that the paint penetrates the fuse. The fuses are made whenever the hoist-man finds the time. We are having missed holes so regularly that it is getting on my nerves.

J. F. HARRINGTON.

Chloride, Arizona, November 22.

[The causes of misfires are so many that it would be mere chance to hit upon the difficulty experienced in any particular case. A critical investigation of every detail will usually reveal the trouble. An article on this subject will appear in our next issue, when a reply will be made to this query.—EDITOR.]

THE BUREAU OF MINES has been working on a method for utilizing the waste sulphur gas at smelters. The SO<sub>2</sub> is the most abundant constituent, and this is an excellent solvent for oxides of copper and zinc. Among the problems involved in the use of this gas as a lixiviant is that of obtaining it from the smelter in a sufficiently concentrated form, and also the precipitation of the metals from the sulphurous-acid solution.

FIG. 4. CROSS-SECTION OF THE INTERNATIONAL SMELTING CO.'S PLANT

## Miami: The Smelting of the Ore—VI

By T. A. RICKARD

The various concentrates made in the mills of the Inspiration and Miami companies are reduced to blister copper at the neighboring smelter, a plant belonging to the International Smelting Co. The distance from the Inspiration mill is 8000 ft. by rail and from the Miami mill 17,500 ft. This smelter is the first to be designed for the particular purpose of treating flotation concentrate. Of the total charge of ore (1200 tons) treated daily 75% is such material. The Inspiration supplies 668 tons daily; the Miami, 211 tons. Of this, 68% is flotation product and 32% table concentrate. Besides the concentrates from the two mills at Miami, the smelter also receives daily about 50 tons of flotation concentrate and 230 tons of table concentrate from the Old Dominion mill at Globe.

At the time of my visit the International smelter was treating 1500 tons per day, but a new reverberatory furnace was under construction, to increase the capacity by 600 tons more. Of the 1500 tons of charge, 20% is 'secondaries' and flux; 80% is 'ore,' that is, concen-

trate. The 'secondaries' include converter-slag and matte-skulls, some of which go back to the converters. A small tonnage of oxidized ore from the Live Oak workings of the Inspiration goes direct to the converters, where it serves as a silicious flux. The total of oxidized copper ore averages 116 tons per day. The limestone and the oxidized copper ore go to the receiving-bins and thence to the coarse-crushing plant, from which they are conveyed to the storage-bins.

The flotation concentrate arrives in 60-ton hopper-bottomed railroad-cars; it carries 17% water, but a little lime added at the mill is most useful in preventing the moisture from working to the top. For the haulage of this concentrate a special car has been designed. It is tight and easy to unload. A longitudinal opening or slot, 22 inches wide, extends along the bottom, on each side of which is a shelf, so that wooden slats (6 in. wide and 26 in. long) can be stretched across the opening, to close it. These slats overlap, as is shown in Fig. 1, which is borrowed, together with Fig. 2 and 3, from a paper con-

FIG. 10. SECTIONS OF SKULL-BREAKER

FIG. 11. PLAN OF SKULL-BREAKER

tributed by A. G. McGregor to the Institute.\* The slats on the narrow bottom of the car are pushed tightly together by means of a steel plate that is made to slide forward by a screw operated by a hand-wheel at one end of the car. On this steel plate rests a slightly tapering steel plug, at the top of which is a lug *p* by which it can be lifted. Upon arrival at the smelter the plug is lifted by a chain-hoist on a trolley overhead, the plate is moved back by the screw and wheel, an opening 18 in. wide is made, and the concentrate begins to fall out of the car. The concentrate has to be poked with long chisel-pointed bars, worked by men standing on top of the car. When a little of the bottom has been cleared, the slats are shifted sideways successively, allowing the concentrate to fall upon the conveyor running underneath the track.

The concentrate is sampled for moisture by running the galvanized-iron spout of a 'coffee-pot' up the face of concentrate at seven intervals along three vertical faces in each car. This is done while the car is being unloaded. The sampling for assay is done by 1½-inch augers, making 24 bores. This applies to flotation concentrate and to slime-table products. The sand-table concentrate is sampled for moisture as above described, but the sampling for assay is performed automatically by a bucket-chain, which takes two tons out of each 50-ton carload. Mr. McGregor describes the sampling of the concentrates and remarks that the method in use works satisfactorily on table concentrate but not on the flotation product, because the stickiness of this material causes it to form large chunks, which fall on the conveying-belt and give it an uneven load. Since he wrote this the effort to sample the flotation concentrate automatically has been abandoned, but his description of the practice, as applied to the table concentrate, is quoted herewith:

"It will be noted that the conveyor from the unloading-pocket discharges onto a shuttle-conveyor (a tripper on the former conveyor could have been substituted for the shuttle-conveyor, but it would not have handled the sticky concentrate as well). Buckets attached at their ends to chain-belts are arranged to cut through streams of concentrate as it is discharged onto the shuttle-conveyor. The chains are driven and supported by sprocket-wheels. The arrangement is such that at the highest point in their travel the buckets are in an inverted position. At this point they pass under a revolving shaft which has a number of knockers, made of 6-in. belting, attached to it. These knockers slap the bottom of the buckets, jarring loose any concentrate tending to stick to them." See Fig. 6 and 13.

The traveling belt at the bottom of the unloading-pocket is 22 inches wide and delivers the concentrate to any one of three belts passing over the bedding-bins, which are 150 ft. long and have a capacity of 12,000 tons. Each of the three belts has a tripper, operated by motor and movable as desired over the bins. 'Secondaries' and limestone, both in a crushed condition,

enter on another belt, which delivers its burden upon the belts running over the bins just before the concentrate begins to arrive. The slimy concentrate splashes as it is discharged upon the belts and off them, making an even feed impracticable. The bins have V-shaped bottoms closed by 28-in. slats covering a narrow longitudinal opening. Again the descent of the material has to be assisted by shoveling or hoeing; it discharges upon a 20-inch belt delivering to a 22-inch belt that runs to the top of the building in which the drying is done. The concentrate falls into steel bins discharging through apron-feeders. Here likewise the concentrate has to be pushed from the top by the use of long bars. It falls upon the top hearth of the furnace. Of these Wedge furnaces there are six, and four more were under construction at the time of my visit in May.

Each furnace has five hearths, besides the one on top. The interior diameter is 20 ft. 4 in.; the shell is 22 ft. 7 in., and the total height is 17 ft. 10½ in., so that each drying-chamber is 39 inches high. Heat is supplied by three fish-tail burners in each furnace. The lining is 12 in. thick. Each rabble makes one revolution in 55 seconds and the total period of drying is 1½ hours. The ore is turned by four arms, each carrying five 6 by 14-in. rables. The furnace treats 50 tons per hearth in 24 hours. It is air-cooled. After passing through the rabble-arms the air passes up the central shaft to the top, whence it is conducted to the fire-boxes connecting with the two lower hearths. Thus heated air is provided for the combustion of the oil by which the firing is done. The treatment is drying, not desulphurization; the elimination of sulphur is confined to the small particles that are suspended in the air and come in contact with the flame. The decrease of sulphur is not known but it is very slight, from an original percentage of 19.52 in the feed to the dryer. During 1916 the average sulphur was 18.72%. Owing to a change in the charge consequent upon the receipt of Old Dominion concentrate there is a tendency to increase the sulphur content and decrease the copper content, the result being to lower the grade of the matte produced in the reverberatory. An experiment was made with the use of a steel I-beam as a rabble-arm in these Wedge furnaces, instead of the ordinary air-cooled cast-iron arm, but it was not successful, owing to the bending of the arm when hot. This heating was due to the settling of flue-dust, which became incandescent and prevented the rabble from being cooled by the air. Then an A-shaped cover of concrete was built over the rabble, so as to expedite the shedding of the flue-dust. This was an improvement over unprotected arms. The use of I-beam arms, however, is being discarded.

During the first six months of 1917 the product from the dryers averaged as follows:

	%		%
Silica .....	17.73	Iron .....	17.15
Sulphur .....	19.73	Alumina .....	6.42
Copper .....	26.47	Lime .....	3.83

The Cottrell plant for arresting the dust consists of 12 units of 20 tubes each; it is placed immediately above

the drying-furnaces, as shown in Fig. B. The lap-welded steel tubes are of 13 in. outside diameter and 15 ft. long. They are cleaned by knocking every two hours. The dust drops when thick enough, but if allowed to accumulate it may fill the tube to such a thickness as to cause disruptive discharge of electricity across the tube. The dust is extremely fine and is detached by a rap from a series of hammers suspended on a bar, so that the movement of a lever causes them to strike the pipes. A potential charge of 75,000 volts is maintained. The lavish sparking of the rectifiers suggests the intense potential of the electric energy in use. These rectifiers receive an alternating current from the transformers and in turn convert it into a pulsating direct current. The electric current is distributed within the pipes either by No. 1 jack-chain or No. 16 nichrome wire. For those unfamiliar with this useful apparatus, I may explain that the principle of the Cottrell tube is the electrification of suspended particles by the discharge of high potential electricity into the gases and dust escaping from smelting furnaces. The individual particles acquire an electric charge by which they are caused to be attracted by the opposite unlike polarity of the tube. The first step in the operation is discharge of free electricity from the wire or chain into the gases; these charges of electricity are immediately condensed upon the particles of dust, which then become repelled by the wire, which is of the same sign, and attracted by the walls of the metal tube, which are of the opposite sign.

The dried concentrate drops from the Wedge furnaces into hoppers that load 20-ton cars, which are moved by an electric trolley to the reverberatory building. There the dry concentrate is discharged into hoppers, each holding one car-load. See Fig. 7.

The transfer of the powdery concentrate from the drying-plant to the reverberatory building calls for precautions against dusting. This is accomplished by means of a car of special design. My description is borrowed from Mr. McGregor. In the top of the car are four sliding sleeves that are spaced so as to correspond with the discharge-openings of the hoppers at the drying-plant. When the car is in position for loading, the sleeves are forced against the hoppers by means of levers on the side of the car. The lever is made of flat spring-steel so that the sleeve can be pressed into firm contact with the flange at the bottom of the hopper and held in place by the lever becoming fixed by a notch in a quadrant on the side of the car. The spring handle ensures sufficient pressure between the sleeve in the top of the car and the flange on the bottom of the hopper so as to make a tight connection, regardless of the small variations in distance between them or of any lost motion in the play of the lever on the sleeve. A vent of closely woven wire is provided in the car. Fig. 8 shows the corresponding sleeves attached to the top of the hoppers at the reverberatory furnaces. When the car arrives from the drying-plant a lever operated from the charge-floor forces the sleeve against the flange on the discharge-spout of the car. The lever is engaged by a catch while the car is

being emptied. A close contact between the sleeve and the spout is ensured again by a helical spring, so that lost motion, wear of the levers, and variations of distance do not cause leakage. See Fig. 5.

Each of the hoppers feeds a drag-chain conveyor that supplies a reverberatory furnace, of which there are three.† The drag-chain runs within a rectangular sheet-iron conduit (3 ft. high by 1½ ft. wide); this scrapes the dried material forward and feeds it through openings distributed along the side of the furnace at intervals of 30 inches, except at the extreme front, or skimming end. The feed is admitted where desired by withdrawing a slide in any one of a series of spouts leading through a 6-in. pipe into the furnace. Formerly the feed entered along the centre of the back of the furnace, but this involved excessive loss by dusting. The firing itself is done by five 1¼-inch round burners using Californian crude-oil, at the rate of 0.75 bbl. per ton of dry charge. A little silica, for fettling, is introduced at the front of the furnace. At the time of my visit Old Dominion flue-dust was being fed; this is dry and self-fluxing; it is so fine as to be unsuitable for transport on open belts. Each reverberatory receives about 16 tons of the dried product per charge. Besides this, the furnaces handle all flue-dust produced by the plant as well as all the hot converter-slag. Thus composed the charge of 20 tons contains

	%		%
Silica .....	18.0	Iron .....	21.7
Sulphur .....	16.2	Alumina .....	6.1
Copper .....	23.9	Lime .....	2.3

The increase of iron received from the converter gives the slag-forming ingredients, without which the charge would be too infusible to permit the separation of matte. De-sulphurization in the reverberatory is at the rate of 28%.

The slag from the reverberatory contains

	%		%
Silica .....	41.3	Iron .....	32.9
Sulphur .....	0.4	Alumina .....	14.0
Copper .....	0.75	Lime .....	5.4

The slag is skimmed into cars of 225 cu. ft. capacity that take it to the dump. Four cars of slag are usually skimmed at a time. The cars are hauled to and from the dump by a 24-ton electric locomotive and are dumped electrically by means of a motor mounted on each car.

The matte is tapped as it accumulates; it runs along a miniature ditch made of banked silicious ore (without the aid of any metal sheeting) into a steel ladle of 25 tons capacity. This is lifted by a 40-ton Morgan electric crane and poured into a converter lined with magnesite brick. The magnesite brick has deteriorated sadly since the beginning of the War, the consequence being that the brick crumbles easily, owing to lack of uniformity in the bonding substance. The matte averages

	%
Sulphur .....	24.2
Iron .....	23.2
Copper .....	49.7

†Another has been built since my visit.

FIG. 12. PLAN OF THE INTERNATIONAL SMELTER

FIG. 13. SECTION THROUGH UNLOADING POCKET

Silica, in the form of silicious copper ore, is added to the converter as a flux to remove the iron in the matte. This flux is fed into a bin through a measuring-hopper. The charging is regulated from the ground-floor by means of a system of levers. Matte-skulls, scrap-copper, and the general clean-up material are fed into the converters. Of these there are six, with five stands.

The average length of blow is 3 hours 9 minutes. The air used is 112,000 cubic feet per ton of iron and sulphur in the matte. Copper is poured at the end of each blow; the slag is removed as it accumulates, say, two or three times during the blow, depending upon the proportion of old slag and other easily fusible material that may have been added.

The converter-slag contains

	%		%
Silica .....	20.2	Iron .....	44.7
Sulphur .....	2.0	Alumina .....	4.1
Copper .....	4.0		

This goes back to the reverberatory.

The copper from the converter is poured into a ladle and transferred to a tilting brick-lined furnace heated by an oil-burner, using 1.75 gal. per ton of copper. The pouring of the copper from this furnace, or 'kettle,' is effected by an electric motor (as is the tilting of the converters), the periphery of the furnace resting on wheels actuated by the motor. The copper is poured into a clay-

lined spoon and thence into the molds of the straight-line casting-machine, which consists of a series of molds on an endless chain. Four of them are filled and emptied each minute. The molds are made (at the plant) of blister copper with a cast-iron splash-plate, 12 by 12 inches, cast into the bottom. The splash-plate prevents the hot copper from melting the cold copper and so burning a hole through the bottom of the mold. The copper carried by the casting-machine is cooled in its passage by a spray of water and is detached by being pried with a bar in the hands of an attendant. Each slab of copper weighs 250 to 260 lb. Two at a time are taken on a two-wheeled truck to the trimming-floor, where the 'fin' or fringe, is removed previous to weighing. See Fig. E, F, and H.

Thus 333 tons of blister copper, assaying 99.5% is made daily. In the first 15 days of May 5000 tons of copper was produced. In April, owing to the embargo on shipments to Galveston, a stock of copper valued at \$1,250,000 was accumulated. The copper goes by train to El Paso, thence to Galveston, there to be loaded on vessels of the Morgan line, which take it to New York, on the way to the refinery at Perth Amboy.

The breaking of 'skulls,' or hard crusts of matte and slag, is done by dumping them upon a heavy cast-steel grill, the base of which supports the frame of a pile-driver. This consists of a hammer that descends between guides; it is mounted on a trolley and actuated by a motor-driven hoist, the whole mechanism being placed on a traveling bridge so that the hammer can be dropped on any part of the grill or grating, as shown in Fig. 10.

The smelter employs 350 men on average, the number of names on the payroll ranging between 348 and 515. The lowest pay is \$2, to which is added the bonus based on the price of copper. In May the bonus was \$1.65, and in April \$2, so that the men received \$3.65 and \$4 in these respective months.

For most of my information and for other personal courtesies I am under pleasant obligations to Lawrence Ogilvie Howard (McGill '00), the superintendent of the plant. I give his name in full because there are three other professional men with the same initials, besides the Secretary of the American Association for the Advancement of Science. Mr. Howard, however, has achieved his own identity as a metallurgist and has added to the reputation of his alma mater, McGill University, already associated with the successful careers of E. P. Mathewson, W. A. Carlyle, W. H. Howard, and the Hamilton brothers.

Standing still for a moment at one end of the converter-aisle I watched the busy scene. On the left, through the open side of the building and on a higher level, I can see a reverberatory furnace, the serried loop-holes illuminated by the heat inside. A stream of red-hot matte is issuing from the furnace and flowing along the quartz-lined conduit on the upper floor. From the little spout at the lower end of this conduit, the matte is pouring into a ladle. When full this

ladle is lifted by a crane, operated by a man in a little cage overhead; it is taken across the aisle and the red stream of matte is poured slowly like wine into the open mouth of a converter, which has been inclined forward so as to aid the transfer. When charged the converter is righted; a burst of sparks and a muffled roar follow the admittance of the blast as the converter is being turned under the hood, which conducts the gases of combustion to the main flue. At another converter a thin stream of slag is being poured into another ladle, which is then lifted by a second crane and taken across the aisle to be poured into a steel launder (50 ft. above the ground), which takes the slag to the reverberatory for re-treatment. The roar from that direction is due to the ignition of the atomized oil, while the similar sound in the converter is due to the violent admission of air. Another insistent sound is the intermittent hissing caused by leakage of air under pressure when the punching-rod is driven through a tuyere of the converter into the liquid charge. There are 24 tuyeres around the rear half of the furnace. Two punchers are occupied in keeping these tuyeres open and in knocking off the 'nose,' or accretion of cold matte, which blocks the opening. These various noises suggest physical energy in action. The sunlight falls silently through the open roof of the building and athwart the blue and yellow wreaths of smoke rising at various points in the foreground. The blue indicates metallic vapors and the yellow bespeaks moisture mixed with dust. These impressions of useful activity are rendered all the more vivid by knowledge of the fact that the smelter stands on the site of a pre-historic Indian village, as proved by the grinding-stones, earthen utensils, and bone needles found in the ground. The volcanic energies of the living are contrasted with the long sleep of the dead.

The difficulties caused by the character of the product delivered from the flotation-mill are shown in the treatment of the Miami concentrate. First comes the wetness, and consequent stickiness, of this material. A reduction in the proportion of water from 17%, as now, to 12% would be an advantage, but the real trouble is not so much the wetness as the fineness of the product, most of which will pass through 200-mesh. A 20-mesh product would be ideal. The difficulties of unloading and distributing have been overcome in some measure by designing special cars and by the liberal use of conveying-belts. The belts passing over the bedding-bins are given a high speed (400 ft. per minute) in order to assist the discharge of the sticky material at the moment when the belt passes over the pulleys either of the terminal or of the tripper. The poking of the concentrate out of the cars is followed by raking it out of the bins. Admixture of crushed lime and 'secondaries' mitigates the stickiness slightly, but not nearly enough. Mr. McGregor, who designed the smelter, says: "I consider it highly desirable to keep such material as flotation concentrate continually moving from the time you start to handle it until you have it landed at the spot where you want it. I think we could have done better to avoid

FIG. G. GENERAL VIEW OF INTERNATIONAL SMELTER

FIG. H. POURING COPPER INTO THE CASTING MACHINE

# American Smelting v. Bunker Hill

## ABSTRACT OF AFFIDAVIT BY E. L. NEWHOUSE

E. L. NEWHOUSE, being first duly sworn, on oath, says: I am 52 years of age, and have all my life been engaged in the mining and smelting business, principally the latter. I was educated technically at the School of Mines, Columbia University, graduating in the year 1886. My professional career has been substantially as follows:

In the year 1886, after graduating, I served as assayer and chemist at the Argentine plant of the Consolidated Kansas City Smelting & Refining Co. Later, for the same company, I was mining engineer, with headquarters at El Paso, Texas. Later I was in charge of the mines and ore-buying business of the same company in the Sierra Mojada mining districts in Mexico. In 1888 I built a smelter and operated the same for the Villa Dama Co. at Nuevo León, Mexico. In 1889 I served as superintendent of the Philadelphia smelter at Pueblo, Colorado. Later I served as buyer and manager of said plant. I came to New York in 1903 as director of the American Smelting & Refining Co. In 1907 I was elected vice-president of the American Smelting & Refining Co. and was placed in charge of their smelting operations. In 1915 I was elected senior vice-president of the plaintiff company.

Since my graduation in 1886 I have been continuously engaged in the mining and smelting business as above set forth, and since 1888 exclusively in the smelting business. For ten years last past I have been a vice-president of the American Smelting & Refining Co. in charge of smelting operations, and have particularly had under my jurisdiction supervision over all contracts made for the acquisition of ores used in our smelting business.

Metals are seldom found in nature (except placer gold) in a pure state. They are nearly always in combination with various other metals. The separation of these metals necessitates the processes known as smelting and refining.

The different combinations of the metal in ores from different mines necessitates different combinations in smelting. Even in the same mine the ore changes. The proportions of silver, of lead, of zinc, of iron, of silica, may vary widely, and any of these changes in the ore are important factors in smelting.

The freight-rate to the smelter and to the final market is an important factor; hence the mine seeks to enrich its product by eliminating the waste and saving in freight. This led to the development of the process of concentration under which, by grinding the ore and agitating it in water and sometimes other chemicals such as oil and acid, the waste matter is eliminated and a product containing a larger percentage of the valuable metals

is obtained. These products are known as 'concentrates' and 'slimes.'

This concentrating process commercially is an important factor both to the mine and the smelter. There is always a loss of metals in concentrating, hence the mine must study the amount of the metal-losses in concentrating as compared with the additional cost of shipping a larger amount of product with an increased freight and smelting charge. The smelter, on the other hand, as a rule, prefers a larger tonnage, but on the whole finds a product, such as defendant's, most advantageous when containing around 50% of lead.

When I was a young man there were few large smelters in the country. It was customary for every important mining district to have a smelter. Such a smelter was usually small in capacity and did what is now considered very expensive and inefficient metallurgical work. Their losses of metals and expense of operations were simply huge. The first thick cream of the richer deposits was being skimmed off throughout the country as district after district was discovered. As soon as the ore in a district justified, a smelter would be established, the expectation being that with the exhaustion of the ores of the mine the smelter would be abandoned and its total cost would be charged up to profit and loss. While the general principles of smelting have not been materially changed, wonderful advances have been made in methods of operation, principally along the line of larger plants, more perfect apparatus, and especially a better combination of ores permitting of better metallurgical results, which means saving more of the metal contents of the ore. Where twenty years ago there were few smelting plants that had cost in excess of three to four hundred thousand dollars, there are now few lead-smelting plants in which there has not been invested at least a million dollars and in many of them a million and a half. The importance of this change in the smelting business is not generally understood outside of the trade, and it has rested upon the following economic reasons:

Smelting is essentially a chemical process carried out on a commercial scale. There must be a combination of the charge of lime, iron, and silica. This is necessary in order to produce a chemical compound by the application of heat, in which compound the true separation of the precious minerals may take place. Gold and silver ores cannot be smelted profitably alone. The amount of gold and silver, especially of gold, is so small that it would be lost in the process. There must, therefore, be a 'collector,' that is, some metal of relatively large volume in the charge which has a chemical affinity for gold and silver. Lead is such a collector. In the smelting furnace

the lead gathers to itself the gold and silver, and through its greater specific weight sinks to the bottom of the furnace. There it is drawn off. This product is known as lead bullion, being a combination of lead, gold, and silver, with some impurities, such, for example, as antimony and arsenic.

Any one mine, or the mines of any one district, rarely, if ever, have the necessary proportions of lime, iron, and silica to enable it to be smelted alone. It follows, therefore, that the smelter must secure the deficient substance from some other course. The main basis of the business of every smelter will be certain ores—the ore of the district or the ore which naturally goes to that smelter because of the lower freight-rate, and the largest tonnage it has under contract. Assume, for example, that this ore is deficient in iron, that is, it requires the addition of iron in some form to make the proper proportion of lime, iron, and silica in the slag. Now, if this iron can be obtained in a combination with precious metals, it is much more economical and commercially better for the smelter than if iron alone (such as scrap-iron) is added to the charge. Hence a smelter which is short of iron will look around for an ore that carries an excess of iron in combination with precious metals. It will treat such an ore for a less amount than it would an ore containing no iron, because everything it saves out of treating is that much saved as against using barren iron ore or scrap-iron. Therefore, every smelter has its own problems, which vary from time to time with the characteristics of the larger part of its ore. If the ores naturally tributary to it have not enough lead to form a collector, but furnish a large quantity of gold and silver ores, then that smelter is short of lead and can pay more for a lead ore to afford the necessary collector. If short of a silicious ore, it will pay more (that is, it will smelt for a lesser charge) an ore containing an excess of silica, and so on for lime and iron. For this reason, it is difficult to compare the different rates of different smelters for the same ore, since the necessity of each smelter for some substances (lead, iron, silica, or lime) may compel it to be seeking that particular ore as a necessary component of its smelting charge and not alone as a source of profit. If a smelter does not make the right metallurgical combination of lime, iron, and silica, or has insufficient lead, its metal-losses in the process will be very great.

In order for a smelter to plan its combinations, it is necessary for it to have its ore-supply known and contracted for. Hence, with the increased size of smelters the custom grew up of making long-time contracts. Having a long-time contract, the smelter was better able to supply its capacity, could better arrange for its metallurgical needs, and for other supplies such as coke, fuel, etc. When I assumed charge of the operations of the plaintiff company, I worked persistently along this line of securing long-time contracts. I found that most mines also found it to their advantage for their own reasons of gauging their production, etc., to make a long-time contract, particularly with a responsible smelter which

would take its entire production. Prior to the organization of the plaintiff company, there were no smelters in the country that were capable of handling an output from one mine in the Coeur d'Alene as high as five to seven thousand tons a month, which is the average output of the defendant, and as a result the Coeur d'Alene mines had several contracts with a number of smelters. These contracts being of short duration, the mine never knew when it would be unable to dispose of its ore and hence might have to curtail its output. Having a long-time contract for an unlimited amount, a mine is always inclined to increase production during times of high prices and to curtail production during periods of low prices, much to their financial advantage.

The principle of long-time contracts has worked out to the advantage of both mine and smelters, and it has revolutionized the smelting business, since now, instead of there being a great number of small smelters doing poor metallurgical work in the vicinity of each mining district, the smelting business has been consolidated at advantageous points selected largely with relation to freight-rates and ore-supply. These are large and expensive plants and the plaintiff has believed itself justified in constructing such plants because its business has been based upon long-time contracts and it thus felt sure of an ore-supply.

The reciprocal advantages to a mine and smelter of the certainty of selling its output on the part of a mine and having a definite supply of ore on the part of the smelter had been felt in the trade and in the Coeur d'Alene district had led to a tendency for either the smelter to become interested in the mine or the mine in the smelter. The Bunker Hill company in order to assure itself a definite output had bought an interest in the Tacoma smelter about the year 1899. This smelter was relatively a small smelter and capable of taking care of or handling about one-third of the production of the Bunker Hill company, but it served its purpose of enabling the company to be sure of a sale of at least that amount of its production. The balance of its production prior to the contract at issue had been sold by the Bunker Hill company to various smelters. Thus, in 1905, when the contract at issue was made, the Bunker Hill company had five smelting contracts with five different smelting companies outstanding: the Tacoma Smelting Co.; the Selby Smelting & Lead Co., at San Francisco; the Ohio & Colorado Smelting Co., at Salida, Colorado; the Pennsylvania Smelting Co., at Carnegie, Pennsylvania, and this plaintiff.

The contracts with the Tacoma Smelting Co. and this plaintiff were at the same price. The contract with the Selby Smelting Co. was \$2 per ton less advantageous to the mine.

The negotiations for the Bunker Hill contract are truthfully set forth in the complaint herein, which I have read and which I believe to be true in its entirety.

I inspected the Tacoma smelter personally; am familiar with smelters, their value and their efficiency. A smelter equally efficient, equally well located, and equally

capable of treating the same tonnage as the Tacoma smelter could have been erected at the time for about the sum of \$400,000 (I do not, of course, include those improvements in the Tacoma smelter for which we particularly paid). As an outside figure, we calculated that \$500,000 was the full reduplication value of the Tacoma plant, and in paying \$4,000,000 for the stock of the Tacoma company, the plaintiff figured that we were paying \$3,500,000 more than we could reduplicate that smelter for. The Bunker Hill people, of course, realized this and the negotiation for the Tacoma smelter was conducted on the basis of buying a going concern that had an established business, which was the main asset transferred and acquired. The transaction was analogous in principle to buying out a well-established newspaper or a well-established and profitable store. In either case the price paid is generally far more than the reduplication value of the actual tangible assets. It is the clientele, the good-will, the established position of the business which gives it, as did the Tacoma smelter in the preceding year of 1904, when it had a similar contract with the Bunker Hill and the three Alaska companies, as a basis of its business, had made certain profits which when capitalized justified the price; but, of course, the price would not be justified unless we were reasonably sure of the continuation of the business, and to insure this continuation we stipulated as a part of the Tacoma transaction that contracts Exhibits B, C, D, and E in the complaint should be executed and become a part of the assets of the Tacoma smelter. Having the business thus assured, we felt justified in paying the price and this situation was thoroughly understood by the defendant at the time. Hence the stipulation that the contract, Exhibit B, should be made, authorized by the stockholders and deposited in escrow to be delivered if the deal went through and to be returned to the defendant company if the deal did not go through. Bernard M. Baruch was acting in that transaction as agent of the American Smelting & Refining Company.

Of these four contracts, thus executed, the Bunker Hill contract (Exhibit B) was by far the more important for the following reasons:

(1). Because the annual tonnage produced by the Bunker Hill was roughly nearly three times the tonnage from the three Alaska companies.

(2). The Bunker Hill contract was for 25 years, while the three Alaska contracts were only for 5 years and thereafter could only be held if this company met the cost of treating the Alaska ores by the cyanide process. It was well understood by all concerned that the probability was that we could not meet cyanide competition as to ores of the character of those Alaska ores, and this, in fact, proved to be the case. At the end of five years the cost to the Alaska companies of treating their product by the cyanide process was so much less than we could afford to treat it that we were forced to give up handling their business. The total tonnage shipped in that five years by the three Alaska companies was about 138,000 tons, while the total tonnage shipped by the Bunker Hill

company for the same period was about 400,000 tons. We all of us understood at the time that the probability was that the three Alaska contracts would only last for the five-year period and this plaintiff so figured it in estimating the value of the respective contracts as a part of the assets of the Tacoma smelter.

The three Alaska companies and the Bunker Hill company are all controlled by the same group of individual stockholders. For many years they have been under substantially the same management. For many years F. W. Bradley, president of the defendant Bunker Hill company, has also been president of the three Alaska companies. For the purposes of the trade the four companies and the Tacoma smelter were all considered as representing one interest, although there were, of course, divergences of actual stock ownership in each of the companies.

The essence and the spirit of the agreement between this plaintiff and the defendant in purchasing the Tacoma smelter was that for a 25-year period the Bunker Hill company should continue to treat the output of its mine substantially as it had been treating it and would ship that entire output when so treated to this plaintiff which had the privilege of routing it to such smelter as it saw fit. From the beginning of that contract in 1905 down to the breach complained of in the complaint, the defendant substantially did this.

When the amendment to the contract (Exhibit B-4) expired in the year 1915 a phenomenal condition existed. The present European war had broken out. During the first few months of the war the lead industry was partially paralyzed, but it soon became apparent that the war necessities (coupled with the condition of anarchy then existing in Mexico and labor difficulties in Spain which shut off the supplies of lead from those important lead-producing countries) would lead to higher prices for lead, zinc, and copper.

As, under the contract (Exhibit B) this plaintiff shares equally with the defendant in any increase in the price above \$4.10 per hundred, it became apparent that the amount received by it on account of smelting defendant's ore would be correspondingly increased, and to deprive the plaintiff of this benefit stipulated for in the contract, the defendant demanded a radical change in the contract, depriving the plaintiff of such benefit, and failing to secure such change, set out to build a smelter at its mine in Kellogg, Idaho. With the completion of that smelter, defendant began to divert ores, concentrates, and slimes that should have been shipped to us under the contract and treat them in that smelter. Instead of as heretofore continuing to make its mine-product into normal grade and shipping to us, and instead of treating the product from its mine as it had treated it during the preceding 25 years of the history of the mine, the defendant began to treat the ore in a different method and manner and to ship the same to its own smelter.

Defendant has intimated directly and indirectly that it intended hereafter to treat all the product from its mine in its own smelter. It has threatened and is carry-

ing out the threat of diverting its mine-product from this plaintiff to its own smelter.

This conduct on the part of the defendant inflicts tremendous and irreparable losses upon the plaintiff in the following respects:

(a) The amount of profit received by plaintiff in the purchase and smelting of ore under said contract with the defendant depends in part upon the current prices of lead and silver which fluctuate from day to day, and the amount of damages that plaintiff would sustain by the failure of defendant to perform its said contract would, if the same be calculable at all, vary practically with each shipment, because of the fluctuations in the market prices, and hence would necessitate a vast multitude of suits, possibly a new suit for each day's shipment since the profit on each day's shipment, if ascertainable at all, would vary with the price of lead and silver on each day.

(b) A smelter can only approximately estimate the damage that is sustained by reason of the failure of a particular mine to ship ore, because of the fact that the ores of each mine are commingled with ores from other mines in order to get the necessary flux, the cost of smelting being distributed to the entire charge, composed of ore from several mines, making it always difficult and at times impossible to ascertain what would have been the cost of smelting if any particular ore had been omitted and some other ore from another mine or other flux substituted therefor.

(c) The ore of the defendant, because of its high lead content, is desirable for the smelting of what are known as 'dry' or 'silicious' ores. Such leady ore is distinctly limited in quantity. Few new lead mines have been discovered in the United States in recent years and old lead mines have their output already contracted for. If plaintiff does not receive from the defendant the mine-product that it is entitled to receive under its said contract, and that the defendant has been shipping to plaintiff pursuant thereto, plaintiff will be unable to smelt a large part of the dry and silicious ores that it has under contract to purchase and smelt, and the plaintiff will be unable to buy additional silicious and dry ores. Its smelting capacity will be reduced and it will be impossible for it to carry on its business to the extent that it has heretofore arranged, and for which its several plants are adapted to carry on said smelting business, all of which have been arranged and based in reliance on the output to be furnished by the defendant company, and they will be unable to use the large amounts of limestone, fuel, and supplies purchased to smelt said tonnages. If plaintiff be not furnished with defendant's ores, plaintiff will be required to discontinue the smelting of much dry and silicious ore that it now has under contract and be liable for damages therefor. All of such expenses, losses, and damages, it will be impossible to estimate.

(d) Though the life of every mine is uncertain, affiant is reasonably well-informed as to the facts, and upon said facts is of opinion that the mineral-contents of the defendant's said mine are such that at the rate of output prevailing since the making of said contract defendant's

mine will continue to furnish the same output for the remainder of the term of said contract, to wit, until February 1930. Plaintiff relying upon said contract and upon its promised performance, has spent large sums of money in enlarging its smelters and equipping them with the most modern devices, so as to be able at all times to handle the product of the defendant's mine pursuant to said contract. If plaintiff does not get defendant's said product, not only will there be an impairment of plaintiff's ability to purchase and smelt other ores which it could and would have purchased were it receiving defendant's product, but the large plants and equipment constructed by plaintiff for the purpose of handling the product of defendant's mine and in which plaintiff has invested several millions of dollars, will become greatly impaired in value, and the amount of the damage resulting therefrom it will be impossible to determine.

(e) Plaintiff, relying upon said contract and the continued performance thereof by defendant, has also greatly increased its refining capacity in order to refine the lead bullion derived from the defendant's mine, and plaintiff's enlarged refining capacity will become idle and greatly impaired in value, and the amount of the damage resulting therefrom it will be impossible to determine.

(f) Plaintiff has built up a large and valuable business in the handling and selling of lead relying upon its said contract with the defendant. This business plaintiff will not be able to supply adequately if it is deprived of the product of defendant's mine. The damage resulting to plaintiff's said business from the breach of said contract in being deprived of the supply of lead promised thereby will be very large in amount and will be impossible to determine.

(g) If plaintiff be required to bring suit at law for the diversion or failure to ship each shipment or lot of ore that may be marketed or otherwise treated or disposed of by defendant elsewhere than with plaintiff, or even if such actions be begun periodically, a great and intolerable multiplicity of actions will result. The defendant in the normal conduct of its business, has been accustomed to ship to this plaintiff each day from 150 to 250 tons of ore, slime, and concentrate in from five to ten railroad-cars. The price of lead and silver often fluctuates from day to day, silver especially having small fractional changes per ounce, which, however, involve considerable sums of money when applied to the quantity shipped by the defendant. The amount of lead and silver in each car may also vary, being affected by many factors, such as the changing contents of lead and silver in the original ore produced from the mine in various parts thereof, the necessarily varying efficiency of the concentrating process, and other factors. Thus the amount of plaintiff's damage might change and vary with each car on each day since plaintiff's profit depends in part not only upon the changing price, but also on the amount of lead and silver it may recover in excess of 90% of lead and 95% of silver. If plaintiff be required to wait until the expiration of said contract in 1930, in addition

to the losses and damages and dissipations of assets of the defendant hereinbefore mentioned, plaintiff will be unable by reason of lapse of time, the death and disappearance of witnesses, and the loss and destruction of evidence, to prove its several causes of action with anything approaching certainty or likely to accomplish the ends of justice.

(h) Said contract like most contracts for similar ores calls for payment for 90% of the lead and 95% of the silver. The remaining 10% of lead and 5% of silver is not paid for, in accordance with a custom based upon the unavoidable loss of these metals in the processes of smelting and refining. A smelter sometimes loses more than 10% of the lead and more than 5% of the silver. On the other hand, if it can make its ore-contracts and combinations successfully, and have the benefit of a high degree of skill and attention on the part of its metallurgists, it may save more than 90% of the lead and more than 95% of the silver and hence increase its profits. It is impossible to prove accurately what percentages of lead and silver in any particular ore is saved, since only accurate knowledge of the percentage saved from the ore of the various mines commingled to constitute the charge in the furnace can be had. If the smelter can rely upon ores being furnished under contracts, it can make its shipments to each smelter conform more to the requirements of each class of ore, and hence it is more likely to save more than 90% of the lead and 95% of the silver of the total ores treated, but it cannot say with accuracy how much of this saving (which means increased profit) is properly assignable to each particular ore treated. Thus plaintiff has made a profit out of this contract by reason of its ability to save more than 90% of the lead and 95% of the silver, but it could not prove in a court in an action for damages exactly what per cent of lead or silver it has been or might hereafter have been able to save, and hence could not show with accuracy its profit in this connection. The quantities of lead and silver saved also fluctuate widely from time to time and are dependant upon many uncontrollable contingencies, such as judgment and skill of the metallurgist, unexpected changes in quality of ore, coke, limestone, etc., unavoidable delays in the shipment of supplies, changes in weather conditions, particularly at East Helena, and many similar factors, which cause the profit made by plaintiff in handling the defendant's ores, to vary widely from month to month and from time to time, entirely dependent of the rise and fall of silver and lead values.

(i) There is a definite limit to the amount of lead ores, concentrates, and slimes to be had upon the market, while from time to time and at various times there is a large demand for such products for the purpose of using the same in smelting other ores, and also directly for the value of the mineral lead, and if plaintiff should be deprived of the said products promised by defendant in its said contract, it will be unable to procure the same elsewhere, and the amount of damages and losses arising from such inability it will be, if not impossible, to estimate, but such damages and losses will be great and in

fact irreparable and necessitate the closing of several furnaces.

(j) Unless a temporary injunction is granted preventing the defendant from diverting its product elsewhere and compelling it to ship the same to this plaintiff, the business of the plaintiff will be irreparably injured for each and all of the reasons hereinbefore stated, which apply to a final injunction. I wish particularly to emphasize the disturbance of the business of the plaintiff which will occur if these ores are lost. It means not alone the loss of this particular ore, but it means the loss in smelting of a large quantity of other ores which the plaintiff can only handle if it has the output of the defendant with which to smelt them. This will be particularly true at our East Helena and Colorado plants. At East Helena we need the defendant's output, which is free from zinc, to mix with the zinky outputs from other mines. If we do not have it, our operations at East Helena will be seriously curtailed. In Colorado we will have to abandon the smelting of considerable tonnages of dry ores, especially those from the Aspen and Creede district. Many of these tonnages we have under contract.

If a final injunction be granted in this case, a great and irreparable injury would be inflicted on this plaintiff if during the interval between the present and the times of a final injunction the plaintiff is not able to smelt these additional ores which require the Bunker Hill ore for smelting purposes. It would have to let that business go. The mines producing this ore would make other arrangements, and if under contract would undoubtedly sue us for damages, and when the final injunction is granted and we could again resume that business, we would find that it was lost and gone to our competitors. I am informed by counsel that it will probably be three to six months before this case can be tried upon its merits. Now, to lose the defendant's ores for from three to six months will entirely upset all our arrangements for that length of time. These arrangements, as I have shown, have been based upon the supposition that we were going to receive the defendant's output.

We entered into the Bunker Hill contract in good faith. We paid a large consideration, as I have heretofore shown. We have arranged our business on the supposition that the contract would be carried out in good faith. We have increased our plants. We have entered into contracts for dry ores. We have entered into contracts for supplies. We have incurred large liabilities and spent large sums of money on the assumption that the defendant would carry out its contract for the life thereof. We cannot now change this situation. If defendant does not ship to us, our business will suffer. We will be made liable for damages on account of failure to live up to our contracts, and we will lose a large amount of business. How much we cannot tell.

The defendant is not in this position. It has not built up a business. It has just started. It knew when it started to build its smelter that we would bring this law suit. We notified the defendant to that effect, both orally and in writing.

## Wasting Ore-Values

Litigation recently begun between American Smelting & Refining Co. and Bunker Hill & Sullivan Mining & Concentrating Co. in the Coeur d'Alene district of Idaho brings to light losses of millions in metal-values through false treatment of Bunker Hill & Sullivan ores over a period of 34 years. It is alleged that when Bunker Hill ores were milled and concentrated by water a colossal blunder was made. These ores contain nearly 8 oz. of silver per ton with 14% lead and 25% iron carbonate. Figuring lead at 13% and silver contents at 7 oz., each ton of ore contains 260 lb. of lead and 7 oz. of silver. Fully 35% of lead and silver and nearly all the iron carbonate were lost in water concentration, whereas were these ores treated by direct smelting as they came from the mine, only 7% of the lead and 4% of the silver would have been lost in slag. On an output of 1000 tons of ore per day, 242,000 lb. lead and 6720 oz. silver should have been recovered by direct smelting. Taking five cents as the average price of lead and 65c. the average for silver during past 34 years that Bunker Hill has been operating, and figuring output of mine at 6,000,000 tons, property should have produced 720,000 tons lead and 40,000,000 oz. silver since it began operations, or a gross output of \$98,000,000. Estimating cost of production at \$6 per ton of ore, cost would be \$36,000,000. This leaves \$62,000,000 for dividends, whereas actual dividends disbursed have been but 25% of this sum.

But the actual results were far different. Instead of the 720,000 tons of lead, which should have been recovered by direct smelting, Bunker Hill got paid for only 450,000 tons. About 230,000 tons was lost through water concentration and the smelting company deducted 50,000 tons for losses in slag. It is estimated that through failure of the Bunker Hill management to build up an up-to-date smelting and refining plant at the start of mining operations 34 years ago, imperfect recoveries through water concentration have cost the stockholders between \$30,000,000 and \$40,000,000. Experts have figured that the greater part of 280,000 tons of lead and 15,000,000 oz. of silver have been lost in the Coeur d'Alene river and a company has now been formed to recover this metal.—'Boston News Bureau.'

The above statement is interesting, and true in part. The Bunker Hill ore never averaged as high as 8 oz. per ton and 14% lead; the average has been about 4½ oz. silver and 11% lead. The total of dividends has not been \$15,500,000, but \$20,370,000, besides \$6,500,000 of operating profit that is represented by cash, securities, plant, and property. In addition the mine has an eight years supply of ore developed and ready for exploitation. It is true, however, that the Bunker Hill company would have been better off if several years ago it had built a smelter to replace the water-concentration plants. On the other hand, it is not correct to suggest that the Bunker Hill could have had its own smelter from the start; not only was this rendered impracticable by the lack of railroad facilities, but it would have been in-

advisable until the progress of the metallurgical art rendered it profitable to erect such an up-to-date plant near the mine as could compete with other established lead smelters in the West.

## Deterioration of Coal in Storage

An interesting bulletin, No. 136, has been issued by the Bureau of Mines, on 'The Deterioration of the Heating Value of Coal During Storage,' by Horace C. Porter and F. K. Ovitiz. It is elaborately illustrated and accompanied with a large amount of tabulated data, from which we believe further conclusions might be drawn with the aid of graphic analysis. The experiments in question have been under way for several years. In fact, they are an outgrowth of the interesting work begun in 1909, under the supervision of the late J. A. Holmes, at that time chief technologist of the U. S. Geological Survey. The object has been to determine the deterioration in coal as a result of storage, a subject of great interest to all power-users who are not so fortunate as to have hydro-electric power at command nor to be able to burn fuel oil. There is given what appears to be a rather remarkable statement regarding which additional explanation would be interesting, that is, that the experiments were made upon small lots "in order to make the tests of maximum severity." Open-air storage was made for the most part in 4-ton to 12-ton lots; though in one case 100 tons of run-of-mine coal were thus stored. Tests were chiefly made with smaller lots in barrels or boxes submerged in fresh water or in salt water. A general summary is presented which states that the tests show that the amount of deterioration in the heating value of coal during storage has commonly been over-estimated. "Except for the sub-bituminous Wyoming coal no loss was observed in outdoor weathering greater than 1.2% in the first year or 2.1% in two years. The Wyoming coal suffered somewhat more loss, 2.3% in the first year, and as much as 5% in three years." This is so greatly at variance with the general experience of engineers that it would seem to be desirable that further experiments be made on a larger scale. It has long been recognized that the deterioration is not excessive when the mass is sufficiently small to prevent increase of temperature from the oxidation of the coal and of the contained sulphur compounds. In consequence it has been the custom of engineers to resort to different methods of ventilation of coal piles in order to check such deterioration. The deductions would seem not to be convincing in the light of the data presented, unless supplemented by confirmation from tests involving much greater quantities.

THE rise of silver has been so unfavorable to American employees in China whose salaries are paid on a gold basis that a movement has been started for an adjustment that will offer relief. For some time salaries have been worth only half their former buying value.

# REVIEW OF MINING

## PETROGRAD, RUSSIA

GENERAL CONDITIONS.—KYSHTIM, SISSERT, TANALYK, RIDDER, SPASKEY.

Since the revolution industrial conditions in Russia have become almost impossible. The transportation department, particularly the railroads, are so badly disorganized that they cannot even carry the grain from the districts in which it is grown to the centres of population in which it is consumed. This is due not so much to lack of cars and motive power as to the low conductivity of the workmen. After

cost price of all metals and all manufactured material has increased from five to ten times over that which existed before the War. Up to now the authorities have taken no active steps to curtail this disorganization and I personally think that they will not be able to do anything in that way until they have established a firm government. On the other hand, I fear that we can expect no real help from Russia, either at the front or the rear, until the people themselves realize that they must do a full 8-hours work for their former 12-hours pay. Owing to these conditions the production of iron and copper has materially decreased and I doubt if the

THE RUSSIAN DOMINIONS

the revolution everything was put on a 8-hour basis and pay on a 12-hour basis. Two months later wages were increased an average of probably 100%, making the cost of an 8-hour day twice as great as a 12-hour day before the revolution. At first the workmen took the stand that the productivity would not be decreased, but practice has shown clearly that the output per man has fallen from 20 to 50%. Necessarily, the unit-cost of all products has gone up. Before the revolution nearly everything was produced on the piece-work system; now, however, the workmen will not allow this kind of work any longer and they insist wholly on day's pay. From statistics now being published it seems that there are roughly 800,000 idle freight-cars in Russia; most of these are idle wholly because they need repair. It cannot be said that there is a shortage of workmen. Owing to the inability of the railroads to transport the necessary food, fuel, and other raw materials, many of the works in Petrograd and other large centres are either completely closing down or cutting down their production, with a consequent dismissal of staff and men. As a result of chaotic conditions, the

total copper production for 1917 will be much more than 60% of that for 1913. Kyshtim is seriously affected and will face a crisis within the next two months. The management has refused to meet the workmen and the workmen claim that they will make no concessions. The Bogoslovsk works have got into financial difficulties. In round figures, they have already this year lost 7,000,000 rubles. On the first of January they had 11,000,000 rubles in bank and on the first of July they had a debt of 4,000,000 rubles; in other words, they had spent, in addition to their ordinary receipts from sales, about 15,000,000 rubles. They have notified the Government that they cannot go on and actual steps have already been started to close their works. I may add that these are the largest works in the Urals, and their idleness would mean a great curtailment of production.—I understand that Bogoslovsk in the last two years has developed a large body of low-grade copper-bearing pyrite, and active steps are being taken to equip a pyritic smelting plant, to which end N. I. Trushkoff is being sent to America.—The Sissert company has completed the prospecting of the Degtiarsky

mine and is now making the detailed plans for a suitable smelter. However, here again, owing to the conditions, all thought of the erection must be postponed.—The Verk-Isetz property, which adjoins the Sissert on the north, seems to be about the only one of the Ural companies that is in a strong position financially. This is mainly due to the good work done during the last few years by F. W. Draper. It was under his direction that this company's smelter was designed and built, and later the mine itself was developed, equipped, and brought up to its present production.—The Tanalyk seems to just about keep even. As soon as one of its shallow deposits gives out a new one is found, but, on the whole, this enterprise does not seem to have a brilliant future.

In the Altai the Ridder has been seriously handicapped by the flooding of the main workings. I understand that the railroad connecting this mine with the Irtysh river is now completed and that the production of concentrate is being delivered to the barges on the river.—The zinc-plant at Ekibastus has been in operation for nearly a year, while the lead-plant was just about to be blown in when acute labor troubles developed.—The Altai concessions of the Russian Mining Corporation have been taken over by a Russian company called The Altai Mines. Although there is a large body of rich ore in the Zyrianovsk mine, no actual steps toward putting up a considerable reduction plant are being taken, owing to the political conditions. Drilling is being done actively and with satisfactory results.—During the last year an entirely new mine, the Byelousovsk, has been developed by drilling, and something over 1,000,000 tons of copper-zinc ore is now considered as proved. In a prospectus recently issued locally by this company, it was shown that 1,400,000 tons of ore had been proved with a net recoverable value of 28,000,000 rubles.—The Atbasar apparently is doing nothing at all; first it had difficulty with labor and later, owing to certain Government regulations regarding the mobilization of the Kirghese, these, to escape military duty, deserted.—I understand that Spassky is again producing, but on what scale, I do not know. There are unconfirmed reports that considerable development of porphyry deposits of copper-bearing ore have been found in these steppes. I believe that this region offers a promising field for other valuable copper deposits.

The platinum production of the Urals has dropped materially, in spite of the high price that the Government is now paying. As is generally known, all the platinum must be delivered to the Government, which is now paying 136,000 rubles per pood; this works out at 314 rubles per ounce for 83% platinum.—The two Bucyrus dredges ordered by the Nicola Pavdo Co. last year are still at Vladivostok and I doubt if they will be in operation before the end of 1919. I am not aware of any other new construction in the platinum region.

The production of gold is declining. As you know, the greatest single producer in Russia is the Lenskoi; as far as can be ascertained, its production for the financial year ended September 31 will be slightly in excess of that for the previous annual period. The Government price on gold is now 11.50 rubles per zolotnik as against 5.51 in normal times. However, as it is not compulsory to deliver gold to the Government, there is a large trade in this product in the open market and the present price at Petrograd for fine gold is about 22 rubles per zolotnik. The dredge ordered by the Lenskoi company is about ready for delivery, but owing to the chaotic conditions in Russia and to the experience of the Pavdo people, it has been decided to store this dredge somewhere in the United States until it can be more definitely foreseen just what time would be necessary to transport and construct it on the Lena.

During this year we have had in Russia, as you probably know, Charles Janin, T. B. Joralemon, H. V. Winchell, J. C.

Ray, and others, looking up business for new American clients, that is, they are new to Russia. I do not know what success they have had, but it only seems necessary to say that they have all left Russia.

## TORONTO, CANADA

VIPOND-NORTH THOMPSON.—TECK-HUGHES.—NIPISSING.

The labor situation at the Porcupine camp shows a marked improvement, and the forces at the leading mines are being steadily increased. The enforcement of conscription has had little effect, as a large proportion of the laborers are either alien enemies or other unnaturalized foreigners, and are not liable to be drafted. Production has apparently taken an upward turn, and with increased milling facilities is expected to show a large increase in the immediate future.—The shareholders of the Newray have ratified the arrangement giving the Crown Reserve a controlling interest in the company and increasing the capital stock from \$1,500,000 to \$3,000,000. Maurice Summerhayes, who has been for some years manager of the Porcupine Crown, has been appointed manager.—The management of the Davidson has arranged for the extension of the electric-power line through its property, thus securing power for the new mill, which should be in operation about the end of the year. The Davidson has lately bought up a number of claims in north-east Tisdale, and now controls an area of about 500 acres.—At the Vipond-North Thompson the shaft will be put down from its present depth of 600 ft. to the 800-ft. level, and arrangements have been made for the exploration of the Thompson-Krist property, adjoining, by running a cross-cut at the 400-ft. level of the Vipond.—Two promising veins have been cut in diamond-drilling on the Bilsky claims, under option to the Apex. The drill-hole is down over 1000 ft.—The southern end of the West Dome Consolidated is to be developed from the Dome Lake workings. Some of the Dome Lake veins continue into the West Dome.

The report of the Teck-Hughes, of Kirkland Lake, for the year ended August 31, shows an adverse balance of \$105,456, and a net impairment at the end of the fiscal year of \$261,926. The extension of the plant to a capacity of 110 tons per day will cost \$30,000, and substantial sums are also needed to carry on operations. A plan to secure the necessary funds is being considered.—Operations at the United Kirkland are encouraging. The shaft is down to the 65-ft. level; it was sunk on a vein which dipped out of the shaft, but two other good veins were cut. It is proposed to tap them by cross-cutting from the 100-ft. level.—Charles O'Connell, for some years manager of the Tough-Oakes, has resigned his position to manage the Boston Hollinger property at Boston Creek; he is succeeded at the Tough-Oakes by D. A. Angus, lately of the Right of Way at Cobalt.—A new gold discovery in the Lightning River district, south of Lake Abitibi, has attracted many prospectors and, according to the last account, about 75 claims had been staked. Several tons of quartz taken from the discovery-vein are stated to assay high. Rock exposures extend over a large area, the basalt formation predominating, with diabase, porphyries, and granites. The field is accessible from Ramore, a railroad station on the Temiskaming & Northern Ontario railway, some 30 miles distant, but the winter will probably check the rush.

The Canadian government has taken action in the matter of the patents on the flotation process held by the Minerals Separation North American Corporation, and has ordered an investigation by the Patents Branch of the Department of Agriculture into the complaint that the corporation was imposing excessive charges for royalties upon the Cobalt mine-owners. The question of whether the corporation is under German influence or control does not come within the scope of the inquiry.—During October the Nipissing mined ore of an estimated value of \$306,167, and shipped products from Nipissing and customs

ore of an estimated net value of \$335,386. Extensions of two branch veins were found at 73 shaft, and the results of the stoping of veins 96 and 102 exceeded expectations. The Chambers-Ferland has found a rich ore-shoot 6 to 8 in. wide on No. 15 vein at the 400-ft. level. The ore is reported to assay 5000 oz. per ton.—The La Rose Consolidated proposes to follow the example of other companies liable to taxation both in Canada and the United States, by dissolving the American holding company and so escaping the United States tax. It also will reduce its capitalization from \$6,000,000 to \$1,500,000.

Plans are being made for the development of electricity at Big Bend falls to supply the Gowganda silver-mining camp and the new district of Matachewan. The falls are capable of supplying between 5000 and 6000 hp., which would be ample for the needs of the district to be served. The project for the development of power at Hanging Stone falls at the south end of Gowganda lake was abandoned owing to financial difficulties. Gowganda has lately attracted increased attention as a coming mining centre owing to the success of the Miller Lake-O'Brien mine, which is now producing silver at the rate of about 8400 oz. per month.

## LEADVILLE, COLORADO

### THE IRON SILVER GROUP.—FRYER HILL DEVELOPMENT.

The Iron Silver Mining Co. has leased the South Moyer mine to William Carson, who for several years has been employed by the company as superintendent. The South Moyer is one of the original properties in the Iron Silver combination and has been a rich producer of lead, silver, and zinc ores. Up to the first of the present year, it has been the centre of the company's activities. With the purchase of the immense tract of ground including the R. A. M., Pyrenese, and Mikado, which the Iron Silver company is now operating through the Mikado shaft, development in the Moyer has been gradually abandoned. The big ore-shoots have been practically exhausted and it was not apparent that development would discover new ore. It is stated that many small bodies of ore are still to be found in the property, making it an alluring venture to a leasing company such as Mr. Carson has organized.—At the Mikado, the Iron Silver company is now producing a steady output of 200 tons per day; half of this is being extracted by the Commerce Leasing company which controls the upper ore-zones where large bodies of zinc carbonate have been opened. The Iron Silver has uncovered large deposits of high-grade zinc-lead sulphide in the lower workings and is steadily blocking out ore.—Following more than a year of systematic development which included the draining of a large area through the Harvard and Jamie Lee shafts and the sinking of the latter 250 ft. through the parting quartzite into porphyry and white lime contact, the driving of numerous drill-holes, and the advancement of long drifts from the shaft bottom, the Leadville Unit has abandoned work in the lower levels of its property on Fryer hill. No ore deposits were found in the second contact where they were expected. The company is now developing the upper portions of its property where many bodies of zinc and lead carbonate have been uncovered. The company also has taken charge of the Denver City property on Yankee hill and is developing it. The Unit is now shipping 50 tons of ore per day. This tonnage will be increased as soon as the railroad siding to the Jamie Lee is completed.—Two of the famous Matchless shafts on Fryer hill are now active. Edward Huter, manager of Matchless No. 1 lease, which is held by a company of Denver men, has completed re-timbering the shaft to its bottom, a depth of 246 ft., and has re-opened some of the old workings, where two small bodies of zinc carbonate have been found. A small tonnage of ore is now being shipped. The shaft is to be sunk another 100 ft. which will put it into the lower ore-zone.—On Matchless No. 2, William J. Burke and associates have prepared to re-timber the shaft and sink

it into the sulphide contact. Machinery is being assembled at the property and work will begin shortly.—F. E. Kendrick, J. C. Strong, William V. Dolan, and John Brady have organized a leasing company and secured control of the Dunkin property on Fryer hill. A new shaft is to be sunk to reach bodies of lead and zinc carbonate that are believed to exist within a depth of 200 ft. Hoisting machinery and surface buildings are being erected. This is the first new shaft to be put down in the district this year.—A. A. Garrett and associates have secured a lease on the Pittsburgh property between the Ponsardin and May Queen on Yankee hill and are erecting machinery at the Blonger shaft. Large bodies of zinc and silver ore have been discovered in the May Queen and Ponsardin making the Pittsburgh one of the most promising ventures undertaken in the district this year.

## MAMMOTH, UTAH

### EAGLE & BLUE BELL.—KNIGHT'S MINES.—NORTH TINTIC.

C. E. Loose returned to Provo on November 14 after a visit to his mining properties in the Tintic district. He reports the Gold Chain and the Grand Central in good physical condition, although both have suffered from the embargoes of the smelting companies and the shortage of railroad cars. As the mines have been unable to ship anywhere near their regular amount of ore, the working forces have been cut down and only half of the regular number of miners are on the payrolls. Considerable ore is piled up at both mines.—Probably no mine in the Tintic district has suffered more as a result of the smelting companies' embargoes than the Eagle & Blue Bell mine which has been unable to ship during 60 days out of the past 75 days. Had it not been for this serious trouble the Eagle would no doubt have closed the year with the best dividend record of any of the Tintic mines, instead of coming second to Mammoth. A considerable amount of new ore has been developed during the past few months. Whenever a drift strikes an orebody the work must necessarily be stopped, as there is no storage room at the mine. The underground workings of the Eagle are in excellent shape for a heavy production when conditions change and the smelters are once more ready to take the product. An immense amount of high-grade ore is awaiting development.—At the No. 1 shaft of the Iron Blossom sinking is progressing satisfactorily. The management intends to sink the shaft to the 2100-ft. level, from which point extensive prospecting will be done. The Colorado Con. company is now driving a drift on the 1100-ft. level to develop a new section of its ground. A drift was sent over into that part of the Colorado from the Crown Point, and the drift which has just been started will cut the same ground 100 ft. deeper.—At the Dragon the No. 1 shaft is being deepened; it is down about 1500 ft., which is equal to 2000 ft. in the Iron Blossom, adjoining the Dragon on the north. A pump has been added to take care of the small flow of water which is lifted through the 1000-ft. level and allowed to flow into the loose formation that exists there. The Iron Blossom continues to send a good tonnage of low-grade ore to the Tintic Milling Co. and the mine is also shipping some higher-grade ore.—In order that work may be carried on below water-level in the Chief Con. mine, pending the question of the new pumping plant, a 500-gal. tank is now being used to bail the water from the sump below the 1800-ft. level. About 80,000 gal. of water per week is being lifted from the mine. One of the largest and richest orebodies which the Chief Con. people has developed in recent years is that which it is now following below the 1800-ft. level.—There is considerable activity among the properties at North Tintic, the busiest being the Lehi Tintic and the Eureka King. The shaft of the latter is down about 250 ft., and when it reaches the 300-ft. level some cross-cutting will be done.

## ASPEN, COLORADO

### DEVELOPMENT AT THE HOPE.

George W. Tower, Jr., and Frederick W. Foote have completed an examination of the property of the Hope Mining, Milling & Leasing Co., and have submitted their report to the officers of the company with recommendations for future development. They advise the driving of an adit easterly from Castle creek into Richmond hill for exploring the Little Annie and Wilmington mines, together with the territory between these properties. This project would reach a depth of 1500 to 2000 ft. and should expose several orebodies in new territory. They state that the workings from this adit, if carefully directed, will cut three known ore-zones; the Little Annie fault, the Silver fault, and the Contact fault. The opening of these zones would assure a sufficient tonnage of ore to justify the erection of a modern concentrating plant. The Hope adit is now 8000 ft. long, six years having been devoted to its advancement; and it is the big enterprise of the Aspen district. The objective of the bore is the territory underlying the Little Annie mine on Richmond hill where good ore was extracted during the early years of the Aspen district and where big ore-shoots are now known to exist. The main shoot in the Annie is opened at various points for a total horizontal distance of 600 ft. and to a depth of 300 ft. In some places it has shown a width of 60 ft. This shoot lies along the Little Annie fault. The Silver and Contact faults, the chief mineralized zones of the district, have not been cut in the Little Annie; and the reaching of these zones through the Hope is the one incentive to the continuation of the enterprise. The Hope company controls a 100-ton mill at the mouth of the Little Annie adit above the Hope adit. The mill is in good condition and contains a crusher, rolls, and 10-stamp mill in the crushing department; screens, Harz jigs, Wilfley tables, cones, and an 80-hp. steam plant for driving the machinery.—The silver-lead ore of the Little Annie contains much barite, and the process of concentration now employed is not adaptable to its treatment. The company also owns a mill-site at the portal of the Hope adit, and, after the ore-zones have been reached, a flotation plant will be erected. Flotation has been tried on Aspen ore similar to that in the Little Annie with good results. The officers of the Hope company are: Charles O'Kane, president; H. W. Clark, secretary; and J. B. Stitzer, treasurer.

## TONOPAH, NEVADA

TONOPAH EXTENSION.—TONOPAH BELMONT.—MACNAMARA.—JIM BUTLER.

The Tonopah Mining Co. during the previous week milled 2700 tons of ore averaging \$10.50. In the Silver Top 67 ft. of development was done and 127 ft. in the Sandgrass. On the 1100-ft. level of the Sandgrass raise No. 1163 continues in ore. Last week the production was 2600 tons.—The Tonopah Extension Mining Co. shipped 21 bars of bullion, valued at \$45,858, which represents the first November clean-up. At the Victor 85 ft. of development was done and 164 ft. at the No. 2 shaft. At the latter shaft raise No. 453 on the 1260-ft. level advanced 31 ft. in ore. On the 1440-ft. level of the Victor east drift No. 604 advanced on 4 ft. of ore, while raise No. 612 continues on low-grade quartz. On the 1680-ft. level the 1600 south cross-cut is being driven toward the C. K. and the Murray veins. East drift 1600 on the Merger vein continues on a 5-ft. face. The production for the past week was 2380 tons.—On the 700-ft. level of the Tonopah Belmont, development has been resumed in east drift No. 721 and west drift No. 722 on the Shoestring vein. Raise No. 16 on the 800-ft. level continues in good ore as well as raise No. 17 on the same level. On the 900-ft. level drift 9021 on the South vein shows 2 ft. of medium-grade ore. Raise No. 72 on the 1000-ft. level, which was started from a

stope on the Rescue vein, shows a 4-ft. face of fair ore. The last week's production was 2440 tons.—The West End mill shipped 29 bars of bullion, valued at \$51,100. The Ohio cross-cut No. 506 has reached the vein, exposing excellent ore, and drifts have been started. Drift No. 531 has been discontinued for the present and a winze is being sunk on the vein. The stope on the 530 drift continues in good ore. Drift No. 1 on the 555-ft. level continues in good ore. Stopes 504, 508, 510, 511, 522, and 523 are all showing good faces of ore. The West End shaft has been re-timbered without interference with the regular work. Drift 717 No. 2 shows a face of low-grade quartz. The output the past week was 1003 tons. The Halifax Tonopah produced 55 tons.—The MacNamara Mining Co. shipped 8 bars of bullion, valued at \$14,700. On the 500-ft. level a raise cut the extension of the Ohio vein exposing 12 ft. of ore. Driving has been started toward the west. On the 300-ft. level the raise out of the winze continues in good ore. On the 725-ft. level stope No. 1 shows 8 ft. of good ore, while stope No. 2 shows a 5½-ft. face. The output the past week was 500 tons.—The Jim Butler Tonopah Mining Co. is cutting a station for diamond-drill work on the 800-ft. level of the Wandering Boy. On the 200-ft. level of the Wandering Boy shaft drift No. 370 has been extended on a 3-ft. face of low-grade quartz. At the Desert Queen shaft raise No. 651 shows a 4-ft. face of good ore. The production for the past week was 850 tons.—The Cash Boy produced 100 tons of ore during the past week, which was sent to the Keswick smelter. With the extension of the drifts on the hanging wall and foot-wall on the 1700-ft. level, a considerable tonnage has been developed.—The east drift on the 1050-ft. level of the Rescue-Eula shows a 2-ft. face of ore. Winze 952 is being sunk on 2½ ft. of good ore.—On the 800-ft. level of the Midway Mining Co., a vein showing 3 ft. of good ore was exposed. A vein showing 15 ft. of low-grade ore was also found on the same level.—The Montana produced 144 tons and miscellaneous 21 tons, making the week's production at Tonopah 10,093 tons with a gross value of \$176,628. The treatment of the tailing 'sweeps' has been suspended for the season. These 'sweeps' average from \$25 to \$30 per ton, and approximately 5000 tons was treated during the summer. A greater part of the tailing was treated at the Belmont plant.

## HOUGHTON, MICHIGAN

### CALUMET & HECLA.—COPPER RANGE CON.

The Calumet & Hecla is shipping an average of 9500 tons of ore per day, and 21 stamp-heads are in use. The Ahmeek shipments are now at the rate of 4600 tons per day. The Mass Consolidated shipments are over 900 tons per day and will be 1000 tons within ten days, as the labor force is being increased. The Allouez shows a slight increase this month and is shipping 2100 tons per day.—The Wolverine also is picking up slightly, producing 37 cars daily, compared to 32 last month.—The South Lake shipped 6000 tons of ore last month.—The Lake shipments were 7300 tons.

The three Copper Range Con. mines, Trimountain, Baltic, and Champion, last month produced 120,000 tons of ore. Of this total Champion contributed 65,000 tons, Trimountain 25,000, and Baltic 30,000 tons. At present Champion is producing 2200 tons daily, Baltic 1300, and Trimountain 900 tons. At Champion this ore-tonnage is considerably lower than the average for last year when it ran about 78,000 tons per month. Underground situation at all properties continues fair; the Champion as usual is producing more than the combined tonnage of the other two and showing a much higher grade of ore. It is the opinion of the best mining men in the Lake Superior district that there has been a smaller increase in costs at the Copper Range mines than at any in the district, except, possibly, the Ahmeek.

## ALASKA

(Special Correspondence.)—On November 18 the 'Mariposa,' belonging to the Alaska Steamship Co., was wrecked on her last voyage of the season to Anchorage from Shakan, Alaska. She struck the rocks of Strait island, 50 miles due west of Wrangell, at night and sank a few hours later. No lives were lost. On October 8, 1915, the 'Mariposa' went ashore near Bella Bella, in south-eastern Alaska, but was re-floated suc-

A. G. McGregor of Warren has purchased a large business block in that city and will establish offices and laboratories there. Mr. McGregor has designed many of the large smelting and leaching plants in the State. In future he will make Warren his headquarters.

## GILA COUNTY

(Special Correspondence.)—The stockholders of the Miami Copper Co. have received notice that dividend No. 19 of \$1.50

THE 'MARIPOSA' ASHORE NEAR BELLA BELLA, ALASKA

cessfully. At one time she plied between San Francisco and Australia for the Oceanic Steamship Company.

Anchorage, November 22.

Considering the disappointing exhibit made by the Alaska Gold Mining Co. for the three months ended September 30, it is not surprising that the stock should have found a new low level. The average value of the ore during the three months was only \$1.01 per ton, and the final net profit was \$8735, which is wholly insufficient to provide a bond interest of \$37,500. Alaska Gold represents a capital investment of \$10,500,000, \$3,000,000 of which is in bonds and \$7,500,000 in \$10 shares. —The Alaska lode-gold mines have shown a decrease in both production and ore value during 1916. The production amounted to \$5,912,736, as against \$6,069,023 in 1915, while the average value fell from \$2.75 in 1915 to \$1.70. The placer mines, on the other hand, showed an increase from \$10,480,000 in 1915 to \$11,140,000 in 1916. This increase is due chiefly to the newly developed Marshall and Tolovana districts.

## ARIZONA

### COCHISE COUNTY.

(Special Correspondence.)—A. Young, secretary of the Green-Cananea, has gone to Mexico City where he will remain for a month. It is believed that he has gone there to take part in the negotiations for resumption of operations in Mexico by American mining interests.

Douglas, November 17.

per share and \$1 per share extra, declared April 2, 1917, and paid May 15, 1917, and dividend No. 20 of \$1.50 per share, and \$1 per share extra, declared June 29, 1917, and paid August 15, 1917, were paid out of the surplus and profits which accrued and were earned prior to March 1, 1913.

Miami, November 24.

### MARICOPA COUNTY

(Special Correspondence.)—The new mineral building at the State fair grounds at Phoenix was sufficiently completed to hold the mineral exhibit, which was by far the best display of Arizona minerals yet exhibited.

Tucson, November 17.

### PINAL COUNTY

The report of the Ray Consolidated Copper Co. for the quarter ended September 30 shows a production of 22,255,598 lb. of copper, against 21,656,342 lb. for the previous quarter. During the quarter 901,300 tons of ore, averaging 1.63% of copper, was milled, and 16,159 ft. of development work done. The mining cost was \$1.169 and the milling cost 88.46c. per ton. The average cost of production was 11.27c. per pound. The regular quarterly distribution of \$1 per share was paid on September 30 and a dividend, of 20c. per share, was paid on July 25. The combined amount totalled \$1,892,614.

### YUMA COUNTY

(Special Correspondence.)—Walcott and Donnely are taking out high-grade ore from the Bullard lease. They have shipped a number of cars. Jones and Hodges, lessees of the

Vindicator property, have shipped 30 tons of ore which gave a return of 20% copper and one ounce gold.—Fleming and Gilland, on the Davis property, are running an adit on a vein to connect with a winze; they are taking out a heavy glance which will run more than 40% copper. The adit is now in over 100 ft. This vein parallels the Black Giant lode and runs through the Ranier property.—The Black Giant is working two shifts in a drift on the Gossan vein. Shaft-sinking has been resumed at the Black Reef. It is intended to sink to the 800-ft. level. The old Socorro company is removing its steam plant to California.

Wenden, November 21.

## CALIFORNIA

### CALAVERAS COUNTY

(Special Correspondence.)—Work at the Calaveras Consolidated mine, near Melones, is proceeding most satisfactorily. The property is owned by the Calaveras Consolidated Syndicate, for which W. J. Loring is manager. The controlling owners are said to be Messrs. Clark and Coolidge of Boston. The property covers 8400 ft. along the Lode, which has been trenched and sampled systematically, disclosing several profitable orebodies, the downward continuation of which has been proved by an adit 400 ft. below the surface and 2160 ft. long. A raise, in ore all the way, connects this adit-level with the surface. Furthermore, a shaft has been sunk at a point 950 ft. from the entrance of the adit, and is now 288 ft. below that level. Drifts are being extended in ore. It is estimated that 241,000 tons of ore is blocked out, and the average assay-value is \$3.50 per ton. A 3-stamp mill for testing this reserve began work in April, and has been crushing six tons per stamp. A new 10-stamp mill began operations in the middle of August, and has continued the test with satisfactory results. In October the two mills crushed 2942 tons for a yield of \$6242 in gold. An additional 10 stamps is now being built. The new plant will include two Hardinge mills and a Minerals Separation flotation unit, followed by Oliver filters. The combined mills will be capable of treating 200 tons per day, and it is expected that the tailing-loss can be kept down to 25c. per ton. The whole plant is driven by electricity supplied by the Sierra & San Francisco Power Co. Included in the property is the famous Morgan mine, once owned by James G. Fair and now owned by his daughter, Mrs. Vanderbilt. The Calaveras property is immediately west of the Melones, which operates 100 stamps, and has been constantly productive for many years, down to a total depth of 3000 ft. It is considered likely that the Calaveras Consolidated will develop into one of the most important mines in the foothill region of California.

Melones, November 22.

### SANTA CLARA COUNTY

Maurice Dieches has been appointed by the Supreme Court temporary receiver for the Quicksilver Mining Co. The company was organized with a capital stock of \$10,000,000, which was issued and is outstanding, to operate the New Almaden and other mines. The listed assets total \$98,000 and the liabilities \$94,000.

### SHASTA COUNTY

(Special Correspondence.)—Bituminous coal has been found at Beegum Creek, near the south-western boundary of this and Tehama county. The discovery was made by D. Noble and Frank Wild of Knob, who have taken up 320 acres. Two seams have been uncovered, the upper one is four feet thick and the lower one eight feet. The 10-ft. parting between the seams carries several thin layers of coal. The coal has been used for welding iron in a blacksmith's shop at Redding.

Redding, November 21.

## COLORADO

### PUEBLO COUNTY

(Special Correspondence.)—Eighty acres of land has been

secured at Pueblo, by the Norcross Chemical Co. as a site for its plant where acids and industrial chemicals will be manufactured. The company proposes to erect at once a 50-ton sulphuric-acid plant and a unit known as the Zurcher unit. The office of the company is in the Ideal building, Denver.

Pueblo, November 23.

## NEVADA

### WASHOE COUNTY

(Special Correspondence.)—John M. Baker, of Alderson, Baker & Baker, of Boston, has examined the properties of the Nixon Nevada and Washoe mining companies for Eastern clients. Mr. Alderson made an examination of the Nixon Nevada about a year ago and in his report expressed the opinion that the numerous veins, from which rich ore has already been shipped, came from a common source and will therefore come together at depth.

Reno, November 21.

### WHITE PINE COUNTY

The thirty-third quarterly report of the Nevada Consolidated Copper Co. shows a copper production of 20,217,673 lb. for the three months ended September 30, as against 20,817,356 lb. for the preceding quarter. During the quarter 1,014,031 tons of ore, averaging 1.46% copper, was milled, 78% of which was supplied from pits and 22% from the underground workings of the Ruth mine. The cost of production was 11.78c., against 11.02c. There was a deficit for the quarter of \$311,051 after payment on July 25 of a Red Cross dividend of 15c. per share amounting to \$299,918, and after payment on September 29 of a dividend of 50c. per share and a capital distribution of 50c. per share amounting to \$1,999,457, or a total distribution of \$2,299,375. There was set aside \$172,144 for plant and equipment depreciation and \$61,000 for ore extinguishment, leaving a net debit to earned surplus for the quarter of \$544,196.

## TEXAS

### LLANO COUNTY

(Special Correspondence.)—Development has just been started on a deposit of graphite near Llano. The property is owned by the Dixie Graphite Co.; Warren May is manager. The equipment consists of a 100-hp. oil engine, a 50-ton crusher, flotation plant, and dryer. From the time the ore enters the crusher until it comes out a finished product, ready for shipment, it is not handled; every step being taken automatically by machinery. The process is so complete that only four men are required to run the plant.

Llano, November 20.

## UTAH

### SALT LAKE COUNTY

(Special Correspondence.)—For the three months ended September 30 the Utah Copper Co. produced 54,999,468 lb. of copper, against 56,403,465 lb. for the previous quarter; 3,439,400 tons of ore averaging 1.306% of copper was treated, and the average cost of production was 10.86c. per pound. The regular dividend of \$3.50 per share was paid on September 30 and a Red Cross dividend of 50c. per share.

Salt Lake City, November 22.

## MEXICO

(Special Correspondence.)—American officials and employees of the American Smelting & Refining Co. in the State of Chihuahua have been ordered to come to the border and eight of the principal officials already have arrived at El Paso. This was announced on November 21 by C. L. Baker, general manager of the company's Mexican interests with headquarters at El Paso. This was done as a precautionary measure and work has been stopped at the Chihuahua smelter pending developments in Mexico.

El Paso, Texas, November 23.

## A. I. M. E., San Francisco

The local section of the American Institute of Mining Engineers will meet on Tuesday, December 4, at the Engineers Club. Mr. Henry F. May, Special Assistant to the Attorney General of the United States, will explain the litigation over the withdrawn oil-lands. Mr. Fletcher McN. Hamilton, State Mineralogist, and Mr. J. H. G. Wolf will take part in the discussion, which promises to be unusually interesting and informing. A large attendance is expected. A simple steak-dinner will be served at 6:30 for \$1 and the meeting will begin at 7:30 promptly.

## War Activities

ALBERT BURCH has been called to Washington by the Bureau of Mines for consultation in the formulation of rules and regulations governing the act relative to the use, distribution, and manufacture of explosives.

THE CALIFORNIA METAL PRODUCERS ASSOCIATION has petitioned the appointment of M. L. Requa, a mining engineer at present employed as the principal assistant to Herbert C. Hoover, as an additional member of the advisory committee appointed by the President for the purpose of devising rules for the guidance of the Internal Revenue Department in the administration of the provisions of the new war-tax law.

Because of the great amount of war work being done by the Bureau of Mines, the Secretary of the Interior has asked six of the prominent chemists of the country to act as an advisory board to the Bureau. The members of this board are: WILLIAM H. NICHOLS, General Chemical Co., New York, chairman of the board; H. P. TALBOT, head of the chemical department of Massachusetts Institute of Technology, Boston; WILLIAM HOSKINS, consulting chemist, Chicago; H. P. VENABLE, head of the chemistry department, North Carolina University; E. C. FRANKLIN, professor of chemistry, Leland Stanford University; and CHARLES L. PARSONS, chief chemist of the Bureau of Mines. The board will discuss and advise upon gas warfare research, the minerals especially needed for munitions, and the recently enacted law for the regulation of explosives.

## Obituary

ARTHUR LAKES died on November 21 at Nelson, B. C., at the age of 73. Born in Cornwall, England, he was widely known in the West as a mining geologist and the author of the 'Geology of Western Ore Deposits.' From the start of the Colorado School of Mines until 1895 he was Professor of Geology in that institution, and in the course of his life he contributed largely to the descriptive geology of Colorado. He is survived by a son, Arthur Lakes, Jr., who has followed in his footsteps as a geologist, but is now in training for a commission at the Presidio, San Francisco.

GEORGE T. HOLLOWAY died on October 24 in London. A graduate of the Royal School of Mines, he established himself in practice as assayer and metallurgist, in 1886. Recently he served as the British government's representative on the Ontario Nickel Commission and was chosen chairman by his associates. Crippled early in life, he made a courageous and successful struggle, becoming a useful citizen, a resourceful metallurgist, and a professional man of the highest standing. He was a familiar figure at the meetings of the Institution of Mining & Metallurgy, of which he was a vice-president and to the discussions of which he was a notable contributor. At the Mining & Metallurgical Club, the Chemical Society, and the Institute of Metals he will be sadly missed. In Canada as well as England he had a wide circle of friends by whom his memory will be honored.

# PERSONAL

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

HENNEN JENNINGS is at the Fairmont hotel.

F. LESLIE RANSOME, U. S. Geological Survey, is here.

OSCAR H. HERSHEY is examining mines near Mina, Nevada.

R. E. CRANSTON has returned to San Francisco from New York.

HOWARD D. SMITH, on his return from Arizona, has gone to Ely, Nevada.

J. T. BROWN, until recently assayer at Cripple Creek, is in San Francisco.

ALFRED SCHWARZ has moved his offices to 1401 Broadway, Joplin, Missouri.

W. R. LINDSAY is superintendent for the Tungsten Mines Co. at Bishop, California.

R. A. KINZIE sailed for Mazatlan on November 27, and will be absent one month.

ATKIN & McRAE announce the removal of their laboratories to 1008 South Hill street, Los Angeles.

STANLEY A. EASTON, superintendent of the Bunker Hill & Sullivan mine, was in San Francisco this week.

EDWIN O. HOLTER and H. P. HENDERSON, of the Jerome Verde company, have returned to New York from Jerome.

A. L. NOLAND has accepted the position of mine superintendent for the United Gold Mining Co. at Granite, Oregon.

E. WALKER, formerly chief chemist for the Butte & Superior, is now metallurgist for the Como Con. Mining Co., at Dayton, Nevada.

WALTER BRIGGS, formerly with the Tennessee Copper Co. and other copper enterprises, is residing temporarily at Berkeley, California.

JOHN W. BULL has resigned, after serving 15 years as superintendent of the Afterthought mine at Ingot, to be succeeded by JOHN LIND.

S. F. SHAW is in charge of operations of the Montañas property in Nuevo León for the American Smelting & Refining Co., which is now under lease.

FORBES RICKARD, JR. has been commissioned second lieutenant in the reserve corps of the Regular Army and expects to go to France on December 15.

CHARLES H. WHITE, recently professor of mining in Harvard University, has opened an office as consulting geologist in the Hobart building, San Francisco.

O. E. JAGER, formerly superintendent of the Cerro de Pasco smelter, in Peru, is in England, where he is on the staff of one of the Government-controlled lead smelters.

GEORGE H. GARREY passed through San Francisco last week after having completed a geological examination for the Tonopah Belmont Development Co. in Colorado.

R. E. ADAMS, superintendent of the Velardeña unit of the American Smelters Securities Co., has returned to Mexico after an absence of several months in the United States.

H. DEWITT SMITH has resigned as assistant-manager at the Kennecott mine, Alaska, to become superintendent of the mine department of the United Verde, at Jerome, Arizona.

ALLEN H. ROGERS, SYDNEY H. BALL, and LUCIUS W. MAYER have formed a partnership as mining engineers, with offices at 42 Broadway, New York, and 201 Devonshire street, Boston.

JAMES G. PARMELEE, research metallurgist for the Granby Con. M. & S. Co., of Anyox, B. C., has accepted a fellowship in metallurgy at the University of Idaho, at Moscow, in connection with the U. S. Bureau of Mines.

Chrome, 34 to 40%, free SiO <sub>2</sub> , limit 8%, f.o.b. California, per unit, according to grade.....	\$0.60—0.70
Chrome, 40% and over.....	\$0.70—0.85
Magnetite, crude, per ton.....	\$3.00—10.00

In anticipation that the Government is likely to fix a price for calcined magnesite, buyers are holding off. There is practically no demand for the crude mineral.

Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.

Tungsten, 60% WO <sub>3</sub> , per unit.....	30.00
Molybdenite, per unit MoS <sub>2</sub> .....	\$40.00—45.00

## EASTERN METAL MARKET

(By wire from New York)

November 27.—Copper is unchanged and nominal at 23.50c. all week. Lead is quiet and firm at 6.50c. all week. Zinc is inactive and easy at 8c. all week. Platinum remains unchanged at \$105 for soft metal and \$111 for hard.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Samuel Montagu & Co. say: There have been several causes for nervous character of the silver market; among these are the facts that the accumulation of orders has been satisfied by an accession of supplies, the difficulty of shipping to neutral countries, the strengthened position of the Indian currency silver reserves, and the freer sales from Mexico.

## ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

June ....	22.20	12.85	9.63	Dec. ....	16.75	11.26	...

The largest zinc-smelting plant in the country has curtailed operations to the extent of two-thirds of its capacity. This smelter has 13,440 retorts, of which only about 4500 are in use this week. The U. S. Geological Survey reports that 64,626 retorts were idle on September 30, and that since then 20,000 have gone out, making a total of 85,000 retorts idle and but 145,000 in operation at the present time. Surplus stocks of spelter amount to over 100,000,000 lb., and it is because of this situation that it is quite improbable that the Government will fix a price for spelter as it has done in copper.

## TIN

Prices in New York, in cents per pound.

	1915	1916	1917		1915	1916	1917
Jan. ....	34.40	41.76	44.10	July .....	37.38	38.37	62.60
Feb. ....	37.23	42.80	51.47	Aug. ....	34.37	38.88	62.53
Mch. ....	48.76	50.50	54.27	Sept. ....	33.12	36.66	61.54
Apr. ....	48.25	51.49	55.53	Oct. ....	33.00	41.10	...
May ....	39.23	49.19	52.31	Nov. ....	39.50	44.12	...
June ....	40.26	42.07	61.93	Dec. ....	38.71	42.55	...

There is practically no change in the tin situation. The Tin Committee has not given out a report, but there is reason to believe that some satisfactory arrangement has been made. The nominal price is 75c. per pound.

Charles Hardy reports no change in the tungsten situation. A small amount of ore has arrived from South America. European buyers are still in the South American market and continue to pay much higher prices than are being paid in New York. Highest-grade wolframite has brought \$25, but sellers are holding for a higher figure. Scheelite is still strong and has been handled at \$26. It is, of course, understood that the price varies with the tungstic acid content and with the proportion of tin and copper in wolframite and of tin, copper, sulphur, and phosphorus in scheelite. Ores containing high proportions of impurities have been sold as low as \$16 to \$17 per unit.

Gold production of Australia for first six months of 1917, compared with 1916 and 1915, was as follows:

	1917	1916	1915
Total fine ounces.....	747,331	850,728	1,005,173
Total value.....	\$15,447,332	\$17,684,548	\$20,777,133

A turn in the tide and an increase in gold production can hardly be expected until labor conditions improve.

# Eastern Metal Market

New York, November 21.

All the markets are quiet and most of them devoid of feature or interest. Outside of copper, which is not ruled now by supply and demand, buying is of small proportions marketwise.

Copper continues to be quoted nominally at the Government fixed price for all brands.

Tin has reached record heights on small sales and is very scarce for spot delivery.

Lead is quiet but firm.

Zinc is dull with a tendency to weakness.

Antimony is nominally unchanged.

Aluminum remains stationary and unchanged.

Fuel scarcity and transportation difficulties hinder full output in the steel industry, which is adapting itself to war conditions with some difficulty. Although it is two months since price-fixing began, market results are scarcely appreciable except in pig-iron, where sales at the fixed prices have been large. In rolled steel there has been some shifting of consumption as well as some reduction. The Government's order for 1,500,000 tons of shell-steel is being allotted, shipments of which are to be finished by June 15, 1918.

## COPPER

There is no longer any such thing as a copper market. A representative of a large dealer said to me yesterday that the public must get rid of the idea that there is such a thing; that one might as well try to call a ball square. The copper 'situation' is absolutely a controlled one, and very tightly controlled at that. Distribution is evidently going along smoothly so far as relates to those having old contracts and delivery is being made in such cases at unchanged prices, but consumers having Government contracts are the ones having the first call. It is acknowledged that firms having Government business that involves the use of copper are receiving the metal at the Government price of 23.50c. per lb., but that the amount is of little consequence marketwise. It is probable that both Lake and electrolytic are being sold for first-quarter delivery at 23.50c. also. How much copper there is to supply the needs of everyone is not known publicly. The jobbing situation is not yet cleared up. Sales of copper bought before the price was fixed are being made at 26 to 28c.—this is acknowledged. It is also admitted that sales of Lake Copper have been made to such jobbers at 23.50c. for delivery in a reasonable time, but at what price they may dispose of this is still unsettled. A satisfactory adjustment of this problem is expected in view of the fact that steel jobbers have been informed at what prices they may conduct their business at levels above the large market. We continue to quote, as nominal, the Government price of 23.50c. per lb. for both Lake and electrolytic.

## TIN

Outside of spot tin the market has been inactive and bare of interest. Spot metal, however, has continued to 'sky-rocket,' and yesterday it put in the shadow its former high record. Small lots were sold yesterday at the highest ever recorded, 77c. per lb., New York, after selling at 74c. on Monday and 73c. on Wednesday, Thursday, and Friday of last week. The scarcity continues pronounced, with no relief in sight. As related before, it is due entirely to the permit situation which allows no metal to be shipped from England unless the consumers' name is specified, thus stripping the market of spot material. The Tin Committee has again made a trip to Washington, but no announcement of a decision has been made, though it has been expected for some time. The entire market

has been held up by an apparent lack of action by this committee, though some are inclined to think that a snag has been struck in the negotiations. No relief is in sight, and even though a solution were reached at once, it would take three weeks or a month for supplies to reach the market. Consumers or holders of tin are not allowed to sell, so no relief is possible from this source. Sales that have been made at the prices mentioned have been in small lots only, or just enough to establish a market. Arrivals this month, including yesterday, have been 1185 tons, with 4100 tons reported afloat. The London market continues to advance. Yesterday spot Straits sold there at £279 10s. per ton, an advance of £5 10s. over sales a week ago.

## LEAD

There is very little to be said about the lead market. The situation is strong, with producers well sold up for November and December, and consumers fairly well cared for. Demand has gradually declined until now it is light. No demand is expected after the heavy sales of the past few weeks, and conditions are entirely normal. There is no pressure to sell, and the market is simply drifting. The outside market is firm at 6.50c., per lb., New York, or 6.31½c., St. Louis, at which prices sales of small amounts are recorded. The American Smelting & Refining Co. continues to quote 6.25c., New York.

## ZINC

The market has again fallen into a lifeless state after a period of a few days of some animation and buying. It was short-lived, and the market is again weak and inactive. A fair business was done last week, some say at prices as high as 8.12½c., New York, but now sellers are willing to part with their prime Western at 7.75c., St. Louis, or 8c., New York, and are doing so, although the actual amount sold is not large. There is little demand, and it is unquestionable that most large consumers are in need of spelter. The market is quoted at 7.75 to 7.87½c., St. Louis, or 8 to 8.12½c., New York, for prime Western for early delivery. Little is heard about price-fixing, although the deliberations of the new Zinc Committee may result in something along these lines. This committee was appointed last week, and is made up of representatives of leading producers. It is conferring with Government representatives on the spelter situation, but the results are not yet available for the public. It is hoped that there will be a clearing of the atmosphere.

## ANTIMONY

Demand continues of small proportions, and the market is nominally unchanged at 13.75 to 14c. per lb., New York, duty paid, for early delivery.

## ALUMINUM

Inactivity continues to rule this market. No. 1 virgin metal, 98 to 99% pure, continues unchanged at 36 to 38c. per lb., New York, for early delivery.

## ORES

TUNGSTEN. There is a fair demand for the various ores at the usual quotations, though South American ores are harder to obtain. Scheelite still commands \$26, or even higher prices, with other grades at \$23 to \$25 per unit in 60% concentrate. Ferro-tungsten is lower, small lots having been sold at \$2.25 per lb. of contained tungsten.

MOLYBDENUM AND ANTIMONY. Molybdenite is quoted at \$2.15 to \$2.25 per lb. of MoS<sub>2</sub> in 90% concentrate on transactions of small proportions. Antimony ore is nominal at \$1.50 to \$1.75 per unit.

# INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

## DIAMOND-DRILL TEST-BORINGS

By JOHN A. WENTZ

At the site of the Great Arrow rock dam, completed about three years ago by the U. S. Reclamation Service, eight miles above Boise City, Idaho, on the Boise river, an entire year was occupied in making test-borings with the Sullivan diamond core-drill, to find a suitable location for the foundation of the dam. Sixty holes were put down to various depths. In 1913 the Little River Power Co. proposed building a modern dam of large proportions across the Little river at Lookout mountain in Alabama. In order that no uncertainty might exist regarding the solidity of the foundation, five diamond-drills were ordered and furnished by the contract drilling department of the Sullivan Machinery Co., of Chicago, and 75 holes were put down, ranging from 100 to 550 ft. deep, at an approximate cost of \$25,000. In 1910, the Portland Railway, Light & Power Co., of Portland, Oregon, had in mind the construction of two large dams on the Clackamas river. The first step taken was to employ diamond core-drills in the selection of sites at which the foundation rock would be sufficiently solid to carry the structure; also at which the least excavation would be required. With the knowledge gained by this drilling, it was possible to carry on the construction to much better advantage and at a lower cost than if the rock conditions had not been developed by this method.

The Chicago & Northwestern Railway owns a Sullivan diamond core-drill, which is used from time to time by the bridge engineering department in selecting suitable locations for bridge-piers. The location for the bridge across the Missouri river at Pierre, South Dakota, was selected in this manner, the test-boring being done during the winter when the drill-shanty could be set up on the ice. The Sullivan diamond-drill was used again in making test-borings at Clinton, Iowa, for the Northwestern bridge across the Mississippi river. Well-drills had previously been used at this site and a profile of the river-bottom drawn up to show the line of solid rock indicated by the borings. Verification of this work with the diamond-drill showed that the well-borings were inaccurate, as they had indicated solid rock at points where the rock was in reality only a projecting shelf. The actual line of solid rock was found to be considerably lower as a result of the core-borings taken with the diamond-drill.

Many other instances could be mentioned to show that modern engineers refuse to take chances or trust to luck in construction work of this type. Numerous cases are on record in which, as a result of insufficient investigation, dams have been built on what appeared to be solid rock, but which events proved to be only thin layers of stratified material with softer beds below. When the full pressure of the

water storage was exerted the dam has given way and been carried down the stream. The city of Austin, Texas, had an experience of this kind a few years ago. The foundation of the dam, constructed for a water-supply, gave way, and the structure was swept away and broken up. In 1907, test-borings by the Sullivan Machinery Co., under the direction of the

DAM ON THE COLORADO RIVER. FRAGMENT OF OLD DAM ON LEFT

SULLIVAN DIAMOND-DRILLS TESTING BED OF LITTLE TENNESSEE RIVER

engineer, Walter G. Fitzpatrick, showed that the dam had been built on a thin bed of limestone, under which was soft shale, badly faulted. After the old dam had been in use for some time, the undermining action of the water advanced to a point at which the entire structure was ruined. On the Missouri

river near Helena, Montana, the Hauser Lake dam, a structure of the hollow-steel pattern, failed from similar causes, as was demonstrated by the diamond-drill, which was extensively used after the failure took place and by means of which a safer

silica-graphite paint for brine-coils, ammonia-condensers, and for iron in other situations where it is subject to corrosive action. Its superior resistance to salt, acids, and mechanical wear is strongly emphasized.

TEST-BORING FOR CHICAGO & NORTHWESTERN BRIDGE, CLINTON, IOWA

The dotted line shows supposed bedrock, as disclosed by borings made with a churn-drill. The solid line is real bedrock, proved by the Sullivan diamond-drill.

location was selected upon which a dam of approved permanence has been erected.

DIAMOND-DRILL BORINGS FOR A DAM SITE, CLAKAMAS RIVER, OREGON

In comparison with the terrible damage and the enormous losses that may be caused by the failure of a dam or bridge due to unsafe foundations, the amount of money required for adequate exploration before the structure is begun is insignificant.

## COMMERCIAL PARAGRAPHS

'Duplex Doings' for October, issued by the DUPLEX TRUCK Co., has a cheery account of experiences on the plains of Nevada, by C. W. Mapes, president of the Nevada Sales Co., of Reno, with some details of the behavior of the Duplex trucks in service.

The WESTERN MAGNESITE ASSOCIATION has been incorporated with R. D. Adams, president; F. G. Wight, vice-president; Frank R. Sweasey, second vice-president; and A. N. Sears, secretary and treasurer. The office of the company is in the Monadnock building, San Francisco.

The JOSEPH DIXON CRUCIBLE Co. has just published another installment of its interesting magazine 'Graphite.' Among other features is an article giving the experiences of D. L. Fagnan, chief engineer for D. Winant, Inc., in the use of

columns. Another publication by the same company, the 'Standard Oil Bulletin,' has just been issued, presenting popular articles on a large number of subjects, including a handsomely illustrated account of cotton production and manufacturing in California, derrick-construction in the California oil-fields, the California oil pipe-line, and a recent tractor-show.

'Leschen's Hercules,' for November, sets forth special and interesting adaptations of the products of the factory of A. LESCHEN & SONS ROPE Co., of St. Louis. A feature of the issue is a beautifully illustrated article on the artistic cement-encased water-towers, 40 ft. diam. and 100 ft. high, erected on Kennedy Heights, Cincinnati. The work was done by the Ferro Concrete Construction Co., and the designs were drawn by J. A. Hiller, the general manager for that concern. There is a double hoisting-tower, equipped with Leschen wire-rope, one side being used for the concrete-skip and the other containing an elevator for the workmen.

Improvements in graphite crucibles, such as those now being manufactured by the JONATHAN BARTLEY CRUCIBLE Co., were credited in a recent issue of the MINING AND SCIENTIFIC PRESS as being the result of experiments by Mr. Bartley. This, we understand, was an error. The new types evolved by that company were the result of work by Lewis H. Lawton, the general manager for the Jonathan Bartley Crucible Company.

The WORTHINGTON PUMP & MACHINERY CORP. has issued bulletin No. S-112, dealing with Snow oil-pumps. It is handsomely printed and beautifully illustrated. A special form of the pump is shown, called the 'California Pattern,' made for the handling of oils of high viscosity, against working-pressures of 600 lb. per sq. in., and to resist shock-pressures of 800 lb. per square inch.

'Powell Grease-Cups' is the title of an illustrated pamphlet issued by the Wm. POWELL Co., of Cincinnati, Ohio. It gives illustrations, in perspective and section, of a great many types, adapted to all classes of machinery from motor-boats to steam-shovels. Each type is fully described, and specifications are given, together with a nominal price-list.

## TABLE OF CONTENTS

### EDITORIAL

NOTES ..... 813

ANOTHER PLEA FOR LABOR..... 814

A miner's view of the contract system; evils and benefits of the method; the importance of competent management and an understanding of the function of the contract. *M. & S. P., December 8, 1917.*

THE FLOTATION OF SILVER MINERALS..... 815

Minerals Separation originally discouraged flotation at Cobalt; J. M. Callow's demonstration of its applicability; special advantages of the method for the Cobalt ores; threats of Minerals Separation against the operators. *M. & S. P., December 8, 1917.*

POTASH AS A BY-PRODUCT OF CEMENT..... 816

Development of potash-production at Riverside, California; objections of orange growers to cement-mill dust resulted in a new industry; by-product potash in the United States may amount to 135,000 tons per annum. *M. & S. P., December 8, 1917.*

### DISCUSSION

A PLEA FOR LABOR

By A MINER..... 817

Contract-work means over-expenditure of energy; does not in practice lead to increased income for the miner; it causes the amount of work to be raised without corresponding pay; not an argument for the I. W. W. *M. & S. P., December 8, 1917.*

SOLUBILITY OF TUNGSTEN

By NEWTON B. KNOX..... 818

Observations in the tin-tungsten mines of Galicia, Spain, on the solubility of wolframite in a kaolinizing matrix. *M. & S. P., December 8, 1917.*

MAGNESITE AND COPPER

By H. W. TURNER..... 818

Note on magnetite with sulphides in the Ural mountains. *M. & S. P., December 8, 1917.*

## ARTICLES

FLOTATION AT COBALT, ONTARIO

By W. E. SIMPSON..... 819

History of attempts to apply flotation to the silver ores of Cobalt; negative opinion by Minerals Separation; successful experiments by J. M. Callow; later adaptations; the Groch and the Ruth mechanisms for flotation; results of treatment at Cobalt. *M. & S. P., December 8, 1917.*

ROAD-BUILDING OVER WET SOFT GROUND..... 824

*M. & S. P., December 8, 1917.*

RECOVERY OF PLATINUM IN GOLD-DREDGING

By JAMES W. NEILL..... 825

Amount of platinum in gold gravel; methods of recovery; causes of loss of the metal; improvements in concentration; outlook for increased production. *M. & S. P., December 8, 1917.*

ZINC FROM LOW-GRADE COMPLEX ORES..... 827

*M. & S. P., December 8, 1917.*

BLASTING-TROUBLES ..... 828

Causes of misfires; inspection of dynamite in storage; method of cutting fuse. *M. & S. P., December 8, 1917.*

THE RUSTING OF IRON..... 828

*M. & S. P., December 8, 1917.*

AMERICAN SMELTING V. BUNKER HILL

AFFIDAVIT BY F. W. BRADLEY..... 829

History of the efforts of Bunker Hill to market its products; relations with the Tacoma smelter and the American Smelting & Refining Co.; terms of the contract; rights of the Bunker Hill to higher market-rates; importance of the Idaho lead production. *M. & S. P., December 8, 1917*

## Large Ball-Mill Plant Driven by G-E Motors

This notable installation of forty-eight electrically driven Marcy Mills at the Inspiration Consolidated Copper Company, Miami, Arizona, must operate 24 hours a day for long periods.

For this, one of the largest installations of its kind in the world, G-E 225 h.p. induction motors were selected. These motors have high efficiency—so important for long period operation—and ample starting torque.

Practically standard construction was selected for these motors, and the selection has been justified during the last two years by an operating record which has been successful in every respect and the basis for large repeat orders.

Hundreds of grinding mills are driven by G-E motors. Among those using these motors are the Calumet & Hecla Mining Company, the Anaconda Copper Mining Company and others equally well known.

**H**OTELS are announcing New Year's Eve entertainments, "bigger and grander than ever," as a Sacramento hostelry says in an advertisement. This is no time for the usual year-end orgy and we hope that good citizens and thoughtful Americans will take pains to express disapproval.

**R**EADERS of this paper will note with pleasure that several firms paid for advertising space in which publicity was given to the raising of a miners regiment, namely the 27th Engineers. The following firms are to be credited with this display of patriotic spirit: Ingersoll-Rand Company, Bemis Brothers Bag Company, Holt Manufacturing Company, New York Engineering Company, Mine & Smelter Supply Company, and Broderick & Bascom Rope Company.

**S**OME time ago we challenged a statement by a well-known geologist in which wolframite was mentioned as a particularly insoluble mineral and hence found abundantly in the outcrop of tungsten veins. Our criticism was confirmed from India, and this week we print in our discussion department a note from Mr. Newton B. Knox giving further examples of the ready solubility of wolframite, especially in the presence of kaolinizing feldspars, in the tin-tungsten mines of Galicia, Spain. It is the free alkali that dissolves the tungsten, and the compounds are highly soluble in water. Alteration to tungstite is rare, and copiapite resulting from oxidation of the pyrite present is often mistaken for it.

**W**E have referred previously to the efforts made by German firms prominent in the rare-metal market to keep from American manufacturers the necessary materials for producing special steels, such as those employed for high-speed lathe-tools. The attempt to corner the market, feebly excused by the transparent lie of moral scruples against war, developed two surprises: the first was an unsuspected abundance of tungsten, revealed by more careful search under the stimulus of soaring prices; the other was the action of England, which in response to the intolerable situation produced by the high cost of these special steels, released large stocks of tungsten to this country. The German pacifists thereupon sought control through obtaining options on every

newly found deposit, or, when this was not possible, by working delay with tempting offers for the output on contract, followed by time-consuming counter-propositions and subtle negotiations over the terms. Meanwhile tungsten was being shipped surreptitiously to the Scandinavian countries for transmission to Germany. Three of the accomplices in this game have been convicted recently in New York, and have been sentenced to pay a heavy fine and serve a year in a Federal prison. These are Fritz Oerundal, Waldemar J. Adams, and R. J. Collin. They were caught red-handed, and the shipment of a considerable quantity of powdered metallic tungsten was narrowly averted.

**L**ETTERS come to us frequently from prospectors, and other worthy developers of mines, asking us to assist them in selling their property or in promoting a mining company. It should be known to our readers that this is quite outside our province. Similarly, specimens of ore are sent to us with the request for an opinion. At one time we maintained a department for such work, which was done for us by a professor in the University of California, but we found it necessary to discontinue the arrangement. Assayers and mining engineers are available for this work. We urge our prospector friends to refer such matters to the nearest assayer or engineer, whose name and address can be obtained by consulting the Professional Directory appearing in each issue of this paper.

**D**ECEMBER 2, which was planned by the Russian I. W. Ws and the Prussian militarists to be the day of a general armistice for the furthering of German domination, was the anniversary of Napoleon's coronation and the battle of Austerlitz. Those events of a previous century should serve to remind the Allies of the fact that Napoleon's domination of Europe was due largely to the obtuseness of the Prussians, Russians, and Austrians in failing to co-operate, allowing Napoleon to smash them in turn, whereas if they had fought unitedly they could have broken Napoleon's power ten years sooner, and thereby spared Europe untold miseries. It was England's bulldog tenacity, and navy, that turned the tide of war then, as now. Reading the records of that era one realizes also that, after all, Napoleon and his

marshals waged war like gentlemen and sportsmen as compared with the princes and generals that are leading the Germans to defeat at this time.

**M**AGNESIUM is used in the new alloy 'magnalium,' not 'magnolium,' to which we referred in a recent issue. In making magnesite cement for gun emplacements, the liquid binder is magnesium chloride. Magnesium is now made, we are informed, by direct reduction from the hydroxide—an important advance in the metallurgy of this metal, the use of which has been intensified by the War. It is used in shrapnel shells to create a vivid smoke by day and a brilliant light by night; it is also used in the star-shells and bombs employed to illuminate the battlefield. Metallurgically magnesium is of great service as a reducing agent, preventing oxidation of aluminum and the other metals with which it is mixed.

**P**LATINUM is regularly recovered as a by-product in gold-dredging along the Pacific Coast. It has been found also in the beach-sands of California and Oregon. In 1911 the platinum coming from these sources amounted to 511 fine ounces, of which about 90% was derived from the gravel deposits. In 1912 the production was nearly the same. Since then the price of platinum has enormously increased, and it is surprising that so little attention has been given to improvements in methods for collecting the platiniferous sand. We suspect that the unwarranted hopes raised a few years ago by some experimenters, who obtained the public ear, may have acted as a deterrent. Many concentrating plants were erected on the beaches of Coos and Curry counties, Oregon, and near Crescent City, California. The results were not brilliant, nor yet altogether unpromising. The subject is brought forward again in a most practical manner by Mr. James W. Neill in an article that we publish in this issue. He explains the causes for the small recovery of platinum hitherto obtained in the treatment of the sands from gold-dredging, and records a series of tests that should encourage others to introduce similar refinements in the operation. He points out that it might be possible, by following such methods, to produce \$150,000 worth of platinum yearly from this State alone.

**R**AILROAD congestion may be overcome in part by local efforts in the construction of highways suitable for motor-trucks, according to Judge R. S. Lovett, chairman of the War Industries Board. This suggestion is of special significance, coming "as it does from the former president of the Southern Pacific Company. He ought to know the limitations of the railroads better than most men, and he understands how much more rapidly motor-trucks may be built than rolling-stock for the railroads. He may have had in mind, also, the remarkable experience of the Long Island railroad. It controls a large and populous area supplying enormous quantities of garden produce to New York. The acquisition of this

line by the Pennsylvania system was regarded as a brilliant stroke; but good highways have almost stripped it of local freight. The business of the island is chiefly conducted by motor-trucks, and the railroad is reduced to dependence upon passenger traffic. Evidently Judge Lovett, through his previous connection with the Southern Pacific, has seen the advantage of the long haul so clearly that he does not fear the invasion of other and more flexible means of transportation in densely populated districts where the short haul preponderates. The highest operating costs per ton mile of freight carried in this country are in New England, and the reason is obvious. The plan to relieve the railroads by construction of more highways as an emergency war-measure is commendable, and its results will prove beneficial for all time to the public, to the makers of motor-trucks, and to the railroads themselves by increasing their operating profits.

## Another Plea for Labor

We publish another letter written from the point of view of the laboring man. Such letters are welcome, and they are a distinct compliment to this journal in that they indicate the belief of the miner that we endeavor to be fair in discussing the vital problem of industry. We should like to see such letters as those of Mr. J. F. Harrington and Mr. 'Miner' answered by one or more mine-managers. A friendly discussion before a neutral chairman, as it were, would be useful in promoting a better understanding between those chiefly concerned. The difference between our own opinions, as previously expressed, and those of Mr. 'Miner' are due to the different directions from which we come to the subject of debate. We are well aware that the contract system is often abused. In our issue of July 7 we said that "the contract system is fair to all concerned and it is the only system that upholds the self-respect of the working-man; we believe, however, that it is not always fairly applied and that it then becomes vicious. Here we come to the root of the whole matter; fair dealing as between men." The system sustains the miner's self-respect, because when working on contract he can feel that he is working for himself, on his own account, being paid in proportion to his effort. The trick of shifting a contract crew as soon as they are making big money is a dishonesty of the cheap and nasty kind; the superintendent that does such a thing is little better than a thief; and he is inefficient, because such tactics fail in their purpose, which is to lower the cost of operations. When the superintendent plays such tricks the best men leave the mine. Where properly used the contract system is a means not of lowering the pay but of raising it, by offering a premium on results—not necessarily such excess of exertion as to kill a man's vitality. In a similar way the 'piece-work' system is abused. Employees are paid, say, so much per hundred units when a thousand will represent a reasonable day's wages; if they do 1250 they receive 25% more pay; they are encouraged to raise their

output to 1500 units, whereupon 1250 is made the basis of the wage-scale, and they are driven to an over-exertion that is killing to those of average strength. It is to this system of driving that Mr. 'Miner' refers. We agree that it is bad economically, as well as inhuman. So also a manufacturer will appoint an agent on a small salary plus a commission basis; as soon as the agent has established a good local business the manufacturer dismisses the agent and substitutes a direct representative, who takes all the benefit of the pioneer work done by the previous agent, but at a lower cost to the manufacturer. Such practices are dishonest in spirit, however legal, and tend to undermine that good faith which is essential to honest business and honorable living. In the end such methods are demoralizing to all concerned, and more particularly to the democratic ideal on which this Republic is based. Let us return to our immediate subject. Our own experience has been that the contract system, when fairly administered, attracted the best miners, but to establish it successfully it was necessary to set such prices as would permit the men to earn considerably more than the standard day's pay. It does not matter how many dollars a miner gains, but how many dollars it costs to break ground per foot of cross-cut or drift, or per ton of ore stoped. Only an inexperienced and stupid superintendent will cut the price as soon as the men make a little extra money, that is, lower the rate per foot when he lets the cross-cut or drift at the beginning of the following month; for I do not suppose him to be so dishonest as to break his contract with the men, no matter how much money they may be making, by discontinuing work during the month for which the contract is let. The trouble is that many superintendents do not know how to judge ground, so they let contracts at figures that are considerably too low or too high; in fact, they make a guess, and if they guess to the disadvantage of the company they try to remedy the blunder by stopping work on the misjudged contract. A competent superintendent can judge ground better than the men—that is one reason why he is 'boss'—and he should use his superior judgment in an effort to be fair. If he does, the men will have confidence in him and when in places the ground changes suddenly it will be recognized on both sides as a factor of error that is corrected in the long run so as not to work persistently to the advantage or disadvantage of either the men or the company. As to shirking, to which Mr. 'Miner' refers, shirking is never a virtue, even for your brother's sake; we demur to that idea. A self-respecting man will use his strength and intelligence to good purpose; he will delight in being effective. To slack in order to make it easier for a weaker or lazier comrade is an idea that does not appeal to us at all. The first thing a truly honorable man desires is to be honest with everybody; to deliver the goods; to give a fair day's work for a fair day's pay. The workman is worthy of his hire; the employer is entitled to a given amount of labor in return; it is an unwritten contract between two honest men. Slacking is not self-

preservation; it is self-degradation; when it becomes a principle of conduct it degrades the cause of labor, just as the breaking of the unwritten code of good faith in the fulfilment of a contract degrades the cause of capitalism; both alike stultify honest industry.

## The Flotation of Silver Minerals

Flotation is predominantly associated, in the United States, with the metallurgy of copper, and after that with the concentration of zinc and lead. The recovery of silver has not been featured, so that it is well to furnish information concerning the work done at Cobalt. We are enabled to publish a timely and useful article by Mr. W. E. Simpson, previously honorably identified with cyanidation in Mexico and other countries. In his article he records the fact that the Minerals Separation people discouraged the application of flotation to the silver ores of Cobalt. This agrees with our own information. It was from Mr. J. M. Callow that the successful initiative came. In March 1915 he made his first test, and in the September following he sent one of his technicians with the necessary equipment to establish an experimental plant for the Buffalo Mines Company. He re-crushed the tailing from the old mill, reducing the pulp to a product that left only 5% on a 200-mesh screen. In June 1916 another experimental plant was erected under Mr. Callow's directions at the McKinley-Darragh-Savage, where the overflow-slime was subjected to flotation, with satisfactory results. These experiments led to the Buffalo Mines Company building a 600-ton plant, which is yielding a 1½-ounce tailing on a heading assaying 8 ounces per ton, and giving a concentrate containing 350 ounces of silver per ton. The general practice of the district has been described by Messrs. Callow and E. B. Thornhill in Bulletin No. 62 of the Canadian Mining Institute. It will be noted that at Cobalt the flotation process does not replace, but supplements, ordinary water-concentration. The new process serves chiefly to save the friable silver minerals and fine metallic silver that escape the older processes. Whereas fine grinding causes loss from the jigs and tables, it favors the success of treatment by flotation. This is also the story of copper metallurgy. By the way, we venture to draw attention to the fact that it is unscientific to distinguish between flotation and table-concentration by speaking of the latter as a 'gravity' process. Flotation is not independent of gravity; on the contrary, the rising of the bubbles, bearing their freight of pulverized mineral, is an operation in which gravity is the chief agent; only it happens to be upward, instead of downward, because the mineral-laden air-bubble weighs less than the water it displaces. Fortunately, the major part of the silver in the ores of Cobalt is present in native form, which is quickly responsive to flotation, if untarnished. We suggest that this proviso explains the discrepancy between experimental work and large-scale milling, particularly on old tailing-dumps. Mr. Simpson rightly emphasizes:

the relatively low cost of a flotation equipment and the relatively small space that it occupies, while he recognizes the disadvantage, as compared with cyanidation, of an unfinished product, namely, a concentrate that has to undergo further treatment before merchantable bullion is forthcoming. On the other hand the concentrate produced by flotation is purer than that obtained on table-machines, that is, it contains less arsenic, nickel, and cobalt—this, however, appearing to interfere with the extraction of by-products from which the smelters win an incidental, but most satisfactory, profit. In fact, the marketing of the flotation product has been the chief obstacle to the general adoption of the process at Cobalt. The smelters have levied arbitrary charges, which, with the railroad freight, have made a distressingly big hole in the gross value. Evidently the future extension of flotation depends upon the development of a successful local treatment for the concentrate. Mr. Simpson gives an outline of the methods that have been tried, both with and without previous roasting. We look forward to publishing further details as experimentation advances to a successful issue. This necessary work, we regret to add, is hindered by the threats of the Minerals Separation company and by the litigation incidental to an attempted collection of royalties. On this phase of the subject we have dwelt frequently in these pages. Suffice it to say that we hope the mine-operators of Ontario will succeed in obtaining the protection of the Canadian government so that the process-mongers may be brought to a reasonable state of mind and be prevented from exercising a tyrannical embargo.

## Potash as a By-Product of Cement

When the orange-growers of southern California brought action against the cement-makers of Riverside county in order to compel them to abate the nuisance of a fine fume, which volatilizes in the air and settles upon the foliage, causing injury to the citrus trees, they little thought they were doing a service to the owners of the plants and, incidentally, to the country at large. With the option of either abating the nuisance or of closing their plant, the Riverside Portland Cement Company installed the Cottrell apparatus, which effectively prevented the escape of fume into the atmosphere. In the fume thus arrested from 4 to 12% of potash was found. It is not so long ago that Dr. Wilhelm Friedrich Ostwald announced to the German nation that they held the trump card against any post-war trade-war, for by cutting off the only known large deposit of potash from the enemy—that of Strassfurt—Germany could dictate what they should and what they should not eat; potash being, it is needless to add, one of the prime essentials of plant life and, therefore, a necessary constituent of productive soil. Leaving aside the question of post-war trade-war, potash has become an urgent necessity, and some of the best brains in this country have been at work to find a means of supplying the want; and here, through the veriest

accident, one might say, a considerable source of supply has been discovered.

To make things more clear it will be well to consider roughly for a moment the manufacture of portland cement. The necessary constituents are lime, silica, alumina, and oxide of iron. In this country the lime is provided generally in the form of limestone and the other constituents as clay or shale. Most clays contain a small proportion of potash, especially when they are derived, as they often are, from the decomposition of granite containing potash feldspar; but other substances, such as feldspar itself, equally as well as clay or shale, would provide silica and alumina for the cement and, at the same time, would give a much larger proportion of potash to be saved as a by-product. The limestone, and the clay, shale, or feldspar, are ground finely, and thus intimately mixed are burned to a clinker in a large rotary kiln, and it is in this burning that the greater part of the potash becomes volatilized and is eliminated from the cement-clinker as fume. Experiments at Riverside have demonstrated that the addition of a small amount of fluorspar to the raw 'mix' greatly assists the volatilization of the potash, and by this means, and by careful attention to other details, the extraction of potash has been so improved that 70% of that present in the 'mix' is leached from the fume by water and converted to sulphate, in which state it is marketed. Care has been taken, also, to so select the raw material that it shall contain the greatest quantity of potash compatible with the manufacture of a high-grade cement. The efforts of the management have been crowned with such success that today the Riverside plant presents the curious anomaly of being not a cement plant that produces potash as a by-product but a potash plant producing cement as a by-product. In other words, potash is the main product sought at the Riverside plant, and, in order to make as large an output of that substance as possible, more cement is being made there than is needed to supply the demand. The present output of the plant is about 5000 barrels of cement per day, and six pounds of potassium sulphate is recovered for every barrel of cement made. The surplus cement will be stored in the form of clinker until the end of the War, when potash prices will tumble and cement will again be the principal product. It is pleasing to note, too, that although the evolution of the process has been made possible by the abnormal price of potash, it is claimed that potash can be made at a profit when that material reverts to pre-war prices. The operations at Riverside have not escaped the attention of cement-manufacturers in other parts of the country. Many cement-makers have added dust-saving plants, and the only reasons to prevent their becoming standard is the high cost of structural material and the lack of assurance that the present price of potash will be maintained. Based on the production of plants already in existence, the estimate has been made that if dust-saving devices were adopted by all the cement-plants in the country it would result in the production of about 135,000 tons of potassium sulphate per annum.

## A Plea for Labor

The Editor:

Sir—Your answer to J. F. Harrington in the November 17 issue aroused my interest, and I feel it my moral duty to say a few words in comment. True, I am not trained to produce articles grammatically correct, and in literary style, as I have grown gray in the occupation with the shovel, pick, hammer, drill, machines, and all that; and those playthings are not conducive to such qualities. Yet I feel confident that the meaning of these lines will be understood by the esteemed editors, regardless of the grammatical errors and faulty English of this missive.

You say, in your editorial, that contracting is a means of developing team-work, etc., at an agree price, and with such speed as to yield the worker more than day's wages. Mark well the word 'speed'! Anyone who has had some experience will know that the extra speed almost invariably is coaxed, cajoled, coerced, or driven out of the men's backs. The extra speed, I say, is the result of the extra energy exerted by the men; in fact, the efficiency engineer's problem seems to begin and end right there. This is not what he has been taught in college, as I understand it, but that is the way it works in practice—so with the contracts. The amount more than day's wages is nearly always at the price of over-exertion, and when the workman's energy is fagged out, he soon falls short of the mark, or, slowing up in one way or other by failing health, he, like the mule, is turned out to grass, with the difference that the mule is turned into its owner's pasture, and the man is turned into the public feeding-ground. They have to foot the bill when picking along the roadside for him is no longer possible. True, if he is knocked out suddenly, he is taken to the county hospital, usually fairly well taken care of, but that is not the case, however, when the workman suffers from general deterioration of health. But—back to the contract again—I have been told time and again that contracts are for the purpose of raising the pay for good men, and to get work done more speedily. Granting the latter to be true, while the former is only nominally so, or I may say, only temporarily so, it is more often told for the purpose of deceiving, which is equivalent to a lie. Knowing to my regret that by using all the ingenuity I possessed, and with intimate co-operation and team-work, and exertion of energy enabling me and my partners to get more than day's wages for a short time, if the time or distance or both to be driven were specified by written contract, it would last that long; otherwise if no

written contract existed, we would be told that the place where we worked would be shut-down, and we would either be laid off indefinitely or sent to some remote corner of the mine to work for day's pay, or else a 'hard' contract, obviously for the purpose of keeping us away from the former place where we worked on contract, that place meanwhile being let on contract at a much lower figure, usually at such a price as would give day's pay by doing the same amount of work as we did when we worked there. If the new team failed to come up to the scratch, they would get fired and another lot would be given a contract, only to meet the same fate. This would go from bad to worse until the ground changed to relieve the situation, or else the bosses would raise the price a trifle, so that the contractors could by utmost exertion make the standard day's pay. This is the way the 'contract system' works. Not raising the pay of good men, but lowering the pay by raising the amount of work for the day's pay at the rate prevalent in the district. I can name the mine and the officers, etc., where a number of definite cases occurred similar to this, but that is not necessary to illustrate the point in this argument; besides it is in the past. I am convinced that this is the way it works in general in all the big mines where contracting is practised, and I will pit my experience, to wit, in Alaska, British Columbia, Washington, Idaho, Montana, South Dakota, Colorado, Arizona, Old Mexico, and some of the continent of Europe against any argument, no matter how nicely put up or well delivered, to the contrary, as to the result, namely, doing more work for the same pay, for that is what it finally amounts to. You may say, with the majority of others, that it is the men's own fault for setting the pace. True, but if you are candid you will also admit that any normal person, not spoiled by adverse experience, delights in doing and getting results, and this trait should not be manipulated to the possessor's injury. But alas, he soon learns that it is to his own and his fellow's detriment; to the benefit of whom? Is it not a natural consequence then that the worker will try to do less than his best; in fact, self-preservation compels him; so shirking becomes a virtue, in consideration for his fellows, who may be less fortunate as to physical endurance and aptitude.

No, my dear Mr. Editor, most contracts and bonuses can consistently be compared to a cartoon appearing in one of the comic papers some time ago, where a negro hired a team of mules to haul a load to town. Wanting to economize on mule-feed, he conceived the idea not to feed the mules, but to tie a bundle of hay on a stick, and

nail that stick to the wagon-tongue, so the bundle would be in front, and barely out of reach of the hungry animals. Eventually they would, by hard pulling, flatten the collars enough so they could reach and get a bite of the hay once in a while. I venture the opinion, Mr. Editor, that those animals did team-work toward getting that hay, and further, that the negro, swelling with pride of superiority, would prod the animals to see if possible to get more speed out of them. The animals in their state of temper would exercise the heaven-born right, and use their natural weapon of defense.

As to the I. W. W., I have no argument with you; suffice it to say that an article written by Professor Parker of Washington University, in the 'Spokesman Review,' a few days ago, hit the nail fairly on the head. He says the I. W. W. is a symptom rather than a disease.

Wallace, Idaho, November 24.

A MINER.

[The writer of this letter states that it was not intended for publication, but that, if we choose, we may publish it. We do so because it is the sincere expression of opinion from a thoughtful man. In discussions of this kind we care little about grammatical errors or lack of style; these are small matters as compared with sincerity. The one man to whom these columns are closed is the one that talks through his hat or adopts a pose in order to get into print. Mr. 'Miner' is heartily welcome to the space taken by his letter; he is as sincere as Mr. 'Editor' and he knows as much about his subject. The article to which reference is made above is 'The I. W. W.', by Carleton H. Parker in the November issue of 'The Atlantic Monthly.' Evidently it was reproduced by the 'Spokesman Review.' We agree with our correspondent that it hits the nail on the head.—EDITOR.]

## Solubility of Tungsten

The Editor:

Sir—In your issue of September 1 there appeared an interesting letter by Mr. J. Coggin Brown on the 'Solubility of Tungsten.' Mr. Brown refers especially to the Tavoy district. The occurrence of wolfram here, at the Phoenicia mines, tends to support your and Mr. Brown's views regarding the rapidity of the solubility of wolfram over cassiterite. In the Phoenicia mines, which are in Galicia, north-western Spain, the ore occurs primarily in three parallel quartz veins cutting across chlorite-schist which has been intruded by a series of pegmatite dikes varying in width from one to twenty-five metres. The minerals of the ore vary from two parts of cassiterite and one of wolfram to equal amounts of each mineral. Wherever the veins pass through the dikes more cassiterite than wolfram is encountered; indeed, in those dikes where the feldspars are highly kaolinized only crystals of cassiterite occur. The crystals vary from those of a beautiful ruby-red, about the size of a mustard-seed, to large gray pyramids and prisms about the size of walnuts and looking not unlike the old-fashioned rock-candy. Some wolfram is found in the granite, but as a rule the veins crossing the schist yield a larger pro-

portion of wolfram than those passing through the granite. It would appear that in the kaolinization of the feldspars the wolfram has been dissolved. On this mine many surface workings have the appearance of extreme old age and are locally attributed to the Phoenicians. On the dumps of these ancient workings—dumps of surprisingly limited extent—more wolfram than tin is found; due possibly to the fact that wolfram was previously discarded as waste. It is, however, interesting to note that wolfram on the surface is most frequently found in the form of large single detached crystals quite free from quartz. These crystals may be the reject of ancient cobbings, or, what is more likely, they have decayed out of their quartz matrix and represent the beginning of chemical decomposition.

I have never found single detached crystals of cassiterite. Let me say, in passing, that the wolfram here occurs as a very pure mineral, our concentrate averaging 73% of  $WO_3$ . At the Mawchi mines, in the South Shan States, Burma, a tin-wolfram property, my samples of the pits in the detrital deposits below the veins showed a greater proportion of tin over wolfram than samples taken from the veins themselves. Unfortunately my notes relating to these samples are not here and I am unable to give exact figures.

NEWTON B. KNOX.

Noya, Coruna, Spain, October 14.

## Magnetite and Copper

The Editor:

Sir—Referring to the note by Mr. Edgar Hall on the occurrence of magnetite in copper ores, in your issue of October 6, I would say that in looking through the Kalata copper mine in the Ural mountains in 1911, I found some black and yellow banded ore. This, on closer examination, proved to be magnetite with iron and copper sulphides arranged in layers, all these minerals apparently being original. The chief sulphide was pyrite with perhaps 2% of copper in the form of chalcopyrite.

San Francisco, November 30.

H. W. TURNER.

THE reaction producing basic copper sulphate was stated in the article on 'Heap-Leaching of Copper-Sulphide Ores,' MINING AND SCIENTIFIC PRESS for November 24, 1917, p. 755, as  $CuSO_4 + CuO = (Cu_2O)SO_4$ . That was incorrect as regards the form of presentation of the molecule. The compound produced is the basic cupric sulphate,  $CuO \cdot CuSO_4$ . [DE KALB.]

SPELTER purchases by the United States government since April have amounted to 58,128,500 lb. For grade A the price, f.o.b. New York, has ranged from 11½ to 13½c. per pound, for grade B from 11 to 13c., and for grade C from 8.75 to 9c. About 40% of the spelter used by the Government is of grade B, under requisitions from the Army and Navy departments. It has been proposed by the Zinc Committee to restrict the production of the metal as a means for steadying the market.

THE DOMINION REDUCTION WORKS, AT COBALT, USING THE CALLOW FLOTATION SYSTEM

## Flotation at Cobalt, Ontario

By W. E. SIMPSON

**SYNOPSIS.** Flotation has proved a useful auxiliary in the treatment of silver ores, and is now in operation at practically every producing mine in the Cobalt district. Mines originally equipped with plants for gravity concentration have bettered their recovery as much as 5 to 15% through the addition of flotation-units, while the added cost is from 5 to 15 cents per ton. With the all-sliming process (grinding in cyanide solution), extensive experiments indicate that when recovering the refractory minerals by flotation, the usual revenue is maintained or improved, and that the consumption of cyanide is reduced one-third. The chief difficulty with flotation lies in the disposal of the concentrate, marketing to distant smelters being expensive and local treatment not yet having proved satisfactory. Threatened litigation by Minerals Separation, Ltd., is also seriously embarrassing metallurgical progress in the Cobalt district.

**HISTORY.** The earliest application of the flotation process to the treatment of silver ores at Cobalt dates from 1910 when some small-scale tests were made in the laboratory at the Coniagas mine, to note the effect, if any, of violently shaking representative samples of mill-pulp to which had been added a few drops of oil. No commercial importance was attached to the results obtained in these simple experiments and the matter remained

in abeyance so far as that mine was concerned until quite recently.

The next attempt was made in 1914, when a former employee of the Minerals Separation company constructed an experimental unit at the Temiskaming mine and demonstrated the feasibility of profitably treating the fine tailing, then being run from the concentrating mill to the waste-pile. The litigation ensuing over the use of flotation acted as a deterrent to the continuance of experiments.

While these tests were being conducted, a sample of slime, representative of what may be now called flotation-feed, was sent by the Cobalt Reduction Co. to its consulting engineer in London to determine whether the flotation process could be introduced successfully in the Cobalt district. The tests were made in the laboratory of Sulman & Picard, metallurgists for Minerals Separation, Ltd., and the results were as follows: The sample assayed 5.5 oz. silver per ton, and the products obtained were a concentrate assaying 43.5 oz. containing 57.11% of the silver in 7.3% of the weight of the original slime, a final tailing assaying 1.99 oz. per ton with 24.88% of the gross content left in 69.15% by weight of the slime, and a middling containing the rest. Alf. Tellman, who signed the report, concluded by saying: "I believe

that if the slime can be successfully treated by cyanide you will be able to make more profit than with flotation."

The serious adaptation of the flotation process to the Cobalt ores really started when T. R. Jones, manager of the Buffalo Mines, after conducting an extensive experimental campaign, installed the first treatment plant to operate on a commercial scale in October 1915. This unit employed the Callow type of machine and had a capacity of from 50 to 75 tons per day. So satisfactory were the results that additional plant was immediately erected, bringing the total capacity to 600 tons per day in September 1916.

The first flush of success led to the statement by enthusiastic operators that flotation would entirely replace the gravity method of concentration, completely displace the cyanidation of Cobalt ores, and revolutionize the established practice of metallurgy. Further experience, however, has called for a modification of these views. A satisfactory recovery of the silver-bearing minerals by flotation is only obtainable from material in a fine state of subdivision and the tendency now is to apply the process to the treatment of slime and to such portions of tailing as may be sufficiently rich to warrant the additional expense of fine grinding.

**THE ORE.** The Cobalt orebodies are aggregations of veins formed, apparently, by the deposition in regular succession of various minerals in zones of fracture in the country-rock, which may be either slate or conglomerate. No actual walls define the limits of these orebodies, but the gross width of mineral matter extractable at a profit may reach 20 or 30 ft., although the veins individually are seldom more than a few inches wide. A geological diagnosis indicates the deposition of the minerals in the following sequence: Smaltite, niccolite, calcite, argentite, native silver, and, lastly, bismuth; copper also occurs in traces. The ore, therefore, is decidedly complex.

About 90% of the silver of the district occurs in the form of the native metal, a fact that did much to simplify metallurgical operations in the early days, and permitted many mining prospects to develop into wealthy producers without any capital outlay beyond that required for the purchase of a few tools. This metallic silver frequently is found in slabs six to eight inches thick and weighing thousands of ounces, but much of it occurs in a state of subdivision so minute as to necessitate pulverization of the ore to pass a 200-mesh screen in order to obtain a satisfactory extraction. According to laboratory experiments by J. M. Callow and E. B. Thornhill\* this fine native silver floats more readily than any other silver-bearing mineral. Actual full-scale work in the mills, however, fails to support this statement.

**EARLY MILLING.** The first mills erected at Cobalt were equipped with crushers, stamps or rolls, jigs, and gravity tables, two products being obtained, a concentrate assaying several thousand ounces per ton, that was

sold to the smelters, and a tailing that was stored and is now the principal material available for treatment by the flotation process. Later plants were equipped for both gravity concentration and treatment by cyanide. At this date (October, 1917), owing to the success achieved by the Buffalo Mines, every mill is either equipped with a flotation annex or has one under consideration.

**APPLICABILITY OF FLOTATION.** In reaching a decision regarding the adoption of a process and the installation of a plant, two factors exert an influence in favor of

FIG. 1. THE GROCH IMPELLER

flotation at Cobalt more than in mining districts generally; these are (1) the winter is long and heating is costly, and (2) many of the mines appear to have already passed the zenith of their prosperity, their ore-reserves being now narrowly limited in extent. The most desirable process for the Cobalt mines, therefore, is one that can be housed in the smallest building and installed with the lowest capital outlay. Experience has proved that a flotation plant can be erected in a space less than one-fourth that required for either a group of gravity-tables or a cyanide-plant of equal capacity. In a modern mill for treating 100 tons per day it is estimated that a saving in capital expenditure of about \$20,000 can be effected by the substitution of the new for either of the older methods. The working profit also favors the newer method. The chief handicap to flotation is its inability to produce a finished article, that is, one easily marketable, such as high-grade bullion. Flotation in reality is a method for concentrating valuable mineral into small bulk, the ratio of the weight of material treated to that of the product being, in the Cobalt district, approximately between 50 and 100 to 1. This concentrate either must be treated locally or sold to distant smelters, whereas if cyanide bullion is produced no further treatment is necessary.

\*Bull. Can. Min. Inst., June 1917.

**FLOTATION-OILS.** Owing to the difficulty in floating the arsenides and other refractory minerals with which the silver is associated, the oil-mixture to be used must fulfil the conditions of being a collector, a frother, and a powerful adhesive. The Cobalt blend of oil consists of 20% pine oil, 70% creosote, and 10% tar. The last does not have the selective action on the valuable minerals that could be desired, its function being to adhere tenaciously to the mineral and improve the recovery, although this is at the expense of the grade of the concentrate produced. The consumption of oil through-

slotted or submerged so as to compel the pulp to take a zigzag course, both vertically and horizontally, in its passage through the machine. The impellers, six in number, combine the functions of centrifugally agitating the pulp, diffusing the oil, and sucking air into the mass during agitation, all accomplished in one operation. The impeller consists of a hollow vertical shaft to which is attached at the lower end a duplex centrifugal 'runner,' similar in design to a pair of centrifugal pumps separated from each other by a disc. During the operation this is submerged in the pulp. The discharge from

FIG. 2. THE GROCH FLOTATION MACHINE

FIG. 3. THE GROCH IMPELLER

FIG. 4. THE RUTH IMPELLER

out the district varies from  $\frac{1}{2}$  lb. to 2 lb. per ton of material treated.

**FLOTATION APPLIANCES.** The Callow system of flotation was the first to operate commercially in the district, and, as the results obtained were satisfactory, the pneumatic cell rapidly became popular. The Callow appliance has been so often described that a repetition here is unnecessary. Recently a machine, the invention of a local engineer, F. O. Groch, has made its appearance, and indications are that it possesses merits that should entitle it to consideration. Externally it bears a striking resemblance to the Minerals Separation machine, but the method of operating is quite different. It may be described as a number of impellers operating in a V-box 14 ft. long by 5 ft. wide, divided transversely and longitudinally into compartments, the partitions being

the 'runner' is at the periphery and the pulp-intake to the lower part is from below through the hollow hub, while the upper part has its inlet for oil and air through the hollow shaft. In operation the pulp is admitted into the first compartment at the bottom of the V-box on the under side of a false bottom through which the hollow hub of the centrifugal 'runner' protrudes. There it is transferred from the lower to the upper side of the false bottom by being sucked up through the hollow hub, to be subsequently discharged in a horizontal plane at the periphery. This violent ejection creates a vacuum that reacts in such manner as to suck into the vortex everything in its neighborhood, including the contents of the upper part of the 'runner.' As this upper part has its inlet from the top of the hollow shaft the result is that a lavish supply of air is drawn

into the impeller and discharged into the pulp in the form of an infinite number of minute bubbles. Theoretically this is precisely what is required for ideal flotation. A working model of the Groch machine was recently shown at the National Exhibition of Chemical Industries, New York, and the discovery was then made that, as so often happens, another operator, Joseph P. Ruth, of Denver, had independently hit upon practically the same idea and was gaining considerable success in the West with his improvement. Illustrations of the impellers of both Mr. Ruth and Mr. Groch are here shown for purposes of comparison. See Fig. 1, 2, and 3.

In the Groch machine, the oil is admitted, drop by drop, through the hollow shaft of each impeller, where it falls on the rapidly revolving disc, and is, as it were, atomized and shot into the pulp along with the minute air-bubbles. By feeding different oils into the pulp through the impellers in series so that the minerals in an ore are brought into contact with oils of increasing viscosity it is claimed that preferential selection is obtainable. The idea is worthy of further investigation, and it is possible that a decided improvement can be obtained over existing methods.

THE CHEMICAL COMPOSITION of the concentrate recovered by flotation differs greatly from that obtained by the gravity method of treatment on tables, for the reason that the physical properties, specific gravity, and flotability of minerals bear no relation to each other. Arsenides, with which the silver is invariably associated, are difficult to float, while chalcopyrite, a frequent constituent of the ore, floats readily. Comparative analyses follow:

	Gravity concentrate	Flotation concentrate
Silver .....	1000-2000 oz. per ton	300-500 oz. per ton
	%	%
Copper .....	0.3	1.0
Arsenic .....	25-40.0	0.5
Nickel .....	3-6.0	0.25
Cobalt .....	5-7.5	0.25
Iron .....	10.0	9.0
Sulphur .....	5.5	3.0
Alumina .....	7.0	18.0
Lime .....	5.5	6.5
Silica .....	15.0	55.0

This difference in composition was not anticipated at the time when the introduction of the flotation process was first taken under consideration, so that the situation developed in an unexpected manner. Several smelting companies that had been particularly keen to purchase the gravity concentrate absolutely refused to tender for the flotation product. Its extreme fineness and its deficiency in nickel, cobalt, and arsenic, from which at present valuable by-products are being obtained, is doubtless the cause of its unpopularity.

MARKETING THE CONCENTRATE. The greatest drawback to the flotation process, so far as Cobalt is concerned, has been the high cost of shipping and treating the product. The American Smelting & Refining Co. is practically the only purchaser able to accept any large

quantity of the material. This buyer has fixed an arbitrary charge for treatment, and makes payment on 95% of the assay-value, which results in a total cost to the mining companies of approximately \$40 to \$50 per ton of concentrate exported. Assuming a concentrate assaying 500 oz., with silver at 70c. per oz., based on shipment from Cobalt to Denver, the details of cost are as follows:

	Per ton of concentrate
Steam-drying to approximately 10% moisture, coal at \$7.50 per ton.....	\$2.50
Sacking and loading .....	1.35
Sacks and wire-ties (allowing five trips per sack; original cost of sack, 15c.).....	1.05
Haulage from plant to cars at Cobalt, about.....	0.75
Freight, Cobalt to Denver.....	14.20
Treatment-charge at smelter.....	10.00
Extraction-loss, 5% on 500 oz. silver at 70%.....	17.50
Incidentals:	
U. S. revenue, per car.....	\$1.20
Assaying .....	6.00
Customs' charge .....	2.50
Representative at sampling.....	7.00
Total .....	\$16.70
Total .....	\$47.77

LOCAL TREATMENT OF CONCENTRATE. Two methods of treatment locally are being tried, the one necessitating roasting of the concentrate, the other operating with this material in its raw state. The roasting process consists in placing the concentrate, with 15% moisture, in a specially constructed furnace, patented by the Holt-Dern organization, where it is slowly oxidized without allowing any flame to reach the surface. The charge is a mixture of gravity and flotation-concentrate in the ratio of 1:4, giving a self-roasting mixture, the fuel being supplied from the sulphur, antimony, and arsenic present. The furnace may be described as a 7 by 9 ft. rectangular brick-lined chamber 4½ ft. deep, into which during operation the charge is fed wet at regular intervals, a corresponding amount of the roasted product being simultaneously withdrawn underneath through the patented grate with which the furnace is equipped. Thus a blanket of wet concentrate remains continuously on top, minimizing the loss by dusting and volatilization. The contained moisture is really a saturated solution of common salt from which the chloridizing effect is derived.

The roasted material is leached with brine and the silver precipitated on scrap-copper. The copper is later recovered by precipitation on scrap-iron. The resulting silver, in the form of a cement, is treated with acid and melted.

The cost of this treatment is not yet ascertainable as many difficulties are being experienced that will require ingenuity to overcome. The brine eventually becomes foul and the customary high-grade bullion, which Cobalt operators consider as their standard for export, is not obtainable except at a prohibitive cost for labor and acid.

Leaching by brine may be replaced later by agitation

in cyanide solution, thereby eliminating some of the difficulties, but at an increased cost. For this work a thorough roast would be essential and this is scarcely obtainable in any furnace where the charge remains motionless during the whole operation. Results so far indicate that the charge has a tendency to sinter. There remains the alternative of dealing with the concentrate in its unroasted state. Here, as in so many other matters, local metallurgists have shown remarkable enterprise, and hopes are entertained that a process, already installed at the Cobalt Reduction Works for the treatment of gravity concentrate, may prove applicable to the flotation product. This process consists of intensive tube-milling, first in water with 25 lb. of calcium hypochlorite per ton of concentrate treated. The operation exerts an oxidizing and chloridizing effect, which is completed in about 24 hours. Then follows a period of water-washing and agitation in a 0.25% cyanide solution for 48 hours, during which time about 95% of the silver-content is extracted. Filtering then follows, and precipitation from the solution is effected by the sodium-sulphide method with the production of bullion 996 fine.

This method applied to flotation-concentrate has so far failed badly. The oil-mixture used for the recovery of the concentrate is of a decidedly tarry and adhesive character; consequently the difficulty of attacking the oil-enveloped particles with the cyanide is even greater than that experienced generally in dealing with flotation concentrate. A vigorous campaign of experimental research is being started and it is confidently expected that the existing difficulties will be overcome.

**RECOVERY AND COST OF OPERATION.** The litigation, with which the Cobalt district is being threatened, prohibits the publication of authoritative details for fear that they may be used subsequently in law-court proceedings. It may be stated, however, that, as a general rule, the recovery varies from 75 to 90% of the silver in the material treated by flotation and the cost of the actual operations from the time of receiving the slimed feed to that of discharging the finished concentrate is roughly 20c. per ton, divided as follows:

Item	Cents
Oil .....	4
Labor .....	9
Power .....	6
Repairs .....	1
	—
	20

The estimated cost of treating the accumulated sand-tailing of the Buffalo Mines by flotation, and of converting the concentrate recovered into actual cash, is given in detail by Robert E. Dye in a paper read before the Canadian Mining Institute in March 1917, together with those obtained in previous operations by sliming in cyanide. The particulars are as follows:

	Flotation cents	Cyanidation cents
Loading tailing by steam-shovel.....	4	4
Tube-milling and classifying.....	40	50

	Flotation cents	Cyanidation cents
Heating and lighting.....	3	10
Overhead expense .....	14	14
Thickening, agitating, etc.....	..	16
Chemicals .....	..	48
Precipitation and miscellanies.....	..	17
Refining .....	..	3
Flotation .....	8	..
Drying and loading concentrate.....	5	..
	74	\$1.62
Smelter-charge, including freight and losses .....	83	..
Total, per ton.....	\$1.57	\$1.62

A 90% recovery is obtained by flotation, and a similar extraction by cyanidation to which intensive tube-milling is a contributing factor. The working cost for both systems is practically identical, but there are possibilities of reduction in the cost of treating flotation concentrate that do not exist in the competitive method. No charge is shown in the foregoing figures for amortization and depreciation, and as the quantity of material available for treatment at the Buffalo Mines is not over 350,000 tons, the deciding factor of capital expenditure is overwhelmingly in favor of flotation. A promising avenue for research in Cobalt is being found in the endeavor to obtain a combination treatment of sliming in cyanide followed by flotation. It has been discovered that, if the customary strong cyanide solution be used, subsequent treatment by flotation is abortive, and that the flotation recovery is increased as the cyanide solution used in the initial treatment is weakened. The probable reason for this is that strong cyanide, in attacking the silver-bearing minerals, pits their surface, thereby lowering their flotability. Experiment shows that a reduction in the strength of the usual working solution from 0.25% NaCN to 0.10% lowers the extraction by that chemical from the regular 90% to 75% of the silver in the ore, but it leaves the residue in such a state that, with suitable water-washing, a further 75% of the content is readily recoverable by flotation. This modification is showing a saving of over one-third of the cyanide ordinarily consumed.

**MINERALS SEPARATION.** In harmony with its attitude elsewhere, the Minerals Separation company, through its subsidiary organization, the North American Corporation, has threatened proceedings against all users of flotation in the Cobalt district, so as to collect, if possible, the royalty of 2½% of the gross value of the whole concentrate recovered, according to the usual demands of this patent-exploiting company. The success of flotation at Cobalt is due entirely to local enterprise, therefore this demand is resented bitterly. The indications are that a legal fight is to follow, and a campaign has been started to enlist Government action "with a view to having the patents annulled." Amid the legal turmoil, metallurgical progress is being seriously handicapped, the free exchange of ideas has been completely stopped, and an embargo is being placed on valuable information.

It is sincerely hoped that an equitable settlement may be obtained at the earliest possible moment.

**CONCLUSION.** Flotation is undoubtedly destined to play a part in all milling operations in the Cobalt district, although its scope will not be as extensive as was at first anticipated. As a competitor to the sand-table it has not met with the success gained in other localities for the reason that the valuable minerals are difficult to float and are easily recoverable by gravity-methods. For successful flotation, the arsenic, nickel, and cobalt minerals, with which much of the silver is associated, must be reduced to a fine state of subdivision in order to conform to some flotation law in which the ratio of surface-area to mass is an important factor. Fine crushing is expensive; consequently the best field for flotation lies in the treatment of primary slime. On this material, it has already completely superseded the slime-table, the additional revenue being greatly in excess of any additional cost incurred. One concentrating plant treating 150 tons of ore per day has been able to add to its recovery from 200 to 300 oz. of silver in concentrate daily, the additional revenue being directly attributable to the introduction of flotation for the treatment of slime. The approved type of gravity mill for Cobalt, therefore, should contain jigs for the extraction of the coarse metallic silver, gravity tables for the treatment of sand, and flotation for the slime.

In the cyanidation of Cobalt ore, certain inroads by flotation have been made, but this results not so much from the actual benefits derived from the use of flotation as from the disadvantages both temporary and permanent associated with the older system. During the War, a shortage of cyanide has been frequently threatened and the finding of some substitute has become imperative. No actual shortage in Canada has, so far, been experienced but the possibility of having to suspend operations for this reason has acted as an incentive to the development of flotation.

Cyanidation lacks elasticity, especially in respect of the cost-sheet. A fixed consumption of cyanide per ton of ore treated has to be incurred regardless of the value of the material being cyanided. This means practically a fixed limit of cost with no margin for fluctuations in revenue. The ores of Cobalt are notoriously erratic in value, consequently, on many mines, often owing to a fall in grade, cyanidation is actually being conducted at a loss. With flotation, the chief item of cost is directly associated with the treatment of the valuable concentrate produced, consequently the total cost of the whole operation fluctuates directly as the value of the ore being treated. This is a most favorable factor. A combined cyaniding and flotation plant should therefore give an improved recovery, effect a saving in cyanide, and automatically harmonize the cost of treatment with the value of the ore being milled.

Flotation has already been allotted a useful place on practically every producing mine in the district and its sphere of operation is bound to increase greatly as soon as a more advantageous method of disposing of the

product has been devised. The probabilities in this matter seem to favor treatment locally.

The capital outlay for a flotation annex, with storage-tanks, filter, buildings, etc., but no crushing appliances, is roughly \$50 to \$60 per ton of daily capacity. This, in itself, gives the process an advantage over all competitors.

The flotation of silver ores is now a well-established success and the results being obtained from researches in the Cobalt district should prove of much interest to operators in other countries particularly Old Mexico, where the argentiferous minerals are less refractory and can be much more readily treated than those of New Ontario.

## Road-Building Over Wet Soft Ground

Wagon-roads built to reach mines in the mountains are frequently impassable in places on account of the existence of wet areas that constitute weak links in the chain of connection between the mine and the shipping-point at the railroad. To overcome these bad spots, a method that has been thoroughly tested by the U. S. Government may be applied; this is known as the burned clay method. The roadbed is plowed as deeply as possible. Furrows are then dug across from ditch to ditch, extending through and beyond the width to be burned. For a 12-ft. roadway the transverse furrow should be 16 ft. long, extending 2 ft. on each side. Across the ridges between the furrows, which should be about 4 ft. apart, a course of cord-wood is laid longitudinally to form a series of flues. These should be laid so that the pieces will touch, forming a floor. Another layer of wood is thrown irregularly across this floor in crib-formation, with spaces left between, in which clay is piled. The lumps of clay placed on the crib-floor should be coarse enough to permit a draught for easy combustion. A third course of wood is laid, in the same manner as the first, on top of this, and each opening and crack is filled with brush, chips, bark, small sticks, or other combustible material. A top layer of clay is placed over all this, being the material dug from the side ditches. The top layer should be from 6 to 12 in. thick. The best results are obtained by firing all the flues of a section simultaneously, and maintaining combustion as evenly as possible. A supply of light dry kindling should be at hand to prevent the fire from dying down at any one place. The firing should be started on the windward side. If the combustion is too rapid, it may be checked by banking the mouth of the flue with clay. When sufficiently cool the roadbed should be brought to a high crown before rolling, in order to allow for compacting of the material. The finished crown should have a slope toward the sides of about  $\frac{1}{2}$  in. to the foot. The cost is estimated at approximately \$85 for each 300 ft. A road treated in this way will not become plastic when wet; it will remain hard, and will carry heavy loads. Clay clinker burned in this way is used on many railroads for ballast, particularly in Illinois, Indiana, and in some of the Southern States.

THE YOSEMITE DREDGE, AT SNELLING, CALIFORNIA

## Recovery of Platinum in Gold-Dredging

BY JAMES W. NEILL

By JAMES W. NEILL

During the 22½ months preceding July 1, 1917, the Yosemite Dredging & Mining Co.'s 3¼-ft. dredge, operating on the Merced river, near Snelling, California, shipped to market a concentrated 'black sand' from the clean-ups for the following returns:

Months	Yards	Black sand, Platinum.		Value	Per yard	Receipts, total	Per yard
		lb.	dwt.				
9	617,500	921	365.25	\$1734.95	0.281	\$1913.10	0.310
4.5	308,750	622	172.25	732.05	0.237	795.30	0.260
9	617,500	1011	285.75	971.55	0.157	1078.05	0.177
22.5	1,534,750	2554	823.25	\$3438.25	0.222	\$3786.45	0.248

In addition to the platinum, there was recovered 18.75 dwt. osmiridium valued at \$24.75 total, and 369 dwt. gold worth \$369. This indicates a value per pound of sand shipped of \$1.48. Prices of platinum received were \$3.40, \$4.25, and \$4.75 per dwt., the highest figure covering the latest shipment. The refiners, Shreve & Co. of San Francisco, state that this product carries a higher proportion of platinum to osmiridium than any received from mines in the State, other shipments carrying as high as 50% of osmiridium.

If the 65 million yards of gravel dug annually by

dredges in the State of California all yielded platinum in this same proportion, namely 0.25c. per yard, it would amount to \$150,000 per annum. I am informed that there is some platinum in all the gravel mined, the amount varying with locality, but also more probably, with the methods used to save the metal. On our Yosemite dredge the following method is used to produce the sand described in the table above. The dredge uses Hungarian riffles of 1 by ¾-in. angle-iron, set one inch apart. At clean-up time these are removed, the gravel loosened, and shoveled to the top end of the table, or sluice, then streamed down with water from a hose, stirring meanwhile with rake, or hand, to get rid of the pebbles and lighter sand. After this operation there remains on each table a small pile of sand and amalgam, which is scooped into an enameled bucket and dumped into the long-tom box, usually at the rate of one small bucket to each table.

This long-tom is of wood, 5 ft. long by 2 ft. wide and deep, set at an angle of 1½ in. per foot. At its lower end a slot delivers the pulp into a bucket set in the upper end of a sluice-box, to catch the amalgam and quick-

THE LONG-TOM AND SLUICES FOR GOLD-SAVING

silver. The overflow from this bucket drops upon the sluice, whence it passes over a shallow quicksilver trap, and then over five feet of riffles set in the sluice; thence the material flows to waste overboard. The sluice below the quicksilver traps is 10 in. wide by 6 in. deep, therefore the capacity of the riffles is small.

All the material from the clean-up is handled in this way, and everything from the long-tom passes over these riffles. When all has been worked up, the riffles in this sluice are lifted, placed in the long-tom box, and washed down again, to remove as much quicksilver as possible, but this time the launder is left without riffles, and all the sand is washed into a galvanized-iron tub, passing on the way through a 20-mesh screen held under the spout by one of the operators.

The coarse material saved in this way is picked over by hand, usually yielding a few small nuggets, half quartz and half gold, the rest being chips of iron, lead, shot, etc., all of which goes back onto the tables. This sand, so produced, is stored, dried, sacked, and finally shipped, yielding as shown in the table given above.

It might naturally be supposed that with the rather crude methods described there will be some loss of platinum and no doubt there is, but I have panned the tailing flowing from this sluice many times, with either entirely negative or very low results; hence I am led to believe that the losses are negligible. Nevertheless, another 5-ft. length has been added to this launder, thus doubling the riffle-area.

Whereas the specific gravities of gold and platinum are practically the same, as also are the particles in size and shape, the conditions governing the recovery of the metals on the dredge are entirely different. The particles of gold are covered by the quicksilver and soon become agglomerated into lumps that are covered by the little pools of 'quick' gathered in the riffles, pockets, and stops, or adhering to the metallic surface in less exposed places. The platinum, not having any affinity for quicksilver under ordinary conditions, is dependent solely on its gravity to keep it in the riffles (like, of course, the coated or rusty gold); hence there must be a considerable loss of very fine or very light grains of platinum. Those familiar with dredging know well that the spaces between the riffles, supposed to form pockets in which there may be some 'riffing' action or some space for metals to settle, quickly become filled with pebbles, the interstices between these being filled with sand and the whole then thoroughly cemented with mud, until it is not possible to make a dent in the surface with a finger or thumb. It seems a miracle that any metal is retained under such conditions! Ordinarily such a surface is all that is offered to the platinum for a resting place.

The Yosemite dredge is equipped with ten Neill jigs, one set at the lower end of each of the first four tables on each side, the other two being set near the distributor, in the sixth table, and handling sand from both the fifth and sixth tables in order to get the necessary fall. These jigs are of the smallest size, having a screen-area of only two feet along the travel of the gravel; they are fitted

with an 8-mesh screen and use one to two inches of cast-iron shot-bedding, and deliver a hutch concentrate all 20-mesh or finer. This jig-product is passed over stationary silvered copper plates of varying length, placed in launders below the regular tables, from five to only two feet, according to the space and fall available. All deliver the pulp into one straight sluice which empties over the stern. This latter has a fall of only half an inch per foot, which is too flat, but that is all the fall available. The upper portion of this sluice has a flat bottom, without riffles, but the last five or six feet has riffles, consisting of inch-boards through which one and one-half inch holes have been bored spaced at 5-ft. intervals.

This apparatus yields \$200 to \$500 per month in amalgam from the plates, and a considerable amount of quicksilver from the riffles below the plates. These riffles were only lifted and the material washed down in the long-tom twice per month at clean-up times. This arrangement of the plates, and riffles to handle the jig-concentrate, is not that originally designed for the dredge, as was illustrated in my article\* in a previous issue of this paper (November 28, 1914). That called for elevating all the concentrate to the upper floor, settling in spitzkasten, flow over 3 by 8-ft. plates one on each side of boat, long launders below the plates in which by riffles and stops to detain the platinum and mercury, or, if found necessary, there was sufficient fall for the placing of a Wilfley table. This equipment was not re-installed when the boat was re-fitted, the present arrangement allowing us to dispose of the two sand-pumps and the costs of a man per shift to watch the apparatus; in other words, the later equipment is the application of commercial metallurgy as against theoretical metallurgy.

In order to determine the amount of sand-concentrate produced by these jigs, and its possible value, I took an ordinary galvanized-iron tub holding 17 gal. of water, arranged a movable spout for the end of the plate-tailing launder, and then proceeded to take samples of the tailing, timing the flow until the tub was full, then allowing a short time for the sand to settle, pouring off the water and slime, and weighing the sand. This sampling was continued during several days at intervals of 15 minutes, first on one side of the dredge, then on the other. In this way one complete cut across the pond was sampled, the product weighed, the amount of water measured, and a sample obtained for assay. The tabulated result indicated a flow of 100 gal. water per minute from all 10 jigs, and 42,000 lb. of wet sand in a 22-hour day, or 35,037 lb. dry weight. The sample was sent to the General Engineering Co. of Salt Lake City, and by them run over a laboratory Wilfley table returning to me the concentrate. This test resulted as follows:

	%
Concentrate .....	1.81
Middling .....	7.25
Tailing .....	90.94
	<hr/> 100.00

\*See also 'Gold-Saving on Dredges,' by Howard D. Smith. M. & S. P., August 5, 1916.

The concentrate was sent to Shreve & Co., who refined it for me, and reported half an ounce of platinum metals per ton.

This, therefore, would indicate

$$35031 \times 1.81 = 634 \text{ lb. concentrate per day}$$

$$634 \times 30 = 19020 \text{ lb. per month}$$

$$\frac{2000}{19020} = 9.5 \text{ tons at } 0.5 \text{ oz. platinum or } 4.75 \text{ oz. at, say, } \$90 \text{ per ounce.}$$

Thus an apparent loss of \$427 per month is shown, against a total caught and saved in the riffles of about \$150 per month.

Naturally, it would not be fair to expect exactly such results each and every month, as the yield of platinum metals would be nearly proportionate to that of gold. The month during which this test was made being about a normal month in dredge-yield, one might reasonably look for an average as indicated.

Following this test, I had several tests made on the material remaining on the riffles in the launders below the plates, and in every case these have proved of considerable value, in one case 600 lb. of the sand yielded 100 lb. of concentrate carrying 6c. per pound in platinum and gold, in the ratio of 4.5:1.

The next question was how to handle the material, and would a Wilfley table work on the dredge during the operating time? The consensus of expert opinion was that it would not, but, in spite of this I purchased a half-size Wilfley and set it up on the upper deck of the dredge. This table has a standard timber frame but its deck is half the normal size, the total weight being about 2100 lb. The upper deck in our dredge is of light wooden construction, sloped rather sharply to the sides, so we placed upon the floor two 4 by 8 in. timbers, 12 ft. long, set them level fore and aft and cross-ship, and bolted the table-frame to this, placing no underpinning or supports below. The motor was set on one of these 4 x 8's and was belted to a 20-in. pulley, which gave us the required speed, 325 revolutions per minute. The water supply comes from the priming pump, delivered into a 50-gal. barrel, and thence by  $\frac{3}{4}$ -in. pipe to the feed and wash-water troughs on the table.

The sand from the jigs is elevated by a Krogh sand-pump into a V-bottom tank 4 ft. square with peripheral overflow, the flow of the sand to the table being regulated by means of molasses cocks, and the overflow water going to the wash-water barrel.

Contrary to expectation, the table, under normal conditions of digging, runs perfectly. Raising or lowering the digging-ladder changes the table-level and interferes with the discharge of the concentrate, but this is readily remedied by a wedge under the tail end of the table-frame, and as the ladder is not often moved this creates no difficulty.

The frequent and often rather violent surging of our little boat, which digs into pretty stiff ground and bed-rock at times, does not interfere with the operation at all; waves of water and some light sand pass lengthwise of the table, but the streak of concentrate once formed

clings to the surface and holds its line in spite of these surges. One may cut a greater or lesser streak of concentrate as desired, and this will preserve itself without change of table-inclination or of cutting-launders for an hour, or hours at a time. Naturally, in this case one does not look for the precision in concentration desired in copper or lead-mining work; nor is it necessary. The streak of concentrate shows at its upper edge a fine white line of minute globules of floured quicksilver, and with this, or detained by some black sand just along side of it, the particles of gold and platinum, which are practically all contained in the upper few inches of the concentrate streak. The free quicksilver in large globules travels along the ends of the table-riffles and finally lands in the middling-compartment, some of it, probably 'lazy' from contained gold, goes into the concentrate-compartment.

Preliminary work with the table demonstrated the necessity for an efficient quicksilver-trap on the feed end of the table, so as to get rid of this element in the concentrate, and relieve the operator of the need of close watching to prevent its loss. Also we found it necessary to install a screen to take out some oversize pebbles, and such shot as gets through broken screens.

## Zinc From Low-Grade Complex Ores

During the past two years many processes for the treatment of the oxidized ores of zinc have been investigated at the Salt Lake City station of the Bureau of Mines. In the treatment of most ores the proposed hydro-metallurgical processes have been found to present serious difficulties. On the other hand, zinc-sulphide ores are at present being treated by such processes with considerable success. Owing to the difficulties in attempting to apply hydro-metallurgical processes to oxidized ores of zinc, an igneous concentration process was tested, with encouraging results. The process consists in blowing a blast of air through a mixture of oxidized zinc ore, coke, and limestone. As a result the zinc oxide was drawn off as a fume, which could have been collected in a bag-house, or by electro-static precipitation. The ore from which the zinc has been volatilized forms a slag in the furnace, and is tapped off in the usual manner. The commercial application of such a process is important, as at present there is no process being used that permits the successful concentration of low-grade oxidized ores of zinc. Such ores have been accumulating in all of the important mining districts of the United States, especially in Utah, where there are large deposits.

METALLIC MAGNESIUM is now worth about \$4 per pound. This price is the great deterrent to its use in the alloy with aluminum, known as magnalium, which was previously described in the MINING AND SCIENTIFIC PRESS. Electro-chemists are urged by the Council of National Defense to endeavor to solve the problem of producing it cheaply.

## Blasting Troubles

Blasting-practice offers many chances for exasperating errors that result in loss of time, labor, and supplies, even if no more serious consequences follow. Every little while an epidemic of some special difficulty will break out, and the foreman may have a long hunt to ascertain the cause. At one mine in Mexico persistent trouble was experienced with 'stinkers' and misfires. The investigation was finally extended to the magazine, which was a low frame structure built into the hillside and covered with dirt. It was summer-time, and the atmosphere was hot and moist; the magazine was poorly ventilated, and the manager had put in store a large supply of 40% dynamite, sufficient for the operation of the mine for a year. The boxes of powder had never been turned while in the magazine, and the high temperature had promoted drainage of the nitroglycerine toward the lower side of the cartridge. Nitroglycerine had leaked out; the boxes were saturated with it; and the homogeneity of the explosive had been destroyed.

Deterioration of explosive through moisture when old damp tunnels are used for storage is well-known. The objection is not to the tunnel but to the moisture. Even at moderate temperatures the moisture facilitates the seepage of the sodium nitrate from the 'dope.' This salt is mixed with the cellulose, or other absorbent, in order to furnish oxygen for its combustion, thus removing what otherwise would be a cause of retardation of the velocity of the detonating wave. It is a very deliquescent salt, much more so than potassium nitrate, which is too expensive to be employed for this purpose. In consequence of the readiness of the nitrate to absorb moisture from the air, it exudes from the cartridge and forms saline crusts on the wrapper and on the box. As soon as it has begun to exude the homogeneity of the powder is gone; the nitroglycerine will then more quickly drain from the dope; the deterioration of the powder will be impaired, and 'stinkers,' misfires, and low-energy explosions result. It is cheaper to provide a dry storage-place than to use a ready-made magazine that is damp. If a man does not choose to determine the moisture in some of the simple ways that every chemist knows, he is, at least, likely to possess a cultivated sense of discrimination between a damp and a dry cigar; let him leave a cigar in the place proposed to be used as a magazine, and in 24 hours he will know what to do, for a place that proves to be a good humidor for cigars is too damp for the economical storage of powder.

Another fertile cause of trouble arises from the improper handling of fuse. At a mine in New Mexico an experienced foreman, sinking a shaft on contract, was in despair over what he called "a perfect spree of misfires." He should have made an advance of three feet per day, but he was gaining only six inches instead. He called on a well-known mining engineer for advice.

The fuse was inspected, a few lengths burned, a few caps exploded, and the dynamite carefully investigated. The engineer then asked to have the day's primers made up; he watched the miner cut a few lengths of fuse for which purpose the ordinary combined crimper and fuse-cutter was used. The engineer asked to see the tool, and found that the blades were dull and the joints loose. The result was that the instrument pinched the fuse while cutting it, thus crowding the powder-stream and leaving a thick ridge of the asphaltic paste where the powder should spit into the fulminate. Side-spitting was the result, so that only an occasional fuse would set off the cap. That day he cut the fuse square across with a sharp knife, and there was not a single mis-fire in the round of shots.

## The Rusting of Iron

When we consider the enormous economic waste due to the corrosion of iron, a waste which the Bureau of Mines estimates to be in the neighborhood of 1,000,000 tons of that metal per year, to say nothing of the amount of zinc, other protective metals, and paint annually applied in an effort to diminish this waste, there is abundant reason why time and money should be spent in a thorough study of the problem. The Bureau rejects the electrolytic theory that has been so universally accepted, on the ground that pure iron, that is to say, the purest iron obtainable, rusts and pits as badly and often worse, than the impure product. The work of the Bureau during the last year has been devoted to the study of surface influences, particularly to the influence of rust once formed on the progress of further rusting. The investigation has shown that rust is a factor in the progress of rusting; that there is a reverse polarity according as the rust is dry or wet; that the iron underlying freshly-formed rust is electro-positive to the surrounding metal, and consequently goes into solution; and that dried rust assumes a negative polarity which tends to reverse if it becomes thoroughly wetted. What is considered to be a most important finding is that wet rust does not act as an electrode but as a semi-permeable diaphragm that makes the underlying iron electro-positive, and this promotes its solution. These findings would seem to support rather than to reject the electrolytic theory. That rust begets rust was accepted, if we remember rightly, by John Percy, but he accounts for it as a chemical rather than a physical process. He considered the rust to be a continual conveyer of oxygen from the atmosphere on the one side to the iron on the other; thus, on the outside, the reaction

was taking place, while on the inside the reaction would be expressed by

That both chemical and electrical reactions take place in the rusting of iron is beyond doubt, but which is cause and which is effect is not yet proved.

# American Smelting v. Bunker Hill

AFFIDAVIT BY F. W. BRADLEY

F. W. BRADLEY, being first duly sworn, on oath says:

I was educated as a mining engineer and have been continuously engaged in the business of mining for the last 34 years. My first connection with defendant was in 1890 as assistant-manager, when construction was beginning on the first of its present concentrating plants. I served in that capacity at Wardner, Idaho, until 1892, when I was made manager. I then served defendant as manager at Kellogg, Idaho, until 1897 when I was made president, and have served ever since in that capacity from offices at San Francisco.

In 1898 I became a director in the Tacoma Smelting Company; and in 1900 was made president of that company, in which capacity I served until June, 1905, when I resigned on learning that the Federal Mining & Smelting Co. (under the same control as the Tacoma Smelting Co.) had begun an extralateral-right suit against the defendant. In 1900 I was appointed consulting engineer for the Alaska Treadwell, Alaska Mexican, and Alaska United gold-mining companies. I served these companies in that capacity until 1911, when I was made their president, in which capacity I am still serving these Alaska companies. Before the year 1890 I was and ever since have been actively engaged in mining at many other places and with many other companies.

The building up of defendant's property has been a long slow process. Because of disappointments in ore-values at the beginning, the work could only be carried along as the mine earned sufficient profit to pay for it; besides the policy of keeping the development work well in advance of ore-shipments finally exposed sufficient ore to excite the cupidity of neighbors, which resulted in a vast amount of extralateral-right litigation. Ore had to be found and put in sight from time to time, so that the proper and necessary equipment of the property could be planned and provided for.

The ore in defendant's mine has been made payable under past conditions by the mineral galena carrying from one-third to one-half of an ounce silver to each per cent of lead. When pure, galena consists of 86.6% lead and 13.4% silver. In addition to gold and silver, some galena in the Bunker Hill & Sullivan mine carries such other impurities as salts of zinc, copper, antimony, bismuth, etc. The country-rock of the Wardner district is composed of layers of quartzite, shale, etc. The galena occurs irregularly scattered in the shape of stringers and bunches in veins that traverse the country-rock. These veins in turn have been broken up, dislocated, thrown, and twisted by many faults, the Wardner district being one of the most excessively faulted areas of similar extent in the world. The galena is often

disseminated throughout the vein-matter, which in many cases consists of masses of iron carbonate, and it is also at times found disseminated in the country-rock itself. In either of these cases of dissemination, it is both wasteful and unprofitable to concentrate such ores under methods of concentration heretofore in use because of the severe tailing-losses.

The disappointment at the beginning, referred to above, was that it required a greater number of tons of ore from the mine to produce one ton of a product rich enough to ship at a profit than originally figured on. That is, as ore was found, it did not average as much per ton in lead and silver as originally expected. There never has been from the beginning any concern as to the sale and marketing of ore. In my time with the Tacoma smelter, it was always possible to make contracts for the sale of lead and silver; and we have found it possible to make sales of the lead and silver products of our new smelter at Kellogg. The primary and great concern was to find ore in payable quantities and then to protect the ore so found from predatory litigation. After finding and securing payable orebodies, the next problem has always been the concentration of the ore into sufficiently clean shape from the barren vein-gangue and country-rock to pay for freighting the cleaned or concentrated product to distant custom lead-smelters, which always stood ready, until June, 1915, to buy the ore when and as prepared for shipment.

In those years of smelter competition, representatives of the different smelting companies made it a practice of calling at the Bunker Hill & Sullivan office, at Kellogg, Idaho, for the purpose of soliciting shipment of ore to their many plants at varying freight and treatment rates, depending upon the quantity of silicious ores being shipped to them, refining-rates, freight-rates, etc. This followed the original practice of auctioning the ore for sale to the highest bidder, and resulted in the making of many concurrent and over-lapping contracts for any quantity of ore that we had to spare and for periods of time varying from six months to one or five years; and in practically all cases provided that the Bunker Hill company would have the benefit of any reduction in freight-rates, and also be paid for any excess in iron. Such smelting companies were the Globe Smelting & Refining Co., operating at Denver, Colorado; the Pennsylvania Smelting Co., operating at Carnegie, Pennsylvania; the Ohio & Colorado Smelting & Refining Co., operating at Salida, Colorado; the Selby Smelting & Lead Co., operating at Selby, California; the Puget Sound Reduction Co., operating at Everett, Washington; the Philadelphia Smelting & Refining Co., operating at

Pueblo, Colorado; the Colorado Smelting & Refining Co., operating in Colorado; the Tacoma Smelting Co., operating at Tacoma, Washington; the United Smelting & Refining Co., operating at East Helena, Montana; the Pueblo Smelting & Refining Co., operating at Pueblo, Colorado; the Omaha & Grant Smelting & Refining Co., operating at Omaha, Nebraska, and Denver, Colorado; the Chicago & Aurora Smelting & Refining Co., operating at Chicago, Illinois; the Consolidated Kansas City Refining Co., operating at El Paso, Texas; and the American Smelting & Refining Co., now known as the Trust, in control of all but two of the foregoing mentioned smelting plants.

Each of these smelting companies had what I called its 'personal equation.' That is, some of them were more honest in the weighing, sampling, assaying, settling, etc., than others were. They had different ways of determining moisture, lead contents, etc., which ways were all calculated to be in favor of the smelter and against the shipper.

The first annual output from defendant's concentrating plant, the building of which was begun in 1890, was made with a loss in concentration of over 30% of the lead and over 33% of the silver. From that time on, it has been a constant effort and study not only to lessen the tailing-loss in concentration, but also to increase the lead content of the concentrates, so as to reduce the amount of worthless material upon which freight and smelting charges have had to be paid. In this effort, three concentrators have been built in addition to the first one of 1890. Of these four concentrators, the first one has been partly abandoned with its remaining portion partly modernized, the second one has been completely abandoned, the third one is being experimented with in the effort to work out a wet process for making a high-grade lead concentrate, and the last, or fourth one, is still being changed and modernized from time to time; and meanwhile has reduced the losses in concentration to eleven and a fraction per cent of the lead contents and to twenty-two and a fraction per cent of the silver contents. The wet process of concentration, now being commercially developed, promises to still further reduce these losses, to make a concentrate of approximately pure lead, and to recover in marketable shape some of the other valuable contents of defendant's ores.

Most of the old-time custom smelters were situated at such a great distance from Kellogg that a considerable cost was involved for freight. So, in 1898, the defendant company purchased an interest in the Tacoma smelter for the purpose of assisting in building up and putting that smelter on its feet; because freight-rates to that point were more favorable than the freight-rates at that time to other smelting-points, when taking into consideration the fact that Tacoma enjoyed a favorable water-freight rate on lead bullion to the Selby refinery at San Francisco, and then on refined lead from Selby by the Isthmus of Panama to New York. Tacoma thus not only had a great natural advantage in freight because

both of its nearness to Kellogg and of its situation for ocean competition; but the 'personal equation' of the Tacoma smelter had always been good. That is, it had gained a reputation among ore-shippers of returning fair weights, making correct assays, and in general making an honest settlement for all ore contracted for.

But by 1898 lack of working capital had rather put the Tacoma smelter out of the way of receiving a sufficient volume of ore to enable it to operate at a profit. Although this lack of working capital had resulted in the Tacoma plant running short of sufficient custom ores, still it had a splendid tide-water frontage which had been filled in with slag and a good upland acreage, and above all, a good name. At the same time that defendant purchased an interest in the Tacoma smelter, the Alaska Treadwell, Alaska Mexican, and Alaska United companies purchased a similar interest, ample working capital was arranged for, and contracts were made that afforded the Tacoma smelter 2000 tons per month of a very desirable iron-gold concentrate from the Alaska companies and an equal tonnage of lead products from the defendant, and at the same rate of profit per ton. This was all figured out at the time as a matter of equity, because the Alaska companies were paying for a third interest, the defendant was paying for a third interest, and individuals had already paid or were paying for the remaining interest, all of which payments were for the purpose of bettering and adding to the plant. This deal was tentatively started in 1898 in New York City by W. R. Rust, the then principal owner of the Tacoma smelter, securing the general approval of H. C. Perkins, for the Alaska companies, and the general approval of D. O. Mills for the defendant, these two men agreed to loan all working capital that might be needed in case the respective managements of the mining companies approved of the general arrangement. The details were then worked out on behalf of the Alaska companies by Thomas Mein, their then consulting engineer; on behalf of the defendant by myself; and on behalf of the individuals by W. R. Rust, many of whom had no interest whatever in the mining companies.

The Alaska companies and the defendant in purchasing into the Tacoma smelter in this way, provided that they would not only secure honest treatment for their respective ores and a fair share of the profits in smelting, but also funds for enlarging the smelting plant to enable it to do a large general custom business; as it was expected that the partnership of the mining companies with the Tacoma smelter would create such a prestige for the smelter as to enable it to secure many other ore-contracts. This prestige was especially successful in the case of the Alaska companies, as the Tacoma smelter virtually had from this start a monopoly on much of the copper ore shipped from Alaska. In fact, the tonnage of these shipments became so great that the resources of the Tacoma smelter were taxed in increasing its capacity fast enough to care for it, the expenditures on plant by January, 1905, having totaled some \$800,000. This constantly growing and profitable copper tonnage

eventually resulted in the building by the Tacoma smelter of the first and only copper refinery on the American shore of the Pacific Ocean.

With the prestige of this dividend-paying mining-smelter partnership, the Tacoma smelter not only secured an inside track on all Alaska smelting-ore shipments, but also South American, Mexican, and Oriental smelting ores gravitated to it. In addition, the Tacoma smelter was securing the shipment of silicious and other smelting ores from Nevada, Washington, Oregon, Idaho, Montana, and British Columbia. All this outside business had become so profitable that by January 1, 1905, the smelter was estimated as earning a profit of \$550,000 per year with nearly \$700,000 profitable annual earning capacity in sight.

Adjustments had been made from time to time in the Bunker Hill contract with the Tacoma smelter so as to continue the equity between the Bunker Hill and Alaska companies because of their respective interests in the smelter. One of these adjustments was made after one of the individual stockholders in the smelter threatened to bring suit on the ground that the smelter was not making as much profit per ton from defendant's ore as it was making per ton from the Alaska companies' ore.

The negotiations that culminated in the sale of the Tacoma smelter were begun in January, 1905, with W. R. Rust in New York City, by the officers of the plaintiff. Rust secured the signature of D. O. Mills (one of the large stockholders of the Tacoma company) to a document providing for the sale of his shares in the Tacoma Smelting Co. W. R. Rust then proceeded to San Francisco in the effort to secure the signature of myself, and of H. H. Taylor, the then president of the Alaska companies, to the same document. We would not sign the document presented, but afterward did sign an amended document, because D. O. Mills had committed himself to the sale and also because we had learned that the controllers of the plaintiff were also buying into the Selby refinery, and could thus embarrass the Tacoma smelter in the refining of its lead bullion. The sale of the stock held by the Alaska companies and by the defendant in the Tacoma Smelting Co. was neither sought nor recommended by Mr. Taylor or myself, but for the reasons stated we acquiesced in making the 25-year contracts for the mining companies, but upon the basis that the mining companies after a fixed five-year period would be given the benefit of competition. The purchasers refused at first to consent to any clause providing for competition, contending that they were taking the risks that the mines might play out; that silicious ores might become unavailable and that lead ores might become more plentiful. The last preceding annual report of defendant showed less than five years' ore in reserve, and plaintiff's agents made no examination whatever of defendant's mine.

Early in March, 1905, the negotiations had reached a point where the purchasers of the Tacoma smelter proposed that a smelting contract with defendant be drawn up on the following basis:

1st. Verbiage of then existing contract between plaintiff and defendant should be followed as near as possible.

2nd. The then existing contract between the Tacoma smelter and defendant to continue for 25 years.

3rd. Defendant to terminate its contract with the Salida and Carnegie plants.

4th. Defendant's contract with Selby not to be renewed.

5th. All ore above that containing the 27 to 37 (at option of defendant) tons metallic lead per day to be shipped to the smelter at Tacoma, to be settled on the terms as then existing between defendant and plaintiff for a period of 25 years, except that if after April 11, 1914, the plaintiff should pay for a majority of its ores in the Coeur d'Alene a better rate than its then existing contract with defendant, then after that date the same better rates should apply to tonnage in excess of any shipped to Tacoma and should change accordingly from time to time during the remainder of the contract, but in no case to be worse for the defendant than its then existing contract with the plaintiff, which did not cover any ore of 40% and under and 70% and over.

The negotiations continued until March 29, 1905, when it was agreed that competition was to become effective after the fixed 5-year period expiring June 1, 1910, for all ores, concentrates, and slimes between 30% and 75%, including the tonnage to the Tacoma smelter as well, with the understanding that defendant was always to receive thereafter at least as good rates as those provided for in the fixed 5-year period and in addition thereto was to receive from time to time any and all benefits established by competition.

It was finally agreed that the essence of the contracts with the mining companies was to be a continuation of the then existing terms for five years, with the provision that after the expiration of the fixed 5-year period, the Alaska companies and the defendant were each and all to obtain the benefit of competition, and paragraph 12 was inserted in defendant's contract (Exhibit B to the complaint) and paragraph 7 was inserted in the Alaska companies' contracts (Exhibits C, D, E to the complaint). It was recognized that the Tacoma smelter was the only practicable outlet for the concentrates of the Alaska companies, and that if they secured any competition at all they would have to create it; but nothing whatever was said at the time about the cyanide process, and it was not in my mind and not talked of by any of the negotiators that it would be feasible or possible for the Alaska companies to create their own competition. This was only accomplished after some three years of experimental work begun in 1908. This work resulted in the following notice:

"San Francisco, Nov. 4, 1910.

Tacoma Smelting Company,

Tacoma, Washington.

Gentlemen:

We inform you that we are now able to treat the products of our mine in such manner that the profits

will be greater than by selling you the concentrates, in that we can treat the concentrates at Douglas Island, Alaska, for a cost not exceeding \$3 per ton, and will save \$2.89 per ton on freight, insurance, and other charges, and the extraction will be 98% and considerable value in cyanide residues for their iron and sulphur contents, and we would have the immediate use of money for the concentrates, which would be equivalent to interest on their value for from 30 to 60 days.

We hereby notify you that if, after a period of three months from the date of this notice, you refuse to accept the concentrates agreed to be delivered under our agreement dated March 20, 1905, and to make returns and render accounts therefor at such prices as will give and yield us as great net returns for such concentrates as can be obtained by us by our present method of treating them at Douglas Island, without cost of freight, insurance, and other charges, and loss of interest and loss of iron and sulphur contents, we will, upon the expiration of said notice, forthwith terminate such agreement and cease to ship and deliver to you any concentrates under it.

We inform you that we are keeping an account of tonnage for final adjustment with you in event that you refuse to take the concentrates as stated in our agreement and in this notice.

Very respectfully,

to market its entire output; but I was willing to have the exclusion of the products of 30% and under and 75% and over because a low-grade lead product was always especially sought after by near-by smelters and the special reservation of ores carrying 27 to 37 tons of metallic lead per day to the Tacoma smelter was to be sure of maintaining a lead-smelting point at Tacoma. Also, a high-grade lead product could stand shipment to a distance at which competitive smelters might be reached.

The idea of providing for the same yearly average analysis and lead assay as the ore shipped in any one year of the preceding 12 years was to be sure of being able to deliver to the smelter any possible mixtures of ore. That is, if an ore carrying 30% of lead and under could not be sold locally and if an ore carrying 75% in lead and over could not be sold at a distance, then these two products could be mixed to fit the average of any one of 12 preceding years. This was further provided for by the clauses reserving the options as to making shipments to any smelting plant; and as to lead contents of ores, slimes, and concentrates wherever the same might be shipped; and also by the clause reserving the right of putting different classes of product together to form a shipment.

At the time of the Baruch-Tacoma deal, defendant had five outstanding contracts as follows:

Quantity and character of tonnage	TACOMA SMELTING CO.	OHIO & COLORADO SMELTING CO.	PENNSYLVANIA SMELTING CO.	SELBY SMELTING & LEAD CO.	AMERICAN SMELTING & REFINING CO.
	Ore and concentrates containing 27 to 37 tons daily at option of defendant.	Concentrates shipments unlimited, defendant to cease at any time.	Highest grade of ore and concentrates not less than 600 tons per month and not more than 1000 tons per month.	Ore and concentrates maximum 1000 tons per month and minimum to contain 200 tons lead per month.	Ores, slimes, and concentrates to be of a lead-assay value of between 40 and 70%, unless the smelting company should give its written consent for shipment to it of ores, slimes, and concentrates varying from that lead-assay standard; 40 tons daily minimum; maximum unlimited.
Life	Two years from June 1, 1904, plus 5 years additional contingent.	Two years from Feb. 2, 1904.	May 9, 1904, terminable 30 days' notice from either party.	Jan. 1, 1903, for 5 years.	Five years from April 11, 1904.
Payment	90% of lead contents at 90% of N. Y. price up to \$4.10 plus ½ of the excess above.	100% of full fire-assay value. Per unit 25-40%, 40c. 40-45%, 44c. 45-50%, 52c. 50-55%, 56c. 55-60%, 57c. 60 and over 60c. at lead basis of \$4.25. Variation 1c. per unit from prices given for every 5c. variation from \$4.25.	90% of contents at full N. Y. price.	90% of lead contents at full N. Y. price.	90% of the lead contents at 90% of N. Y. price when 4.10 or less plus ½ excess when over 4.10.
Freight and treatment charges	When gross values not \$50, \$16 plus or minus ½c. per lb. of lead variation from 53% lead.	Gross value \$50 and less, \$10 p.t. \$50-60, \$12 p.t. \$60-100, \$14 p.t.	\$21.50 released to \$80 gross valuation based on \$12 freight-rate.	\$18 based on \$8 freight-rate.	\$8 for treatment plus railroad tariff-rate to Denver or Pueblo whatever the destination.

ALASKA TREADWELL GOLD MINING Co.

(Signed) H. H. TAYLOR,

President.

With the Everett smelter secured by the Federal Mining & Smelting Co., and with the control of this company secured by the same control that was securing the Tacoma and Selby smelters, I knew that a great monopoly was being built up in the lead-smelting business and that the contract for defendant's ore then being negotiated must provide for defendant being able

Large shipments of crude ore were being made to the smelters at Tacoma, Everett, and East Helena; and the average freight and treatment rate under all above contracts was better for defendant than the average rate for ores, slimes, and concentrates of between 30% and 75% lead as fixed in the Tacoma smelter 25-year contract.

The Tacoma smelter in July, 1905, arranged to take 3000 tons per month of our crude ore at Tacoma, 1200 tons per month at Everett, and 1300 tons per month at East Helena.

The Tacoma company a short time later desired to change the clause that permitted us to ship crude ore to the Tacoma smelter, as well as that permitting us to ship slime and any other product, amounting to 37 tons of metallic lead daily, and they offered concessions in this regard provided the Bunker Hill would change contract Exhibit B so as to make it cover the defendant's entire product. I declined to consent to changing the contract in this respect.

About this time a controversy arose over our option under the original 25-year contract to make deliveries at any smelting plant of any character of product. We insisted that we had the option to determine the lead contents of ores, slimes, and concentrates wherever the same might be shipped. The contract so provided. We considered this option vital because of what I have already described as the 'personal equations' of the different smelting plants. We had it in our power to ship different grades and character of products to the different plants according to their different degrees of honesty in determining weights and lead contents and in making payments.

Late in the year 1905 a controversy arose over our shipments of high and low-grade concentrates containing less than 30% in lead and over 75% in lead to the Ohio & Colorado Smelting Co. and to the Pennsylvania Smelting Co. This controversy extended until March or April, 1906, when the right of the Bunker Hill company to ship to outside smelters material containing 30% and less and 75% and more in lead was clearly established and conceded as shown in the exhibits attached to defendant's answer. From the year 1906 until the year 1915 the Tacoma company met competitive bids made by other smelters for our high and low-grade products and the parties recognized the construction which the parties in the year 1906 placed upon the clause of the contract pertaining to high and low-grade shipments to outside smelters.

In the year 1908 it was arranged that an examination of defendant's mine and concentrating plants should be made by Pope Yeatman, one of plaintiff's consulting engineers, who reported among other things, as follows:

\* \* \*

"CONCENTRATION. The crushing stations and concentrators are situated in the valley just beyond the mouth of the Kellogg tunnel. There are now three mills. The old one of a nominal capacity of 900 tons per day; the new or south mill of about 600 tons per day averages for the entire year including delays, and a tailing plant (West mill) estimated to be able to treat 900 to 1000 tons of tailing.

"At the present time there is being operated the new plant, a part of the old plant, the other portion being overhauled, after which the part now in operation will be also overhauled and the tailing-plant which is being operated in connection with the old plant, taking the finer material for final treatment. When repairs and alterations are completed in the old plant, each one of the plants will be self-containing and absolutely inde-

pendent and able without the others to handle its own particular feed.

"An excellent description of the new plant by the superintendent, Gelasio Caetani, can be found in the 'Mining and Scientific Press' of January 15, 1910."

\* \* \*

"The new mill is thoroughly up to date and well-designed and the old mill will also be brought into excellent condition. In the last few years considerable improvement has been made in concentration over the old operations and while costs have been increased, partly due to the 8-hour law going into effect and also to the greater number of machines used to better extraction, the increased saving has more than justified the greatest cost." \* \* \*

"The products produced are first, hand-sorted ore, done principally in the stopes, but also on belts at the crusher-stations; second, coarse concentrate; third, middling high in carbonate of iron, but for which there has been a market at the smelters; fourth, slime concentrate. The utilization of the middle products has made higher extraction possible than would have been the case had it been necessary to separate these." \* \* \*

Toward the end of February, 1910, the question was raised of arranging the new prices after the expiration of the 5-year period on June 1. W. R. Rust wanted the new arrangement to cover the high-grade product at the rates then in force, but I claimed that defendant was entitled to better rates. At a meeting in San Francisco with Judge Lindley, Edward Brush, E. L. Newhouse, and Karl Eilers, I asked for the rates that plaintiff was then granting the Hercules and made the contention that plaintiff was not buying the majority of Coeur d'Alene ores, as Tacoma and Selby were outside smelters according to the wording of the contract, and that therefore defendant should get the benefit separately of every item in the outside contracts that would better the corresponding items in the 25-year contract. I finally covered all of my contentions to the specific claim of a betterment of \$1.70 per ton. This contention resulted in the fourth supplemental agreement of November, 1910, which was the result of a compromise in splitting my claim to 85 cents per ton, without prejudice; but this was to cover only our products of 30% and under and 75% and over which were left free for outside smelters. This agreement was made retroactive to begin June 1, 1910, and to expire five years thereafter, on June 1, 1915.

In June 1912 I notified the Tacoma company that under a misapprehension of instructions the shipments theretofore made to the Tacoma smelter were being sent to East Helena at a saving to the smelting company of about \$2.25 per ton. I claimed either the benefit of this freight reduction or else the right of shipping to the Tacoma plant material to contain a maximum of 37 tons of metallic lead per day. At the same time I also notified the Tacoma company that the competitive freight and treatment rate on the high-grade product was \$15 per ton and not \$18.50, which the Tacoma smelter was then charging us. With these notifications, I thereupon

placed the specific carrying out of our contentions with our attorney, M. A. Folsom, and our manager, S. A. Easton, who thereupon secured the competitive rate for the high-grade output for an unlimited tonnage to last until June 1, 1915, in consideration of which we waived for the time being, without prejudice, either our right to ship up to 37 tons metallic lead daily to Tacoma or the \$2.25 difference in freight-rates between shipping to Tacoma and to East Helena.

Toward the end of 1912, it became apparent that plaintiff was limiting all its ore-contracts so as to have them expire on or before June 1, 1915. The uncertainty of competition after June 1, 1915, caused me in November 1914 to authorize M. A. Folsom to endeavor to reach some understanding with Tacoma in advance; and in December 1914 I notified the plaintiff that Mr. Folsom had full and sole authority to act for defendant in endeavoring to reach some understanding for the disposal of our ores after June 1, 1915. These negotiations extended for several months without result. It was then that defendant decided to build its own smelter and construction contracts for that purpose were entered into in September 1915.

Plaintiff's letter signed by Edward Brush, which is set forth in the complaint, warning us not to erect a smelter, was dated New York, November 22, 1915; but we had then already let our contracts, after being unable to secure any other outlet for our product. In spite of the great revival in industry, war prices for lead, and demand for ores, we could secure no bids whatever for any of our product. Therefore it was absolutely necessary for us to continue with our plans to construct a smelter in order to provide some market for our high and low-grade products; for the ores of a grade too low to ship to a distance; for the disseminated ores that it would not pay to concentrate before smelting; for the disposal of sufficient quantity of material to yield 37 tons of metallic lead per day, which had been refused at Tacoma, and to provide competition for the remainder of our ores should the plaintiff herein continue to deprive us of the competitive rates provided in clause 12 of our contract.

Defendant accordingly erected a smelting and refining plant near Kellogg, Idaho, where it is now working satisfactorily on lead ores some of which carry 8% zinc. Kellogg is the centre of one of the important lead-mining districts of the United States and is the logical point for a lead-smelting plant. Defendant's smelter will not only be a help to old Coeur d'Alene mines, but will stimulate the prospecting for and discovery of new mines which will probably be developed as fast as old ones are worked out. This prediction is based on the fact that since the making of the Tacoma contract the following comparatively new Coeur d'Alene mines have become productive: Consolidated-Interstate Callahan, Green Hill-Cleveland, Marsh, Ontario, Stewart, Tamarack & Custer, Caledonia, Sierra Nevada, and Alhambra.

Also, defendant's mines for the 12 years, 1905-1916 inclusive, have averaged about three times as much ton-

nage of shipping product as they averaged in the 12 years prior to 1915. All this increased lead production from the Coeur d'Alene district has resulted in the following lead production for the State of Idaho, as compared with the total production of the United States:

	Idaho tons	United States tons
1894 .....	33,308	213,650
1895 .....	31,638	235,822
1896 .....	46,662	257,487
1897 .....	58,627	282,169
1898 .....	59,142	302,148
1899 .....	52,154	298,047
1900 .....	85,444	367,773
1901 .....	79,654	371,032
1902 .....	84,742	367,892
1903 .....	99,590	368,939
1904 .....	108,854	393,452
1905 .....	99,027	388,307
1906 .....	117,117	404,746
1907 .....	123,292	413,389
1908 .....	98,464	396,564
1909 .....	103,747	446,909
1910 .....	109,951	470,272
1911 .....	117,355	486,979
1912 .....	127,780	480,894
1913 .....	137,802	462,460
1914 .....	177,827	542,122
1915 .....	160,680	550,055
1916 .....	170,059	571,134

The foregoing tabulation discloses that the Idaho production for the last 11 years has increased at about the same rate as has the production for the whole United States. On the other hand, the production of Missouri has, for the last 11 years, increased twice as rapidly as has the production for Idaho. One reason for this is because of late years the controllers of plaintiff have secured control of lead-mining property in Missouri and largely increased the output of such property. In this connection, plaintiff's annual report for the year ending December 31, 1916, says:

"Due to the falling off in the lead ore coming to the company from the Coeur d'Alene mines, attention has been given to increasing the supply of lead from other sources. About three-quarters of a million dollars have been expended in enlarging the milling and smelting works, and extending the development of mines of the company in Missouri. While the production, from this source, at the beginning of 1916, was approximately 42,000 tons of pig-lead per annum, this has now been increased to 66,000 tons. Constant attention is being given to the increasing of the supply of lead ore at the disposal of the company."

Defendant's last annual report shows ore reserves blocked out totalling 3,453,146 tons, with bottom level of defendant's mine in the best orebody that it has ever enjoyed. As this is eight years' life at the present rate of output, with geological conditions in favor of many years of additional life, defendant is fully justified in increasing the efficiency of its plant in order to fortify itself against periods of low prices for lead. This increase of efficiency is economically necessary.

# REVIEW OF MINING

## CRIPPLE CREEK, COLORADO

CRESSON CON.—GOLDEN CYCLE.—EXCELSIOR.—PRIDE OF CRIPPLE CREEK.

Meetings will be held during the ensuing week by the directors of the Cresson Consolidated Gold Mining & Milling Co., and the Golden Cycle Mining & Reduction Co., when in addition to the declaration of the regular monthly dividend, payable December 10, it is confidently expected the directors of these companies will pass upon the payment of an extra, or Christmas, dividend. The Cresson company has paid 11 consecutive monthly dividends of \$122,000 each this year, and the Golden Cycle company 11 dividends of \$45,000 each. A. E. Carlton of this city is president of both corporations.—Active operations will be resumed by the Catherine Mining Co., on the Last Dollar mine on Bull hill, under bond and lease to the Catherine company. At the annual stockholders' meeting at Victor, the following officers and directors were elected: C. R. Street, president; H. C. Eddy, vice-president; John A. Gallagher, secretary and treasurer; C. Harding and W. Bigby directors. All reside at Chicago. Charles Walden of Victor was re-appointed general manager.—The Excelsior Mining, Milling & Electric Co. has purchased the six-drill electrically-driven compressor formerly in use at the Sitting Bull shaft of the Hondo G. M. & M. Co., and the machinery has been removed to the Longfellow mine on the eastern slope of Bull hill. The Hondo company has ceased operations.

The Pride of Cripple Creek, on the eastern slope of Ironclad hill, has been leased by the Pride of Cripple Creek Gold Mining Co. to E. H. Beebe, L. S. Cox, and Harry Nelson, well-known mining men of this district. A 30-hp. electric hoist has been erected and operations have commenced. The Pride is in close proximity to the Jerry Johnson, W. P. H., and Forest Queen mines, all producing at this time.—A block of the Cresson property, situated on the north end of the Sadie Bell and Draper lode mining claims, above the 1100-ft. level of the Cresson shaft, has been leased to Evan Williams, Edward Olsen, and J. Anderson of this district, who are operating the block from the 1450-ft. level of the Jackson shaft of the Gold Sovereign Mining & Tunnel Co. on Bull hill.—The Hahnswald Leasing Co., operating the Gold Sovereign mine, is pushing development on the 1450-ft. level of the Jackson shaft, and the drift on the main Sovereign vein is showing well.—The Big Toad Mining & Milling Co., operating the Dante mine, adjoining the Gold Sovereign M. & T. Co., on Bull hill, has opened up a strong body of milling-grade ore.—The Rex mill on Ironclad hill has been closed down for the winter months.—A telegram received from Clark G. Mitchell, director and manager, Isabella Mines Co., announced his voluntary enlistment with the U. S. Aviation Signal Corps at Washington, D. C.

## HOUGHTON, MICHIGAN

THE PRICE OF COPPER.—SENECA.—LA SALLE.—BAL TIC.

The production of copper from Lake Superior mines for 1917 is estimated at 225,000,000 lb., provided nothing unforeseen intervenes.—There is much speculation in the district as to what action the Government will take relative to the price of

copper at the conclusion of the present agreement which ends January 1. That there can be a further reduction in the price seems out of the question, as it would mean suspension of more mines or a cut in wages. The mines now are paying good bonuses to their employees, and while no official announcement has been made, there is every reason to believe they will continue to do so. Few of the mines are working

MICHIGAN COPPER BELT

full forces, and all of them could use more men to advantage. Should the Government decide upon a lower price for copper there could be but one logical outcome, namely, Government control of the mines. This would necessitate, not the operation of the mines by the Government, but a supervision over general conditions with a stipulated percentage of profit allowable to the shareholders. Such a profit would undoubtedly be based on amount of copper produced, as all energy would be directed to a large output. Lake Superior mining men believe that stimulation to production might be secured by increasing the price to 25c. per pound, but they hardly expect any such action.

While the official announcement says that the Keweenaw has shut-down only for the winter, and while it may re-open

in the spring, the fact is that the Keweenaw is close to the end of the rope. Its copper content has been about 12 lb. per ton and the tonnage limited at that. It has been a long hard pull and the shareholders have stuck with tenacity to their hopes for better things. The present company was organized by the late Charles A. Wright and, as originally planned, it contemplated operations on a large scale.

A 10,000-kw. turbine has been shipped and will be set up at Lake Linden power-plant of the Calumet & Hecla.

The costs at Franklin are now 17c., despite high wages and costs for material. The sinking at No. 2 shaft will be under way this week. The production from No. 1 shaft is better than 1100 tons per day.—Production of White Pine for 1917 will be over 4,000,000 lb., about equal to that of last year.—The accumulated stock-pile at the Wyandott will go to the Winona stamp-mill next week.—The Franklin has made various improvements at the mill, which facilitates operations and ensures economies. The latest is the longer trestle, permitting 16 cars.—Production at the Hancock for November will be 340,000 lb. The mine could use an increased force of one-third underground. There is no indication of any immediate betterment in the labor situation.—The Seneca has practically completed housing in its surface plant, which is one of exceptional capacity. Shaft-sinking will start on January 1; the shaft-house is completed; railroad track being laid; and hoisting-engine foundation was laid early in the month; boilers are now being erected.—The future possibilities of development of rich Osceola lode extension from No. 6 shaft Osceola into La Salle territory are bright. Ore of more than ordinary quality is now showing, but mining is difficult, because of the great depth and long distance from the shaft.—The No. 7 shaft at Isle Royale is being sunk below the ninth level. Three levels south are in over 600 ft. in average ground, not quite up to the quality of No. 5 shaft.—The Baltic mine is coming into good ore again in the No. 4 shaft at the 32nd level. At No. 5 shaft, the best ore is coming from west vein. The best producing shaft both in quality and quantity is No. 2, half of the output coming from this shaft. Practically all of the tailing from the three Copper Range mines, Baltic, Tri-mount, and Champion, are being re-ground.

## MAMMOTH, UTAH

A. S. & R. Co. BUYS MORE ORE.—SCOTIA.—PLUTUS.—SCRANTON.

The Emma Consolidated property is in a splendid condition. The winze, which is now 45 ft. below the third level, has cut good-grade ore running 100 oz. silver and 5% lead. Recent analyses show the ore to contain tungsten and molybdenum, one assay running 26% tungstic acid.

Certificate of amendment to articles of incorporation of the Monarch Mines Co. has been filed with the county clerk. The capital stock is increased from \$40,000 to \$62,500, in shares of the par value of 5c. Charles Othram is the president and J. W. Storrs secretary of the company.

The Six Mile Mining & Milling Co., operating in the West Tintic district, has made an important strike in a new shaft. The vein is over 5 ft. wide and carries from 25 to 160 oz. silver and 60% lead. The shaft was sunk as a test, and as soon as ore was found a cross-cut was started from the 200-ft. station in the adit which is expected to cut the orebody at a vertical depth of 350 feet.

Rapid speed is being made in sinking the main working-shaft on the property of the North Beck Mining Co., in the North Tintic district. Sinking started on October 17, and now the shaft is nearing the 250-ft. level.

The Tintic Standard is mining ore from the new workings north of the new shaft. The orebody is large and assays 70 oz. silver, \$6 gold, 10 to 12% lead, and 2 to 3% copper. This new work proves the orebody to have a length of over 400 feet.

While the American Smelting & Refining Co. has notified

some of the local mines, among them the Eagle & Blue Bell, that the embargo has been lifted, notice has been given that only a limited tonnage of ore will be accepted until conditions change. The Eagle will probably be allowed to ship three carloads of ore per day, which is less than half what the mine should be sending out. Other Tintic properties which have been shipping to this smelter will receive similar treatment and officials of the smelting company believe that by holding the mines down to a smaller tonnage it will not be necessary to shut them off periodically as they have done in the past. The general outlook for the mines of this district is more promising than it has been for some time, although a weak lead market is a serious drawback, most of the mines being heavy lead producers.—Walter James, owner of the Scotia mining property in the West Tintic district, has sold his interests to Dunn & Fabian, of Salt Lake City. At the time the Chief Con. was operating the Scotia it took out \$100,000 worth of lead-silver ore, paying the Scotia company in royalties \$20,000. The ore was followed to a depth of 400 ft. by a winze sunk some distance below the 150-ft. level, where the ore was not lost. The new owner will continue the winze and will prospect about 300 ft. of undeveloped ground between the main workings and an old glory hole from which M. S. Sammon quite recently took a couple of shipments of good ore. James McNelis is to be the superintendent.

According to Preston Peterson, superintendent, the Big Indian mill has been fully demonstrated, and as soon as minor repairs are made, the mill will be started. The payroll of the company will be increased to at least 200 men.—W. D. Loose, local manager for the various Loose properties, states that a drift is being sent out to cut the vein in the Central Hill ground at a depth of 285 ft. Nearly 100 ft. above this point the company did some driving with encouraging results. The Central Hill adjoins the Mammoth, Grand Central, and Plutus.—Work is being carried on in five different points at the Plutus, according to officials of the Chief Con. Co., which now controls it. After driving into the Plutus from one of the lower levels of the Victoria a raise is being put up to thoroughly prospect a body of quartz. Another section of the Plutus is being developed from the old Tetro shaft, which recently was cleaned out and re-timbered. This shaft has a depth of 400 ft. and the showing is so promising that extensive driving will be done before sinking the shaft to a greater depth.—Mining operations at the Scranton, in the North Tintic district, have been slowing down somewhat during the past month as a result of the decline in the price of lead, most of the ore taken from the mine being low grade. For the past two years lessees have been busy in the Scranton and have shipped a large amount of ore; the output running near 100 tons per week. Announcement of another assessment of 1c. per share on the stock of the Eureka Lily Mining Co. has been made. This assessment will be delinquent on December 19 and the sale day is January 15.—The Copper Leaf officials have decided to handle the shaft work on company account when the present contract expires. The shaft is now down to a depth of 400 ft. The ground is hard and sinking slow.—On November 24, when the Chief Con. was crowding things to get out as much ore as possible under its old contract, which has since expired, it came close to establishing a new record for fast hoisting, bringing out of the mine 415 mine cars of ore in an 8-hour shift.—Shipments of first-class ore from the Tintic district show an increase of 11 cars, the total being 230 cars as against 219 the week previous. This week's shipments are valued at \$275,000. The car shortage has ended, at least for the present. The principal shippers this week were: Chief Con., 50 cars; Dragon Con., 42; Iron Blossom, 26, Mammoth, 16; Gemini, 16; Centennial Eureka, 14; Grand Central, 11; Gold Chain, 10; Eagle & Blue Bell, 8; Tintic Standard, 7; Bullion Beck, 5; Colorado, 5; other mines, 20 cars.—The Eureka Standard Mining Co. has given to the Eureka Standard

Consolidated Mining Co., for 350,000 shares of the latter, quit-claim deeds to the Mielich or Montana group of claims.—The Bullion Mining Co. has withdrawn the 1c. assessment, recently levied.—Work at the mines of the Western Utah Extension Copper Co. is being pushed under more favorable conditions and the showings in all the workings are better than a week ago. The ore in sight has been increased and some high-grade ore is being mined from a new opening on the Helmet vein.—Sinking is to be resumed immediately by the Pole Star Copper Co. in the Victor shaft, and the work will be pushed until a depth of 500 ft. is reached. The shaft is 150 ft. deep and from that point driving to the west and north is under way.—High-grade ore carrying copper, silver, and gold is still being followed from the bottom of the 75-ft. winze in the Copperopolis mine of the Bamberger-Dunyon. A drift is being sent to the south in the fissure containing the rich ore that continues to show strength.—A new discovery of ore was made this week by the Woodman Mining Co. when work was started on the west side of the ridge from where the main operations of the company have been carried on. The ore carries 8 to 9% copper.—A contract to sink the Moonlight No. 4 shaft 100 ft. has been let by the Deep Creek Copper Mining Co. to Oscar Carlgren of Gold Hill, who has moved a whim to the property and is arranging to work two shifts. The shaft is about 20 ft. deep and follows a small vein carrying a good-grade copper ore.

## MONTERREY, MEXICO

### DESTRUCTION OF GUANAJUATO POWER-PLANT.

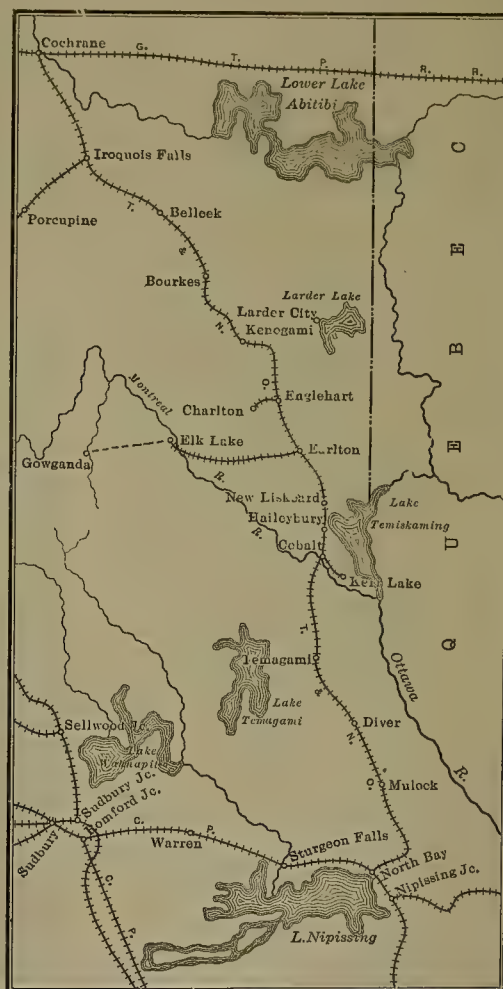

American mining men have recently fled from Guanajuato to escape the possibility of falling into the hands of a large force of Mexican bandits who are operating in that section. The Americans state that this great mining district is now in a more chaotic condition than it has been at any time since revolution and brigandage began in Mexico. The most serious aspect of the present situation in the States of Guanajuato, Michoacan, Jalisco, and San Luis Potosi grows out of the recent attack that forces of brigands made upon the great hydro-electric plant of the Guanajuato Power & Light Co., situated at El Duro, State of Michoacan. They destroyed the turbines and other valuable machinery and put the entire plant out of commission. Not contented with this destructive work, the bandits cut and carried off large sections of the power-transmission cable. The power company owns three generating plants; all connected into one system with a number of sub-stations, by means of which power is conveyed and distributed over a wide area of central Mexico. The mines and ore-mills of the rich Guanajuato district, the irrigation plants of the plateau region of Jalisco, the flour-mills and smelters of Aguas Calientes and portions of San Luis Potosi, as well as the industrial establishments and towns of these several States, were dependent wholly upon the Guanajuato Power & Light Co. for their service. As a result of the partial destruction of the plant and the severing of the transmission lines by bandits, the mines and other industries have been compelled to shut-down, and it will probably be several months, even under the most favorable conditions, before the damage can be repaired.—The bandits in the Guanajuato region are commanded by Inez Chavez in the guise of revolutionists. They have committed robberies within the city of Guanajuato and practically hold that place within their grasp.—El Duro, where the central hydro-electric plant of the power company is situated, is 120 miles from the city of Guanajuato. The company is composed of Americans, most of its stock being owned by Colorado Springs men. It was through this development of cheap electric power that a great revival of mining operations in the Guanajuato district was brought about some twenty years ago. This cheap power has also enabled the reclamation of large areas of land by means of irrigation and

has been in this and other respects of enormous benefit to the people of that part of Mexico.

## COBALT, ONTARIO

MCKINLEY-DARRAGH.—HOLLINGER.—MCINTYRE.—DOME.

The McKinley-Darragh is meeting with excellent results at the 400-ft. level. Considerable high-grade ore is being found and there is a large tonnage of low-grade in sight. The company has declared its regular dividend of 3%, payable January 1, to shareholders of record December 8. This makes a total

COBALT AND PORCUPINE DISTRICTS

for the year of \$269,723, or an aggregate of \$5,146,197, which is equal to 229% on the company's capital.—The Coniagas is yielding 108,479 oz. of silver per month. The Ankerite and the Maidens-McDonald property, which are controlled by the Coniagas, are developing satisfactorily.—The Miller Lake-O'Brien mine of Gowganda, which, like the O'Brien mine at Cobalt, is under the control of M. J. O'Brien, Ltd., a twenty million dollar corporation, is rapidly taking a place of honor among the best mines of northern Ontario. The production from the Miller Lake is averaging about 84,000 oz. per month.

The sensational developments at the Hollinger Consolidated during recent weeks, have revealed an enormous orebody at the 400-ft. level. At the 200-ft. level this body was 60 ft. wide and high-grade. At the 400-ft. level the width has increased to

70 ft., and the average gold content is understood to be \$27 per ton. When it is remembered that previously the average grade throughout the mine was less than \$9 per ton, the importance of a 70-ft. body of \$27 ore can be realized.—The McIntyre-Porcupine continues to hold its strong position. A net profit of \$70,000 per month is being maintained and with a steadily increasing ore-reserve and better facilities for the handling of its ore, the McIntyre company should be able to continue the present rate of dividend disbursements. This mine, in point of production, is second only to the Hollinger. —The Dome Mines is not being operated at full capacity. The shortage of labor and the low grade of the ore, preventing its being handled during times of high costs, have forced curtailment. However, the ore-reserve appears to give abundant assurance of the intrinsic value of the mine.—The Porcupine V. N. T. is in full operation and results are better than ever in its history. The 100-ton mill is running at normal capacity and the grade of ore is nearly \$10 per ton. Recent developments at the 600-ft. level of this mine have been good.

### DEADWOOD, SOUTH DAKOTA

#### IMPROVEMENTS AT TROJAN CYANIDE MILL.

Two important purposes are being served by the improvements now being made at the mill of the Trojan Mining Co., at Trojan, namely, increased recovery and greater capacity. When these changes are completed the flow-sheet will be about as follows: the crusher product will go to two 6-ft. Chilean mills, one of which will discharge to the closed circuit of a ball-mill and Dorr classifier; the sand to leaching-vats, and the slime to a series of thickeners and agitators, employing counter-current decantation, with final wash and de-watering of the slime on Portland filters. Fine grinding, or 'all-sliming,' will not be attempted, for experiments have demonstrated that fine sand yields as economical an extraction as slime—that is, the extra expense of reducing the ore to slime is not offset by the increased recovery effected. This conclusion is based upon the value of the mill-feed, which is \$4 per ton, and probably would not apply to ores worth twice as much. It has been determined that a 60-mesh sand yields a satisfactory recovery of both gold and silver, and with the purpose of grinding as much as possible of the ore to that fineness and at the same time producing a minimum of slime, the new flow-sheet has been designed.

The cyanide solution is mixed with the ore in the proportion of 3.9:1 at the Chilean mills, of which there are two, of the Trent-Monadnock type. From one of the mills the pulp is taken direct by elevator to the classifying department, while the other discharges to a Dorr classifier, operating in closed circuit with a Denver Engineering ball-mill. The discharge from the ball-mill enters the same classifiers; sand from this is returned to the ball-mill, and the slime enters the main classification department, being carried there by a steel-cased elevator and a series of launders. A feature of the ball-mill is a combined scoop and centre feed which permits the feeding of either ore or sand as desired. The scoop has a radius of 38 in. The 20-in. trunnion-discharge can be closed by plates to give any height of discharge. The lining was designed in the Trojan office and eliminates a large number of the bolts ordinarily used. Between the motor and the mill pinion is a shock-absorbing gear, designed by the Denver Engineering Works.

As has been noted, the pulp coming to the main classifiers is comprised of material that will pass a 60-mesh screen. An attempt is made to separate this into pulp larger and smaller than 150 mesh; the larger going to the sand-treatment vats and the smaller to the slime department. Naturally it is impossible to make a clean separation—the sand always containing more or less slime, and the slime some fine sand—but the theoretical point is adhered to as closely as possible. In the

classification department are a 16-ft. Weigand and two Dorr duplex classifiers. The Dorr machines are of the ordinary type. All of the details of the slime-treatment have not been worked out. The department includes 5 vats, 40 by 14 ft., equipped with Dorr thickeners. Two of these will probably be used as primary units, to de-water the classifier product, while the others, together with agitating-tanks, will form the counter-current decantation system. They are equipped with Colorado Iron Works diaphragm-pumps for handling the thickened slime. From the counter-current decantation system the slime will go to three 12-ft. Portland filters, now being erected. These machines will de-water and wash the slime. Among other important additions to the plant is the doubling of the precipitating facilities. Three additional steel zinc-boxes are being added. Another tank with filter-leaves is to be put in for clarifying thickener-overflows before precipitation. The mill is expected to treat 400 to 500 tons daily. It does a custom business, for which it is well equipped, as receiving-bins, sampling department, and laboratory are all well adapted to the careful handling of custom business. Recently the Two Johns property was purchased and is being developed and equipped. At Blacktail the company has secured the Republic mine under a long-term lease; this may develop into a large producer.

### TONOPAH, NEVADA

#### TONOPAH MINING CO.—TONOPAH BELMONT.—WEST END CON.—

The Tonopah Mining Co. during October milled 11,400 tons of ore, averaging \$9.43 per ton, resulting in a net profit of \$17,075. During the week ended November 24, 2550 tons of ore, averaging \$8.50 per ton, was milled. In the Silver Top 84 ft. of development has been done, 26 ft. in the Red Plume, and 129 ft. in the Sandgrass. On the 340-ft. level of the Silver Top, stoping continues on the Valley View vein on a 3-ft. face, while on the 640-ft. level the stope on the Burro vein shows a 3-ft. face. On the 1300-ft. level of the Sandgrass the west drift on the Merger vein continues in quartz. A drift to the east has been started. Last week the production was 2750 tons.—The Tonopah Extension Mining Co. during October milled 9393 tons of ore, resulting in a net profit of \$13,288. In the No. 2 shaft 111 ft. of development was done and 103 ft. in the Victor. At the No. 2 on the 850-ft. level, raise No. 814 advanced 15 ft. on a 2-ft. stringer of ore. On the 1260-ft. level raise No. 453 advanced 20 ft. on a 3-ft. face of ore. On the 1680-ft. level of the Victor 1600 south cross-cut advanced 7 ft., while 1600 east drift advanced 7 ft. on a 3-ft. face of ore, and west drift 1600 continued on a 4-ft. face of ore. The production for the past week was 2380 tons.—The Tonopah Belmont Development Co. milled during October 10,087 tons of ore, resulting in a net profit of \$51,876. On the 800-ft. level raise No. 16 shows a 4-ft. face of ore, while raise No. 17 continues on a 6-ft. face of excellent ore. North-east cross-cut No. 8013, which started from the Occidental vein, cut the South vein exposing 2 ft. of medium-grade ore. At this level the South vein was intersected by cross-cut No. 8014 at a point farther east, showing 3 ft. of low-grade ore. On the 900-ft. level the north-east cross-cut, after picking up the faulted segment of the Occidental vein, was continued to find the faulted segment of the South vein. On the 1000-ft. level raise No. 72 on the Rescue vein broke into the level above. The raise proved the vein to be 4 ft. wide, consisting of medium-grade ore. Last week's production was 2372 tons.—The West End Consolidated Mining Co. continues development at the Ohio shaft. Raise No. 3 on the 555-ft. level made connection with the level above. Drift No. 1 continues in fair ore. On the 500-ft. level the excellent showing, where the 506 cross-cut intersected the vein, continues in the drifts started last week. A the West End shaft drift 717 No. 2 continues on a face of low-grade quartz. The output for the past week was 1211 tons.

## ALASKA

The annual meeting of the Alaska Mining and Engineering Society was held on October 17, 1917, at Thane, Alaska, the society being the guests of the Alaska Gastineau Mining Co. The party was met at Thane at 4 p.m. and conducted through the shops, power-plant, and mills of the Gastineau company. After the sight-seeing trip, dinner was served in the mess-hall. Manager G. T. Jackson, president of the society, welcomed the members and guests. Papers, descriptive of the practice at the Gastineau mill, were read by E. V. Daveler, R. Hatch, H. E. Garlock, Fred Hodges, and Emil Gastongway. Officers were elected for the ensuing year, as follows: John Richards, president; Earl Daveler, vice-president; C. K. White, secretary; W. S. Pullen and C. E. Davidson were elected members of the executive committee.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—The Shattuck-Arizona is grading the mill-site on Denn ground and putting in concrete foundations. The mill will have a capacity of 400 tons per day. The Shattuck production of copper for October was 308,000 lb. and there is now every indication that the year's production will reach 13,000,000 lb.—The Denn Arizona is shipping a car of ore from development work every other day. This is chiefly from the 1300 and 1400-ft. levels.—Henry Valenzuela reports the discovery of hübnerite ore on his claims 13 miles south-east of Benson, near the American Tungsten Co. property.

Bisbee, November 23.

### GILA COUNTY

(Special Correspondence.)—The production of the Superior-Boston has reached 80 tons of ore per day. Recent developments on the 1000-ft. level continue favorable. Driving has been extended east for 80 ft. in copper glance ore that assays 8 to 11% copper. It is proposed to develop this ore on the 1200 and 1400-ft. levels.

Globe, November 22.

### MOHAVE COUNTY

(Special Correspondence.)—The first shipment of concentrate from the flotation-plant of the Washington Arizona has been made. The adit is in 1000 ft. and the shaft is being sunk from the 100 to the 250-ft. level.—Sinking has commenced in the Gold Ore shaft; the equipment is electrically driven.—Some rich ore is being taken from the 150-ft. level of the New Mohawk.—The development at the Hackberry mine has opened up ore to the value of \$3,000,000. F. W. Sherman has been engaged to design and erect a 300-ton mill. For a number of months the Hackberry has been shipping high-grade ore.—The United Eastern main shaft is almost complete, it being down 1060 ft. The lowest level will be 1090 ft. deep. The company has declared a 5c. dividend per share for November. The ten months of operation have yielded gross returns of \$1,512,679; total net profits were \$971,359, of which \$340,000 has been distributed in dividends. The Keystone mill is operating on dump ore. The Tom Reed production for October was 7500 tons of ore averaging \$8.04 per ton, the

break-down of the mill curtailing production for about 10 days.—The Middle Golconda is now shipping silver ore.

Kingman, November 24.

### PIMA COUNTY

(Special Correspondence.)—Belmont group of claims, in the San Xavier district, has been taken over by the Reineger-Freeman Mining Co. The erection of a mill at an early date is planned. The New Cornelia's production of copper for October was 3,628,800 pounds.

Tucson, November 17.

### PINAL COUNTY

(Special Correspondence.)—The cross-cut on the 300-ft. level of the Queen Creek Copper Co. has exposed a 20-ft. vein of copper ore that assays 14% copper. The company has closed a contract to drive a 300-ft. adit in a claim which has an excellent showing of silver ore, 2000 ft. from the shaft.—The new vertical shaft of the Arizona Coronado Copper Co. has cut the orebody at 128 ft. in depth. The orebody is 13 ft. wide and consists mainly of copper glance. Driving east and west for a distance of 208 ft. has opened up ore all the way.

Florence, November 23.

### YAVAPAI COUNTY

(Special Correspondence.)—The existing contract for hoisting all Jerome Verde ore in the Edith shaft of the United Verde Extension ceases on December 23. A new contract is being arranged by which the ore from the main top orebody will be trammed through the United Verde Extension to the Columbia shaft of the Jerome Verde.—The Black Canyon Mines Co. in the Turkey Creek district will erect a 200-ton flotation plant.—The Big Ledge Copper Co., which recently took over the Great Western smelter, has arranged to add two new converters and a reverberatory furnace, and to handle custom ores. With the new additions it is expected that the capacity of the smelter will be 800 to 1000 tons of ore per day.—It is reported that a recent strike in the Nevada mine of the Groom Creek district has opened up 14 inches of 800-oz. silver ore.—The Garford Syndicate, which in the early part of the year acquired the Copper Hill group in Copper Basin, has taken over the Robinson mines under a bond agreement. Recent development has opened up a considerable tonnage of zinc, lead, and copper ore.—The Arizona-Binghamton Co. has cross-cut 31 ft. of high-grade copper ore on the 600-ft. level. This ore for the most part is rich enough to ship.—The Patton Copper mine, four miles east of Mayer, has been taken over by the newly organized Rio Tonto Copper Mining Co.—The Copper Mountain Mines Co. is re-timbering one of the old shafts of the old Stoddard mine, and a gas hoist has been erected.—A two-foot vein of diorite schist, well mineralized with chalcopyrite, has been followed a distance of 30 ft. in the east drift from the Gorge adit of the Green Monster. This ore is said to run 8 to 10% copper.

The following appears in the issue of November 17: 'Operations at the United Verde Extension are proceeding rapidly. One blast-furnace of the new smelter will be blow-in next month.' An error was made in transcribing the notes; the sentence should have read: 'One blast-furnace will be blown-in next March.'

## CALIFORNIA

## AMADOR COUNTY

(Special Correspondence.)—After several months' work in enlarging the Old Eureka shaft below the 1600-ft. station to conform to the size of the shaft above that point, the bottom, 2065 ft., has been reached. A small opening served the purpose of the former management in prospecting to this depth and it has been a tedious task to remove the refuse from this narrow shaft, widen the opening for more than 400 ft., and timber it throughout. The three compartments are now in use from collar to bottom and sufficient work has been done around the 2000-ft. station to justify active development work there. Some prospecting will be done on the ore now exposed before continuing the shaft to greater depth. Large supplies of timber and lumber are being delivered.—During the last week, some ore of good grade has been developed in the stopes above the 3350-ft. level of Central Eureka mine. Assays of this range from \$4 to \$50 per ton; much of it shows free gold. Thirty of the forty stamps in the mill are in operation on ore from the 2540, 2690, 3350, and 3425-ft. levels. Shortage of labor accounts for the mill running under capacity.—Prospecting continues at the South Keystone Consolidated mines near Amador City. This property, which adjoins the South Spring Hill property, is being worked through the North Star shaft. Sutter Creek, November 22.

## ELDORADO COUNTY

(Special Correspondence.)—The Breala copper mine, situated one mile west of Breala, will begin shipping copper ore shortly. The manager, Victor E. Bonnefoy, states that at the 70-ft. level, in an old drift, he has opened a vein of sulphide copper ore that is fully 18 ft. wide; an average sample of the ore across the vein gave assay returns of 4.5% copper, \$2.53 gold, and \$1.11 silver.

The old 65-ft. shaft on the copper mine at Missouri Flat, in section 15,  $4\frac{1}{2}$  miles west of Placerville, has been unwatered. The manager states that the workmen have found in the old workings a vein about  $1\frac{1}{2}$  ft. wide which contains chalcopryite and bornite ore that runs 55% copper. After the orebody is further developed the owners intend to erect a mill. Placerville, November 16.

(Special Correspondence.)—Frank Dittmar and W. Pittenger have examined the Livingston property at Fairplay, in the interest of Montana capital. It is owned by Mrs. A. L. Livingston of Oakland, and was formerly worked profitably, being closed on the death of the present owner's husband.—Suit involving title to the Salmon Falls property has been filed in the Superior Court. Seven plaintiffs and seven defendants are named.

Placerville, November 27.

## NEVADA COUNTY

(Special Correspondence.)—Under management of H. Gerdtz, San Francisco people have placed the Blue Lead mine, at You Bet, in shape for extensive operations. A restraining dam and sluices have been erected in Missouri canyon. An abundant water supply is available and hydraulicking will start in a few days. Some of the gravel is excessively hard and will be blasted before monitors are brought to play on it.—The mill of the Golden Center Co. is again running on good ore from the 700-ft. level, and deeper work is being resumed as rapidly as unwatering of the shaft progresses. It is believed that the pumping plant is now sufficiently large to effectively handle all water, and the management expects to continue deep mining throughout the rainy season.—A deposit of graphite has been uncovered on the Black Quartz mine, near Washington, owned by C. S. Waite and H. N. Rawson. The deposit is four to six feet wide, and assays about 26% carbon.

Grass Valley, November 26.

## SHASTA COUNTY

(Special Correspondence.)—The Greenhorn mine near Tower House has just made a shipment of 50 tons of copper ore to the smelter at Kennett, as a test run.

Redding, November 30.

The Afterthought mine and flotation plant were closed down November 30 on telegraphic orders from the company's headquarters at St. Louis. One hundred and fifty men are laid off. Only a small crew will be kept at experimental work through the winter. The shut-down is due in part of the winter weather and in part to the returns from the oil-flotation plant. J. T. Robertson, general manager for the company, speaking of the oil-flotation plant, said: "The plant has not proved as satisfactory as hoped for, but it is confidently expected that the metallurgical problem will be solved by the experiments to be carried on this winter." The oil-flotation process has proved

PART OF CALIFORNIA

successful in other copper mines, but at the Afterthought the problem is a little different from that encountered elsewhere. The copper ore is heavily charged with zinc, making it impossible to smelt by the ordinary blast-furnace process. In the oil-flotation plant zinc and copper concentrates were recovered separately, and carload shipments were made to reduction works at Tacoma for copper and in Oklahoma for zinc. The Afterthought company has spent over \$250,000 on improvements this season. Ingot, which had been dead ever since the mine and smelter shut-down on January 1, 1908, again became a lively mining camp. Mr. Robertson predicts that the mine and plant will start up in the spring. In the meantime this thrifty town will be depopulated, for there is nothing but the mine and flotation plant to keep it going.

## TRINITY COUNTY

(Special Correspondence.)—The Jennings Gold Mining Co. has erected a 250-hp. motor on its claim five miles up Trinity river from Lewiston. The motor will pump water into a

reservoir on the hillside, where sufficient pressure will be given to operate a hydraulic giant near the river. Twelve men are employed under Fred. Dorman.—At the Balew mine near Lewiston two small giants will be operated all winter—one on gravel, the other on the dump. V. P. Demars is superintendent.

The Pacific Gold Dredging Co. has dismantled its dredge, moved it from Morrison gulch, and set it up at the mouth of Coffee creek.

Lewiston, December 1.

## COLORADO

### BOULDER COUNTY

(Special Correspondence.)—The old Smuggler mine, north of Jamestown, has been taken over by Denver people and capitalized at \$1,000,000. The Smuggler comprises six lode claims, on which considerable development has been done. Its past record gives it a high rank among the best properties of the district. W. E. Scott, of Gilpin county, has been given the management.—The Mitchell Bros. and T. W. Grouch of Lakewood, who have leased the Corkscrew No. 2 on one of the Primos company's properties, have been shipping tungsten ore, and will continue operations during the winter.—The Golden Age mine above Springdale has been taken over by Barnhill & Son and Salt Lake associates. Thomas Collins is superintendent. The mine will be re-opened and the old dump will be treated by a new process.—The old Longfellow mine, north of Jamestown, which was a heavy producer in the early days and which has been re-opened recently, has been making steady shipments of high-grade silver ore. It will be tapped at depth by an adit, which will be started this week by the owners, William Brown and associates.—The Smuggler Oil & Mining Co., in addition to its interest in the Smuggler mining property at Jamestown, will operate wells in the Brannon field north of Douglas, Wyoming. W. G. Bigelow of Denver is president, and John Rockwell secretary and treasurer.—The activity in mining at Caribou still continues. The recent new strike has ore that runs \$1700 in silver and lead. Many properties are producing heavily, and steady shipments from this old-time camp are going on.

Eldora, November 20.

### SAN JUAN COUNTY

(Special Correspondence.)—The Sunnyside Mining & Milling Co., a subsidiary of the United States Smelting, Refining & Mining Co., has its new 500-ton mill at Eureka under roof. A new aerial tramway from the mine to the mill is also under construction. About 150 tons per day is being treated in the old Sunnyside mill, where an excellent zinc-lead separation is being made by preferential flotation. Sodium manganate, manufactured at the plant from rhodonite, is used as a flotation reagent. The cascade flotation machines, which replaced the Hyde machines, have been discarded in favor of Minerals Separation apparatus. The Huff electrostatic plant has been dismantled.

The Genessee-Vanderbilt, Yankee Girl, and other properties near Red Mountain, which were recently under lease to James M. Hyde, have been taken over by the Red Mountain Mines Co., a subsidiary of the Mary Murphy Mines Co. Work is being done through the Genessee adit and the old steam compressor there is being used until a new electric-driven compressor can be erected. The equipment at the Joker adit is being overhauled preparatory to starting work there. The operations are being directed by George C. Collins of Denver, with Warren C. Prosser, a local engineer, as superintendent.—A fine body of shipping ore has recently been developed in the Lackawana. An aerial tramway is being built from the mine to the Silverton Northern track, a short distance above town.—The Hamlet is shut-down while some changes are made in the mill. It is expected that operations will be

resumed before the first of the year.—The Peerless San Juan mill has been undergoing extensive repairs and is expected to start soon.—The Iowa-Tiger, Pride of the West, Mayflower, Highland Mary, and Gold King are all shipping regularly. The Trilby has a small shift engaged in sinking a shaft.—It has been an unusually open autumn. There is, as yet, hardly any snow on the ground.

Silverton, November 23.

A syndicate composed of Isaac Untermyer, Willard P. Ward, and W. L. Fleming has arranged to underwrite 200,000 shares of the stock of the Vernon Mining Co. for the purpose of increasing the capacity of the mill to 120 tons per day which is estimated to give the company net earnings of about \$1000 per day at the present prices of metals. The company is capitalized for 1,000,000 shares with a par value of \$1 per share. The mine has been partly opened to a depth of 300 ft., which is still above the water-level; it is said to show 30,000 tons of ore with an average value of \$16 per ton in gold, silver, and copper. The property covers 450 acres and contains three veins, one of which is the Mogul vein on which is the well-known Sunnyside mine, recently purchased by the United States Smelting, Refining & Mining Co., at a price reported to be \$7,000,000.

## IDAHO

### SHOSHONE COUNTY

A dividend of 50c. per share has been declared by the Big Creek Leasing Co. at Kellogg, and was paid December 3. The disbursement is \$2500. This dividend is the fourth, the first having been made about six months ago. It will raise the total of distribution to \$10,000. The profits are derived from ore produced on a section of the Yankee Boy mine on Big creek, east of Kellogg.—At a meeting of the Columbia section of the A. I. M. E. held at Kellogg, S. S. Fowler of Blondel, B. C. was chosen section chairman for the coming year; J. C. Haas of Spokane was elected vice-chairman, and L. K. Armstrong of Spokane was re-elected secretary. The next session of the section will be held at Spokane during the mining convention in February.—The regular monthly dividend of 3c. per share was paid on December 5 by the Caledonia Mining Co., operating in the Coeur d'Alene district. The disbursement was \$78,150, bringing payments for the current year to \$859,650, and the grand total to \$2,835,241.—A dividend of 50c. per share has been declared by the Consolidated Interstate-Callahan Mining Co. of Wallace, to be paid on January 2. The amount is \$232,495, which will bring the total payments of the company to \$6,500,860. The last dividend was for \$1 per share, disbursed on June 30. The dividend for the quarter ended September 30 was passed so that a surplus might be built for war tax requirements. It is assumed that the reduction to 50c. per share was made with the same end in view.

The meeting of the Idaho Mining Association assembled at Wallace, Idaho, November 24, for the purpose of considering business, political, and industrial matters, affecting the mining industry of the State of Idaho, and incidentally of the Nation, connected therewith, refers to the recent War Income Tax Law enacted by Congress and declares that the mining industry should bear its just and equitable proportion of all expenses of government, federal, state, and municipal, under which it is protected; and that it should and does stand ready to meet all taxes imposed upon it by constituted authority, and particularly those taxes imposed by the War Revenue Law passed by the Federal government, and it willingly offers to support all War burdens imposed by the Government to as great an extent as those that may be imposed upon any other industry, even to the limit of the confiscation of all its property, if that be necessary, to bring about a successful termination of the War now being so justly and patriotically prosecuted by our country for humanity.

But this association declares that all should bear the War Tax, levied upon all alike, under a fixed principle, without discrimination, to the end that all shall be equably taxed.

## MONTANA

### LEWIS AND CLARK COUNTY

(Special Correspondence.)—Low-grade manganese ore is being concentrated at the plant of the Montana Testing & Engineering Co. at Helena. The ore comes from Philipsburg, west of the range, and is below 35%. Arrangements have been perfected to receive the same character of ore from W. A. Clark's mines in Butte. Several carloads of concentrate have already been sent to iron works in Pennsylvania.—The ball-mill at the Porphyry Dike has been completed, and the pipeline and pumping stations for running the tailing from the mill to the Boulder water-shed are in place. The mine is closed and may not be operated before next spring owing to a shortage of water.—The Montana Peerless Co. has taken over the old Peerless Jennie property and is preparing to develop it. The mine has produced no ore for years, but shipments from near the surface in the early '70s ran up to \$1000 per ton. The ore was shipped to Swansea in Wales for smelting.—The Helena Mining Bureau is sending out two carloads per week from the Helena mine.—The Shannon mine, of the Barnes-King Co., is producing well. The total production for all its mines amount to \$100,000 per month.—The Marysville Gold Syndicate has arranged to mill 30 tons per day from the Blue Bird-Hickey adit.—There is a probability that the Thomas Cruse Development Co. and the Scratch Gravel Gold Co. may consolidate. They have been operating adjoining properties in Scratch Gravel hills.

Helena, November 27.

## NEVADA

### ESMERALDA COUNTY

(Special Correspondence.)—The Goldfield Consolidated Co. has taken a bond and option on the Curtz Consolidated group of mines near Markleeville, California, for a reputed price of \$500,000. The orebodies are large and contain gold, silver, and copper. The Curtz Consolidated Co. has been working for several years and a large ore-reserve is stated to be exposed. The Consolidated is also developing the Surcease gold property near Oroville, California, and is examining gold properties in California, Nevada, South America, and other fields. Small profits are attending operation of the Goldfield Consolidated mines, due partly to difficulty in disposing of flotation concentrate. Large bodies of low-grade copper-gold ore are being developed in the lower levels of the Laguna, Grizzly Bear, Clermont, and other properties. The Aurora Consolidated is reported to be earning a small monthly profit.—Goldfield companies are steadily extending the use of the leasing system. Numerous blocks of ground in the Consolidated, Florence, Sandstorm-Kendall, and other mines are being worked by lessees with encouraging results, but as work advances it is evident that the rich deposits near surface were largely exhausted by the companies. The hope of the future is based on possibilities attending deeper work in the Atlanta and Jumbo Extension, where promising discoveries have been made within the shale. At the Atlanta the winze is nearing the 1900-ft. point, where a cross-cut will be extended to seek the Atlanta vein, which yielded high-grade ore on the 1750-ft. level. The new vein recently intersected at a depth of 1830 ft. carries little profitable ore and is apparently an off-shoot from the Atlanta vein. The winze is expected to enter the alaskite-shale contact at an approximate depth of 2000 feet.

The Mason Valley Co. hopes to place the second furnace of its Thompson smelter in operation before the end of December. The first furnace is operated largely on ore from the Mason Valley, Bluestone, and Nevada-Douglas mines, and a heavy

tonnage from the Nevada-Douglas and several properties in the Luning district is assured for the second unit.—The Nevada-Douglas reports net monthly earnings in excess of \$20,000.—More than 20 companies are shipping from the Luning field and others will start production as soon as the Thompson smelter is ready for their ore.—The June Bug Co., of San Francisco, is developing the Scorpion group of silver-lead claims near Reservation and expects to make a shipment soon. The Reservation Hill Co. has a shipment of high-grade silver-lead ore ready.—The Sebastopol, Pack Saddle, Mountain View, and other companies in the Reservation field are active.

Goldfield, November 25.

### LINCOLN COUNTY

(Special Correspondence.)—The Springfield Mining Co. has re-timbered the shaft of the Ely Valley to the 400-ft. level. On the 130-ft. level good ore is showing; a shipment of gold-silver ore will be made soon. Below the 450-ft. point a vein containing copper has been prospected to a limited extent. M. Reel is manager.—The Virginia-Louise Co. is preparing for operations along broader lines. A large hoisting engine has been acquired and a head-frame, bunkhouse, and other structures are being built. Development has been in progress upward of a year and profitable ore has been exposed.—The Prince Consolidated is shipping 40 tons of ore per day.—The Davidson Mining Co. controlled by the Prince Consolidated, is increasing operations on the Division group. Cross-cuts are being extended from the 416-ft. incline and 150-ft. vertical shafts; the orebody has been cut at several points, showing a width of 70 ft. Ore is of the same grade as exposed in the Prince Consolidated and Virginia-Louise.

Pioche, November 25.

### MINERAL COUNTY

(Special Correspondence.)—At the Congress mine a big vein is being developed; it is 26 ft. wide and averages 3% copper, while the soft monzonite of the hanging wall will go from 1.5 to 2% of that metal for a width of 60 ft. The whole 86 ft. should pay well if treated on the ground.—The Luning Idaho did not make the expected shipment this week as the Thompson smelter failed to blow-in its second unit, on account of a shortage of coke. Shipping-ore is coming from the Conte winze; the Stockham adit is now in 150 ft.—The R. B. Todd Co. is sinking on the Abe Lincoln claim, from which a shipment was recently made; the shaft is in ore of the average grade.—Two more leases have been let on the Anderson group of the Pilot company. The company is sending out a large tonnage under the new contract of the ore buyer, which permits the marketing of a lower grade of ore at a profit.—A carload of ore that will average 8% copper went out from the Siri shaft of the Wedge mine this week. A contract was let for an additional 100 ft. in the No. 2 adit. The proposed merger of the Wedge and some good surrounding mines has not been consummated as yet, but it is believed that the deal will go through.—The Kirchen Mines Co. continues to ship steadily from its St. Patrick mine, the ore of late running 9% copper. What is known as the 'picture stope' on the lower level is attracting much attention on account of the beautiful coloring of the high-grade ore.—E. C. Watson has returned from an extended trip and has taken a lease on the Anderson group of the Pilot company.

Luning, November 21.

(Special Correspondence.)—The east drift on the 290-ft. level of the Wall Street mine at Luning is now out 30 ft. and for that distance two feet of the ore averages 24% copper. The other workings are also looking unusually well, and Mr. Gerhardt, the manager, is making arrangements to handle a much increased production.—E. H. Wedekind, at one time manager of the Balaklala mine and smelter in Shasta county,

California, has been engaged as consulting engineer for the Wedge Copper Co. From a preliminary examination he expresses himself as well pleased with the Wedge and says that work already done has opened up two good ore-shoots from which ore of excellent grade is being produced.—The Kirchen Mines Co. has opened a three-foot silicious vein in the monzonite, separate from the big vein on the lime-monzonite contact, which gave 6% copper as the net return of two carloads shipped.—The Pilot Copper Co. has found a rich deposit away from the big vein on the contact. This is in the lime hanging wall and the return from one carload was 8% copper, 4 oz. silver, and 0.04 oz. gold.—The Luning Idaho is saving ore from a vein that has been proved for a length of 4500 ft. within the company's property lines.—J. C. Brumblay, Reno representative of the United States Smelting company, has been looking over the Luning district for the past week.

Luning, November 29.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—The Oaks Co. has taken over the active operation of the Pacific mine. The company is largely interested in the ownership of the mine, and plans extensive development. Until the aerial tramway is again in commission burros or auto trucks will be used in moving ore to mill. The Central group is producing daily and the recent developments on Maud S. and other mines of the Oaks Co. are increasing the ore-reserves.—Thirty 100-lb. bars are now being shipped per month by the Mogollon Mines Co. besides several tons of high-grade concentrate. Both mill and mine are working to capacity.—The firm of Cleaveland & Weatherhead, owners of the Deadwood Sunburst mines and mill, has merged its partnership into the Deadwood Mining Company. The ownership remains the same and plans are being made to open up the property in the near future. The mill is modern and arrangements will be made to enlarge the mine equipment.

Mogollon, November 27.

## OREGON

### JACKSON COUNTY

(Special Correspondence.)—Mine operators in this district anticipated a relief from the shortage of help as soon as the miners working in the lumber camps returned for the winter, but the new supply is insufficient to meet the loss of the miners of the draft age who are enlisting in the service of their own choice before the second draft is called. The Blue Ledge mine lost seven men in one day last week.—H. H. Leonard, lessee of the Bowden mine, three miles south of Gold Hill, is now operating in the 120-ft. level on a 3-ft. vein of rich ore. He also has taken a lease on the Yellow Jacket, an adjoining property, owned by Thomas Hagen, who is now his superintendent.—W. A. Douglas, a local mine operator, has taken a lease on the G. Danielson quartz gold mine on Galls creek, three miles west of Gold Hill. This property is on old producer, but has been idle for a number of years. The lessee will re-open the old drift and extend it on the vein into adjoining property owned by himself and Thomas Dungey.—R. M. Wilson is equipping and will operate the Nellie Wright mine and mill, three miles south of Gold Hill, which has been closed down the past 90 days.—The Manganese Metal Co. of Tacoma has received three cars of machinery for its manganese property in the Lake Creek district, 20 miles east of Gold Hill. Shipments will be made from Eagle Point.

Gold Hill, November 24.

## VIRGINIA

### LOUISA COUNTY

The Virginia Lead & Zinc Corporation has completed its

standard-gage railroad from Sulphur Mine in Louisa county to Valzinco in Spotsylvania county, a distance of 10 miles. It is constructed in accordance with specifications of the Chesapeake & Ohio railway, with which it connects at Mineral, Virginia, as a first-class branch-line, adapted to the heaviest rolling-stock. The corporation is operating the Valcooper zinc mine and mill on the line of the new road, three miles north of Sulphur Mine. Its principal mines, however, are at Valzinco, where a large tonnage of high-grade zinc-lead ore has been developed on a wide vein which has been opened up to a depth of 350 ft. for a length of over 1200 ft. on the strike. Other veins, equally promising, have been prospected. The completion of the railroad will be signalized by extensive development. The company bids fair to become an important factor in the Eastern zinc-situation. The president is Berkeley Williams of Richmond, and the manager is J. H. Batcheller. The mine offices are at Mineral and at Jones Store, Virginia.

## WASHINGTON

### STEVENS COUNTY

Renewed interest in Deer Trail camp has been aroused by the discovery of valuable ore, missed by pioneer operators a quarter of a century ago, in the old Queen mine, under operation by the Silver Basin Mining Co., according to Charles H. Goodsell, deputy U. S. mineral surveyor. "The body has a width of four feet and a content of 200 oz. of silver per ton," said Mr. Goodsell. "It was found by breaking into a false wall, alongside of which a drift had been run 200 ft. on the 125-ft. level many years ago. Residents are enthusiastic over the discovery. High-grade copper ore is being moved every day from the Turk mine and the camp seems to be coming back, assisted by higher levels for the metals. Other old properties await the touch of the developer."—Mr. Jarvis, the receiver, has sold the Copper King property at Chewelah, to H. S. Wales of the Northwest Magnesite Co. for \$75,000. It is said the debts of the Copper King aggregate about \$45,000, which will leave a considerable amount for the stockholders. Mr. Wales has been connected with development of the magnesite industry in this county from the first operations. The Copper King lies beyond the United Copper property and is well developed. It is understood Mr. Wales will make arrangements for the development of the property.

## CANADA

### BRITISH COLUMBIA

The strike of employees at the smelter of the Consolidated Mining & Smelting Co., Trail, B. C., has resulted in a suspension of operations at several large and small properties in British Columbia and a reduction in the number of employees at others. Ore is being accumulated at some mines where the storage capacity is sufficient.—Employees of the Trail plant struck for an eight-hour day. About 400 were working on a nine-hour basis, according to estimates. The number of smelter employees affected is 1500. The company has given notice that it will receive no more ore at present. The suspension interrupts the smelting of 8000 to 10,000 tons of ore per week. The first week of this month, in which the receipts were 8996 tons, may be taken as an illustration. The names of the mines and their contribution in that period were as follows: Blue Bell 183, Centre Star 856, Couvrapee 69, Delphia 11, Emerald 40, Emma 615, Electric Point 350, Gem 6, Galena Farm 50, Iron Mask 32, Jessie Blue Bell 3, Josie 353, Knob Hill 151, Lucky Jim 134, Lucky Thought 54, Le Roi 2490, Mandy 29, Metaline Falls 84, Payne 21, Quilp 536, United Copper 144, Rambler 72, P. Schufer, 7, Slocan Star 40, Surprise 88, Standard 79, Sullivan 2224, Triune 28, Tip Top 137, P. Higgins 7, Van Roi 103 tons. When relief may be expected is uncertain, both employer and employee having taken firm stands in the controversy. More than half the ore shipped to Trail is

from mines owned by the Consolidated. The smelting company has lead for three months at the recent rate of demand, according to an estimate made early in the fall. Its coke is being diverted to the Granby Consolidated Mining, Smelting & Power Co. The number of miners affected is large. It approaches that at the smelter.

MAP SHOWING POSITION OF TRAIL

The Granby Consolidated Mining, Smelting & Power Co. produced 3,259,974 lb. of copper in October. The Anyox plant produced 2,391,800 lb. of this quantity and Grand Forks 368,174 lb. A comparison of production shows a decrease of 800,000 lb. in October from November 1916, and a decrease of more than 500,000 lb. from August. The decrease at Anyox has been in recent months. The reduction results from changes and improvements being made in the Anyox plant. Two converters are idle, pending the completion of changes, and a steam-driven power plant is being built. The surplus matte is being shipped to Grand Forks for refining. This increases the credit of the latter plant while reducing that of Anyox. The steam plant is expected to make possible the operation of the smelter at the average capacity, or near it, in the winter months, when there has been a reduction because of limited water-power.

The Grand Forks plant was idle in May and June 1916, because of a shortage of coke. Preparations for the erection of buildings for the men to be employed in the development of its recently acquired coal properties are being made by the Granby at Cassidy's landing, near Nanaimo, where its work and wharves will be centred.

## Montana Section A. I. M. E.

This section held its regular fall meeting on November 16, at the Silver Bow Club, Butte, when 68 members and guests attended the dinner and technical session. The programme included 'Notes on the St. Louis Meeting,' by C. W. Goodale, with discussion by J. H. Warner, Alexander Leggatt, N. B. Braly, and E. B. Young. 'Work of the War Minerals Committee,' by E. B. Young. 'The Manganese Situation,' by R. H. Sales. 'Fire-Proofing of Mine-Shafts,' by E. N. Norris, with discussion by Messrs. Berrien, Nighman, Braly, Daly, Dunshee, and Carrigan. 'Fire-Extinction by Hydraulic Filling,' by C. L. Berrien and C. E. Nighman. The meeting closed with interesting talks by B. B. Thayer and Spencer Miller, both members of the Naval Consulting Board, and Robert Sticht of Tasmania.

W. B. JEFFREY died at Los Angeles on October 29. At one time he was manager of the Pinos Altos and of the Avino mines, in Mexico. He was a capable and trustworthy engineer, of high character and engaging personality. One of his sons, R. H. Jeffrey, is now manager for the Mazapil Copper Company, at Saltillo, Mexico.

THE CANADIAN MINING INSTITUTE has moved to 503 Drummond Bdg., 511 St. Catherine street, West, Montreal.

# PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

CHARLES BUTTERS is at Washington.

E. M. HAMILTON has returned from Pachuca, Mexico.

V. G. HILLS is examining mines at Chloride, Arizona.

J. W. MERCER visited Denver on his return to New York.

W. A. HUNTER was in San Francisco from Eclipse, California.

F. L. SIZER has moved his office to 1006 Hobart Bdg., San Francisco.

R. B. MCGINNIS has moved his office to Mills Bdg., San Francisco.

W. A. HUNTER, of Eclipse, Plumas county, was in town during the week.

J. H. MACKENZIE returned to San Francisco from Juneau, Alaska, last week.

D. C. JACKLING has returned to San Francisco from a periodical tour of inspection.

GERALD SHERMAN, manager of the Copper Queen, was in San Francisco during the week.

J. I. THOMAS, recently in the Afterthought mill, near Redding, has gone to Ely, Nevada.

O. H. REINHOLT, of San Diego, has been examining a manganese prospect in Lower California.

H. HUNTINGTON MILLER has been examining properties in the vicinity of Tucson, and is now in New York.

RUSH T. SILL, of Los Angeles, has just returned from a business trip to Mexico City and Pachuca, Mexico.

N. I. TRUSCHKOFF, mining engineer to the Bogoslovsk Mining & Trading Co., Petrograd, is in San Francisco.

G. J. STEELE, sergeant in the Military Police, has returned from France as instructor to the American army.

H. W. MACFARREN has been commissioned Captain in the 116th Engineers and is now on his way to France.

JAMES L. KEELYN, of Pasadena, has received a commission as Captain at the Training Camp of the Presidio, San Francisco.

J. W. WHITEHURST has received a commission in the U. S. R., having been in training at Fort Sheridan for the last three months.

F. W. DENTON, director and consulting engineer of the Copper Range interests, has gone to Boston, where he will reside during the winter.

C. H. COOPER, assistant superintendent of the Calumet & Hecla smelters at Hubbell, has been appointed a Captain in the Coast Artillery, U. S. R.

JOHN W. RICHARDS, formerly at Spokane, has been commissioned First Lieutenant in the National Army and is now at American Lake, Washington.

A. W. STEVENS is on his way to Nicaragua, having been appointed mine-superintendent of the Leonesa mine, for the Mina Leonesa, Ltd., of London.

W. G. FARNLACHER and FRANK J. HOENIGMANN have been commissioned First Lieutenants in the Infantry and are to go on active duty on December 15.

LOUIS GAY, for ten years foreman of the Mammoth mine near Kennett, has resigned and will live retired at Redding. RICHARD J. MINEAR succeeds him.

STILLMAN BATCHELOR, recently engineer for the Globe Mining Co., California, is now associated with CHESTER A. FULTON, mining engineer, at Havana, Cuba.

COREY C. BRAYTON and E. R. RICHARDS have temporarily closed their San Francisco offices in order to give more time to their operations at Midvale, Utah.

ARTHUR P. WAIT has resigned from the St. Louis Smelting & Refining Co., and has been engaged as metallurgist by the Missouri Metals Corporation, at Mine La Motte, Missouri.

# THE METAL MARKET

## METAL PRICES

San Francisco, December 4

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	16.00
Antimony (wholesale), cents per pound.....	15.25
Electrolytic copper, cents per pound.....	23.50
Pig-lead, cents per pound.....	6.50—7.50
Platinum, soft and hard metal, respectively, per ounce.....	\$105—113
Quicksilver, per flask of 75 lb.....	115
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	20

## ORE PRICES

San Francisco, December 4

Antimony, 45% metal, per unit.....	\$1.00
Chrome, 34 to 40%, free SiO <sub>2</sub> , limit 8%, f.o.b. California, per unit, according to grade.....	\$0.60—0.70
Chrome, 40% and over.....	\$0.70—0.85
Magnesite, crude, per ton.....	\$8.00—10.00
The magnesite market remains practically the same; considerable calcined and raw magnesite has been offered, but no business to amount to anything has been reported.	
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.	
Tungsten, 60% WO <sub>3</sub> , per unit.....	26.00
Molybdenite, per unit MoS <sub>2</sub> .....	\$40.00—45.00

## EASTERN METAL MARKET

(By wire from New York)

December 4.—Copper is unchanged and nominal at 23.50c. all week. Lead is quiet and steady at 6.50c. all week. Zinc is dull and easy at 8c. all week. Platinum sells at \$105 for soft metal and \$113 for hard.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Nov. ....	18.88	31.95	23.50
Dec. ....	20.67	32.89	....

The Government fixed price remains at 23½c. Electrolytic copper is quoted 25½c. per pound, figuring the 5% as arranged for the jobber's benefit, which, of course, is the only way to look at the question of price

fixing, as dealers and jobbers would not have the benefit of the 23½c. price before January.

Copper scrap is in excellent demand and bringing higher prices. There is a firm tone for brass scrap. The demand for heavy-lead scrap is excellent, the price being on a close parity with the virgin metal. The small quantity of tin scrap available is bringing fancy prices. Zinc scrap is not in demand.

## LEAD

Lead is quoted in cents per pound, New York delivery.

## TUNGSTEN

The fact that Europe is buying considerable ore in South America has had some influence on the market and prices for wolframite and other grades have advanced to \$25 to \$26, though scheelite is unchanged at \$26 per unit in 60% concentrate. Ferro-tungsten has been sold in small lots at \$3.25 per lb. of contained tungsten and this is the minimum quotation.

## MOLYBDENUM AND ANTIMONY

Molybdenite is unchanged and firm at \$2.15 to \$2.25 per lb. of MoS<sub>2</sub> in 90% material. There is nothing to report as to antimony ore.

Charles Hardy says: Fair quantities of concentrate have changed hands since my last report. European buyers are still in the South American market, especially in the Argentine and continue to pay high prices. Highest grade wolframite ranges from \$24 to \$26, the latter price having been obtained for the very highest grade, containing no impurities such as tin and copper. Considerable quantities of wolframite containing impurities have been sold at prices ranging from \$23 up according to grade. Scheelite remains firm at \$26. Most of the sellers, however, are holding for higher prices.

The molybdenite market remains steady at prices ranging from \$2.15 to \$2.25 per pound MoS<sub>2</sub> contained, basis 90%.

The antimony market has apparently raised one-half cent per pound to 14½c. duty paid, New York; shipment continues at 13½c. c.i.f. New York in bond. The above prices are all nominal.

The present schedule for manganese remains at \$1.20 per unit for high-grade ore.

The tin position has felt no relief, the price being on Straits tin at 80c. per pound. It was expected that some good might come from the new Government regulation as covered by the American Iron and Steel Institute, Bulletin No. 1, which was issued November 22, but the market has advanced rather than eased; 99% tin is offered at 66½c. cents.

The Trust price of lead remains at 6¼c. per pound, although sale of the first quarter lead has been made at 6¼c. New York.

Spelter prices are prompt New York. Prime Western ranges from 7½ to 8c. It is apparent that the Government is not going to fix a price for the present at any rate on prime Western spelter, the law of supply and demand being left to work out the situation.

Very little high-grade chrome ore has been offered and it is reported that the quantities of 42 to 45% is also very scarce. The market remains at 90c. per unit, quoted f.o.b. California shipping point.

# Eastern Metal Market

New York, November 28.

The markets are all inactive with two of the leading metals under Government control, or practically so, tin now following copper in this respect.

Copper is unchanged, with quotations nominal at the Government price.

Tin is scarce and nominally higher.

Lead is inactive but the tone is firm.

Zinc is dull but no weaker.

Antimony is a little stronger and higher.

Aluminum is dead and unchanged.

In the steel market there is an increasing demand from both Government and domestic consumers, with the latter buying for needs other than war necessities. There is no improvement in blast-furnace or steel-works operations, those at Youngstown being at not more than 50 to 75% of capacity, while at Pittsburgh the decline is less. It is expected that the situation in Russia will result in the release of locomotives and possibly cars to relieve the congestion in this country. The shortage in pig-iron is not relieved, and the fuel situation is unimproved, with the possibility that the Government may have to call on coke-producers to furnish coke to steel and iron-producers to keep them running so as to furnish steel ships, shells, and other war-equipment.

## COPPER

The situation has been somewhat cleared by an announcement last week determining the jobbers' position. It is now officially declared that small dealers may dispose of their holdings at a 5% profit for cash, with interest at 6% chargeable for time. This refers officially to the copper bought at the 23.50c. Government price, but, as no such metal is now obtainable from producers, it is inferred that metal now in jobbers' hands can be parted with on at least a 5% profit, or for any price that can be obtained. While the latter practice in many cases has been going on for some time, and while some small dealers have continuously refrained from selling, all are now offering their metal, and sales of small lots are going at 27 to 28c. per lb. After January 1, when metal bought at the Government price is delivered, it will sell at 24.675c. per lb., and no more in jobbing lots. While the present arrangement is a hardship to some, it is felt that ultimately it will result in the elimination of the speculator—a decided boon to the entire trade. In general the trade is strictly a regulated one. Your correspondent had an interview yesterday with a member of the Copper Producers' Committee. The whole situation was made clear. The Government's needs come first absolutely. Its orders for copper will mount into large figures, though specifications on these orders as yet are not coming in very fast. Consumers having Government work are awarded metal first, even though they have no copper on contract, in which case it is being delivered at the Government price of 23.50c., which we continue to quote as nominal. Such metal is, however, only for the consumer's own consumption. Copper is being delivered on old contracts at the original price for first-quarter delivery, even for use in commercial lines, but with the understanding that if the Government require the copper the contract will be cancelled or postponed. General satisfaction seems to prevail, and no one legitimately needing any copper seems to be without it. It is hoped, but not certain, that there will be enough copper to meet all needs, but some believe the supply will not be adequate.

## TIN

There have been two important features since my last letter, but no market. In fact the week has been an eventful one. First in importance is the official announcement that the

American Iron and Steel Institute will act for the War Industries Board so as to completely control the tin market. In its hands will be the distribution of all tin. To it all imports will be consigned. No one will be permitted to do any business until they have signed blanks strictly defining their rights. A pamphlet has been issued giving details. The arrangement is similar to the existing one by which the British Consul at New York regulates the trade. The new control, however, will be more stringent, as ultimately defined by the United States government. It is not yet effective, however, as some details are still to be worked out, but it is expected that it will be soon. The other feature of interest is the report, probably true but not confirmed by your correspondent at first hand, that the Government has commandeered all tin in bonded warehouses and probably in all others. When its own needs are satisfied the remaining metal will be released to its owners. From a market point of view there has been no market nor is one possible under present conditions. The spot-situation is no better. Attempts to buy spot Straits yesterday and Monday, and on last Thursday and Friday, at 80c. bid, and last Wednesday at 78.50c. bid, were without results. The market is, therefore, quoted nominally at 80c., New York. Some consumers are short of tin, and if they have Government work the Government can get it for them; but there is no incentive to buy tin. If one does buy it he may not get it, and if he does the Government may appropriate it with a possible loss to the buyer. The entire situation is at present unsettled. Arrivals to November 27, inclusive, have been 1310 tons, with 4100 tons reported afloat. The London market continues to advance, spot Straits yesterday being sold at £284 per ton, an advance in the week of £4½ per ton.

## LEAD

The market is devoid of interest or feature. Price-levels remain unaltered from those of last week, with the outside market at 6.50c., New York, and 6.37½c., St. Louis, and with the American Smelting & Refining Co. quoting 6.25c., New York. The tone of the market is firm and steady at these levels. Demand is of small proportions, and sales have been light. It is purely a drifting market. New developments must come to arouse interest. Consumers are well covered, and producers and dealers well filled with orders. Some imported lead from Mexico has been done at 6c., New York, in bond.

## ZINC

The market is still lifeless and without interest. It continues to drag along in an aimless way. There seems no factor operating to cause a demand, although galvanizers are said to have come into the market recently to a greater extent than for some time, but this does not mean much. The quotations are unchanged at 7.75c., St. Louis, or 8c., New York, for prime Western for early delivery, or even for delivery through January. These quotations are being shaded slightly by certain sellers whom some dealers characterize as 'weak sisters.' Nothing is heard of further Government shell-orders so far as orders for zinc are concerned, and very little is being said about the results of the new Zinc Committee's negotiations with the Government.

## ANTIMONY

There has been a little better demand which has rendered the market slightly stronger, and the quotation now stands at 4 to 14.50c. per lb., New York, duty paid, for early delivery, for the brands available, mostly Chinese and Japanese.

## ALUMINUM

The market is without interest, with No. 1 virgin metal, 98 to 99% pure, unchanged at 36 to 38c. per lb., New York.

# INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

## DENVER HYDRO AIR-COMPRESSOR

In this system the tank at the left is filled with water carrying a brass inverted cup up to its ground seat, which closes the ports through a piston, thus stopping further passage, and causing the water to force the piston upward. A rod passes down through the tank at the bottom, having a suitable nut at its lower end, engaging a bifurcated bell-crank that reverses the auxiliary valve in the centre. This admits water under

TESTING HYDRO AIR-COMPRESSOR

pressure at the opposite end of the admission-valve. That opens the exhaust to the opposite end. Thus the admission-valve is carried to the opposite end of the cylinder, opening the large discharge valve at the tank just filled and closing that to the tank to which water is being admitted. When the tank has filled it will float the cup to its seat, when the water will raise the piston and reverse the operation of the compressor and thus continue the automatic operation unless the compressor makes air faster than it is being used, when it will carry the air-pressure to the water-pressure and stop until the air-pressure has been reduced, when the compressor will start again. Where one has mountain water under heads of from 200 to 350 ft., this is the cheapest, and by far the best, method for converting the dynamic power of the water into compressed air direct without the intervention of wheels, shaftings, etc., that are necessary to run a power-driven compressor in the usual way, with the consequent loss of power. The Denver 'Hydro' is so simple that one does not need to be technically informed in the practice of compressing air to

see the distinct advantages it has over the old methods for converting hydrostatic into pneumatic power, as it automatically and directly converts the water-pressure into air-pressure, eliminating the three great losses suffered by the old method: (a) From loss at the water-wheel; (b) from piston over-travel, friction, vacuum, and heat of the compressor; (c) the intermittent load-loss of the air-compressor. These three losses will total not less than 60% on the best modern equipment when new, and each day they have been used will deduct from their efficiency. By this means air is taken into a water-cooled compression-chamber and delivered into the receiver at isothermal temperature; nothing is lost from over-travel, that is, from air leaking back over the piston while pumping, nor from friction or the intermittent load, as air is inspired into the compression-chamber while there is no resistance-load, thereby increasing the volume of air delivery.

## A BIG SHIPMENT OF RUBBER BELTING

MADE IN THE U.S.A.

The accompanying illustration shows a single order for rubber belting shipped from Boston, Massachusetts, to the Burma Mining Corporation, Tawng Peng, via Rangoon. The shipment, weighing 22 tons, will have traveled about 18,000 miles, or nearly three-fourths of the way around the earth before it finally reaches its destination. The belting is to be used in the Bawdwin mines for conveying and elevating the ore in the new mills. The Burma mines are considered one of the richest zinc, lead, and silver mines in the world. Indications show that they were worked by the Chinese from the 15th century and abandoned about 1868. Increase in the volume of water in the workings was the cause of abandonment. Nevertheless, during the long occupancy of the Chinese it is estimated that more than a million tons of rock was removed. The company operating the mines is now building a modern plant which treats 1500 tons of ore per day. Belt orders

BOSTON BELTING EN ROUTE FOR INDIA

of this magnitude, comprising all the belt equipment for these mines, are typical of the way in which American manufacturers are getting the world's business. War material

is not wholly responsible for the business boom. In pre-war times England no doubt would absorb the majority of the trade of southern Asia, but far-seeing American manufacturers are invading new territory that heretofore was entirely out of reach. The belting shown in the illustration was made by the oldest rubber concern in existence, the Boston Belting Company.

## WIDER USE OF MOTOR-TRUCKS

"Extensive motorization of the delivery and haulage departments of many business concerns, made necessary by the increasing scarcity of horses, is now considered practical because of the wonderful development of the four-wheel drive type of truck during the last few years," says H. M. Lee, president and general manager of the Duplex Truck Co. "The Government has awakened to the wonderful possibilities offered by four-wheel drive trucks and thousands of these motor vehicles will play important rôles during the War. George W. Dunham, president of the Society of Automobile Engineers and civilian member of the committee having charge of motorizing the Field Artillery of the Army, says a large number of four-wheel drive trucks will be provided for the handling of American ammunition. In an address at Buffalo recently, Mr. Dunham said: 'The four-wheel drive vehicles are suitable for operation over rough grounds and under conditions where the ordinary vehicle of the road type would find it difficult to secure the necessary foothold.' We find that many industries are now enabled to motorize for the first time with our four-wheel drive truck. This is especially true in lumber and mining regions where horse, mule, and ox-teams have been the only practical means of transporting the products to market."

## TONS OF STONE BROKEN PER POUND OF EXPLOSIVE

The following records of blasts made in different parts of the country may be taken as typical of modern practice. It will be seen that the average is from four to six tons of stone broken per pound of explosive when blasting with deep bore-holes, such as those made with the churn-drill.

A blast in a limestone quarry in Tennessee, where the stone was being produced for ballast, consisted of 16 bore-holes, 5½ in. diam. each, with an average depth of 75 ft. The holes were spaced 18 ft. apart, having an average face-burden of 22 ft., and 3750 lb. of 60% and 3700 lb. of 40% low-freezing dynamite were used in the blast, producing 5.7 tons per pound of explosive. A little higher result is noted in a blast at a cement-rock quarry in Pennsylvania, where 14 bore-holes, 5½ in. diam., and 86 ft. deep on an average, placed 18 ft. apart, with a face-burden of 30 ft., were charged with 4850 lb. of 60% and 3250 lb. of 40% dynamite, and yielded 55,000 tons of broken rock, or 6.8 tons per pound of explosive. At a Kentucky limestone quarry, producing stone for ballast, a blast of 9 bore-holes 50 ft. deep, spaced 18 ft. apart, and 25 ft. back from the edge of the bench, loaded with 3250 lb. of 40% dynamite, produced 16,200 tons, or 5 tons of rock per pound of explosive. Again, in an Oklahoma quarry, where the stone was to be used for railroad ballast, 8 bore-holes 95 ft. deep, with an average space between holes of 28 ft., and an average face-burden of 38 ft., were charged with 2200 lb. blasting gelatine, 3350 lb. of 60%, and 1250 lb. of 40% dynamite. A total of 6800 lb. of powder in this case produced 62,000 tons, or 9 tons per pound of explosive. Moreover, this blast was badly balanced, necessitating the use of very strong explosive at the bottom, and the cost per ton was just as high or higher than a balanced blast.

Another example is that of an iron ore where 26 holes, 5½ in. diam., averaging 84 ft. deep, spaced 15 by 15 ft. apart, with the holes triple-loaded and fired with cordeau and one electric blasting cap, charged with 8500 lb. 40% dynamite, produced

50,000 tons of ore, or 5 tons per pound of explosive. In a cement-rock quarry in New Jersey, 11 bore-holes averaging 102 ft. deep, spaced 20 by 22 ft. apart, were charged with 2040 lb. of 60% gelatin and 4475 lb. of 40% gelatin. This blast produced 40,000 tons of stone. A different case is presented by a West Virginia quarry. Seven bore-holes, 60 ft. deep, and spaced 8 to 20 ft. apart, were charged with 1600 lb. of 50% gelatin and 1200 lb. of 33% extra dynamite. It produced 13,000 tons of stone, or 4.6 tons per pound of explosive.

The preceding will serve to give a general idea of what should be expected in well-drill work for blasting. It is important to observe the following precautions, suggested by the DuPont company:

Permit no smoking in the vicinity of a hole being loaded.

See that the men assisting in the work have no matches, especially friction matches, in their pockets. There is a chance of these falling into the bore-hole while loading, producing disastrous results.

Do not allow loose powder to accumulate around the mouth of the bore-hole.

The nails in the sole of a man's shoe may cause sufficient friction to set off the charge. In a dynamite factory no one wearing shoes with nails in the soles is allowed in any of the buildings.

Do not bring all the explosive for the blast at one time, and do not allow it to stand in the open over night.

If possible, complete the loading and firing in one day. If it require more than one day to load the bore-holes, make no connections until just before firing. If necessary to leave it over night, cover the ends of the electric blasting-cap wires with earth. An electric storm during the night often has been known to set off blasts.

Do not prime or connect the charges of explosive for electric-firing during the approach or progress of a thunder-storm. If already primed, keep everyone away until the storm is over.

Be sure that dynamite is thawed before using. Do not cut or try to break a frozen dynamite cartridge, and do not load frozen dynamite in the bore-hole.

The 1918 edition of 'Motor Trucks of America,' of which S. V. Norton, manager of truck tire sales of the B. F. GOODRICH RUBBER CO., is the author, will be ready for distribution on January 1. The book, consisting of 200 pages of reading matter, illustrations, and specifications, is the sixth issued in as many years. Complete specifications of nearly 150 leading gas and electric-driven motor-trucks are contained in the volume. There are 31 specifications for each model. These details are absolutely dependable as the approval of each truck manufacturer is obtained before specifications of his model are inserted. The illustrations add much to the value of the book. Great interest has always been aroused by the introductory articles by Mr. Norton. His previous papers on 'Lengthening the Life of the Motor-Trucks,' 'Devices that Make for Motor-Truck Efficiency,' and 'Fundamental Questions Involved in Changing from Horse to Motor Delivery' have been so much in demand that frequent reprints have been necessary. One great advantage derived from 'Motor-Trucks of America' is that it enables the buyer to get accurate information on all trucks without being obliged to write for all catalogues.

The WELLMAN-SEAEVER-MORGAN Co. announces that it has established a Seattle office which has been put in charge of Glenville A. Collins. The company recognizes the increasing importance of this growing field which deserves careful attention. This will now be given by Mr. Collins, whose offices will be in the L. C. Smith building, Seattle. Prompt service to all friends and customers will be afforded and time will be saved by being able to confer with a responsible agent of the company in the North-West.

Engineers and Dredge Builders

Agents for Bucyrus Placer Dredges on the Pacific Coast, in British Columbia and Alaska

**T**HE title 'Water and Mines in Paradise' suggests a poetic conception of the miner's future state, but, unfortunately, it is the heading to an unpleasant controversy suggesting the wrangles of lost souls in Hades.

**I**T is not often that discussion comes to hand under the stimulus of an article published two years previously. This week such a compliment is paid by Mr. William P. Daniels, in his communication on the extra-lateral right, indicating the vitality of the subject and the aptness of the examples constituting the original contribution by Mr. L. F. S. Holland.

**L**ONDON appears to take a hopeful view of conditions in Mexico. At the recent annual meeting of the Santa Gertrudis company the chairman, Mr. F. W. Baker, said that he believed the years of depression were near an end and that "conditions in Mexico from a political and financial point of view are steadily improving." We hope this anticipation may be fully justified.

**J**ERUSALEM has been captured by the British. Shades of Richard Coeur de Lion! The latest crusade has won its goal and the Moslems are ousted. Now we may look forward to the consummation of the Zionist plan, whereby the Jew may come to his own and Lower Broadway may become less congested. The Saracen is beaten but the Hun is still triumphant; but it is not too much to say that the ideals of Christianity are flouted less at Jerusalem than at Berlin.

**E**XPORTATION of gold in bars, or of gold and silver coin, from Mexico was prohibited by a decree of President Carranza dated September 27, 1917, accompanied by another forbidding the payment of taxes in American banknotes. The Mexican government was wholly within its rights in taking these steps, but it is perfectly clear that it was done in a spirit of reprisal because of the order by the United States against the exportation of gold, which in our case was a necessary war-measure. That Mexico has further designs looking toward restrictions upon the disposal of the output of mines in that country is shown by the criticism of the operations of American companies at Santa Eulalia,

Chihuahua, in a report by an officer in the Department of Mines. He takes the ground that the recent prosperity of that district is wholly fictitious, and that it signifies the depletion of rich Mexican mines for the benefit of "adventurous foreigners." We admit that an American undertaking to do business in Mexico under present conditions must necessarily possess a venturesome disposition, and we also note that the Mexican official making these unpleasant suggestions bears the name of Honigmann.

**I**N referring to the article on the new copper district in northern Manitoba, by Major Karri-Davies, in our issue of October 13, we did not mention the publications of the Canadian Geological Survey describing this region. Those interested in the subject will find that Mr. E. L. Bruce, more particularly, but Mr. A. MacLean also, have published several summary reports, together with a memoir and a special report on this part of the Canadian mineral domain. These papers can be obtained by writing to the Department of Mines, at Ottawa.

**W**E note, with keen pleasure, that Mr. Robert M. Raymond, now Professor of Mining in the Columbia School of Mines, has been nominated a vice-president of the American Institute of Mining Engineers. Many others will share this pleasure. The nomination of Mr. Sidney J. Jennings as president for the ensuing year is in accord with general expectation and is most gratifying. He deserves the honor and should prove an admirable chief. The latest bulletin of the Institute records the proceedings of the Patriotic Meeting at St. Louis, on October 8. We gave a summary of the speeches in our issue of October 27, but we commend the full report to our readers.

**W**E publish abstracts of the reply-affidavits made by Messrs. Edgar L. Newhouse and F. W. Bradley in the suit brought by the American Smelting & Refining Company against the Bunker Hill & Sullivan Mining & Concentrating Company. They refer to other affidavits that we cannot find space to print. For example, Mr. Stanly A. Easton, the manager for the Bunker Hill company, testifies that on June 24, 1915, in Mr. Newhouse's room in the Samuels hotel, at Wallace,

there was a conversation "in relation to the ore situation" and on that occasion Mr. Newhouse stated that "it would be fruitless for the Bunker Hill company to expect to receive from other smelting companies as good or better rates and terms for its high-grade and low-grade ores than would be given by the Tacoma Smelting Company, as there was a better understanding among the various smelting companies who purchased ores in the Coeur d'Alene district than there had been for many years and that a very friendly and co-operative spirit existed among them, and when the representatives of any certain smelter was engaged in negotiating for the purchase of ores it was the present policy of the other companies 'to look out of the window'." It is fair to add that Mr. Newhouse demurs to the accuracy of this statement. This is but the attack and parade of the fencing-bout that precedes the real battle, but it indicates the line of defence.

**O**RDER of deposition of minerals in a vein is a matter of great practical importance to the engineer when occasion arises to pass upon the desirability of developing a prospect. Every examining engineer is required to do some of the work of an economic geologist, because the functions of the two have not yet become fully differentiated. To state it otherwise, the specialist in economic geology is seldom commissioned to examine a prospect; most of that work devolves upon mining engineers, and it is usually the engineer who requests the assistance of the geologist as the development proceeds. Therefore, a scholarly paper such as that which we publish in this issue by Dr. F. N. Guild, on the relations of the silver minerals, will make a wide appeal. It will help in the determination of the primary or secondary character of the ore in cases where oxidation is not in evidence. It may not be important to ascertain this relationship in every case, but where it is necessary to the appraisal of a prospect, it is vital. The article is also noteworthy in its revelations of the limitations and proper use of the reflecting microscope.

**D**ECLARATION of war against Austria will affect a large number of mine-laborers in the South-West and elsewhere. Some of them have been among the more refractory units during recent labor disturbances. Their status now as enemy-aliens will compel them to act, discreetly, for they will no longer be subject to the general laws—State and Federal—but liable to internment or other disposition by executive order of the President. This is one of the regrettable consequences of the War, in so far as it checks the assimilation of sundry European elements in our population, creating foreign islands in the body politic of the nation. Another regrettable consequence is the loss, for military service, of a number of Slovenes and Jugo-Slavs that are technically Austrians but yet willing to fight for the cause. However, the time has come when he who is not with us is against us, and although we may lose the services of

some of these loyal soldiers we shall decrease the danger of the spying and sabotage done by enemy-Austrians that have been playing the German game.

**N**CESSITY mothers opportunity. This has once more been proved in Spain. Inadvertently we did her an economic service when we relieved her from her colonial incubus. Ceasing to dissipate her energies in exploiting peoples across the seas, she then turned upon her own domestic resources of brain and brawn and raw material. Having been shown about the same time the road to sanity in national finance by that splendid Spaniard of the Cervantian type, Don José Echegaray, she has advanced in a more progressive spirit ever since. The War likewise has brought its hardships and its benefits. More than before has it been necessary to develop her native industrial opportunities. Iron smelting has grown rapidly. Furthermore, the search for coal, which had been known to exist in the Peninsula without exciting large interest in the past, has led to remarkable discoveries and to constantly enlarging operations. Spain is proving to possess assets in fuel that ensure a prosperous future. Every week new extensions of the coalfields are reported, and the Minister of Fomento has entrusted this new and growing industry to a special committee known as the Consorcio Carbonero, at the head of which is Don José M. de Madariaga, who is also president of the Council of Mines.

**T**ECHNICAL hand-books in growing number are being issued from the Government bureaus. The U. S. Geological Survey has just produced one that gives a simple and direct account of all methods having the approval of present-day specialists in the drilling of wells. We refer to Water Supply Paper No. 257. The author is Mr. Isaiah Bowman, which means, as in the case of all such governmental treatises, that Mr. Bowman has brought together the conclusions of many men, and that he has enjoyed facilities for gathering information, because he represented the Survey, that would not have been accorded to many private individuals. We mention this excellent manual in this way because the Bureaus are invading the province of the author and publisher of technical books to a greater degree than ever. The projected activities of the Bureau of Mines, for example, will involve the continued publication of treatises on metallurgy, chemistry, fuels, and other subjects, as a result of original research and elaborate investigations into current industrial practice. Evidently, in future, the independent contributor to technical literature will perforce find a field apart, and this may become one of criticism, of careful weighing and checking of results in the discussion of the more minute details of economic operations. The function of departmental technical bureaus will necessarily become limited to the broader principles, in short, to the presentation of standard methods, of which Mr. Bowman's booklet on well-drilling is an excellent example.

## The Threat to Gold Mining

It has been intimated, from Washington, that the Priority Board, of which Mr. R. S. Lovett is director, will discriminate against the mining of gold by declaring railroad freightage for this branch of industry to be non-essential to the conduct of the War. If such a ruling should go into effect, we may expect next that an embargo will be placed on the delivery of explosives to gold mines—a step that would terminate gold-mining activity in hard rock, leaving only dredging as a source of the monetary metal. This is a serious matter—tremendously serious—not only to an important phase of Western industry but to the National welfare. We submit that present conditions call insistently for a generous treatment of gold mining. It is true, the value of the gold held in this country is estimated at \$3,272,500,000 as compared with \$1,871,600,000 when hostilities commenced in Europe, but the obligations incurred by the United States since our own declaration of war have been so great as to decrease radically the proportion of gold to indebtedness, despite the influx of gold from outside. Whereas the National debt was a little more than a billion dollars when we started to make war, it is now being increased at the rate of over 20 billion dollars per annum. Are we to diminish the foundation of our financial security at this time of world-crisis? When England went to war she took steps at once to protect her gold-mining industry by making the arrangements necessary to ensure a supply of cyanide, steel, and other materials required by the mines in South Africa, Australia, India, and Canada. It may be said, truly, that England knew that she would need every available ounce of gold to make payment for the war-materials and food-stuffs to be imported from abroad, whereas the United States can obtain such necessities from within her own borders, so that gold is not required in anything like equal degree for the consummation of the big purchases made at Washington. Our own Government can buy all that it needs from our own people on credit; it issues bonds and notes that circulate freely within the national family; a domestic circulation is established and the day of reckoning is postponed. But a day of reckoning will come; the United States is not, any more than any other member of the civilized world, an island in the midst of an untraveled sea; the inflation of credit cannot proceed uninterruptedly; we must be prepared for the inevitable deflation; and when that day comes the nation must be able to stand not on the shifting sand of fiat paper, but on the firm foundation of a gold reserve adequate to maintain stability. We suspect that the bureaus and committees at Washington have yet to compare notes, in order to crystallize policy into far-sighted action. It is imperative that no such serious step as an embargo on gold mining should be taken until the facts have been well considered. We venture to suggest that this careful consideration is lacking. Just as the Controller of Fuel and the Controller of Food were in disagreement recently concerning the priority to be given

to the transport of fuel and food, respectively, so also different departments of the Government appear to be at variance in regard to the need of gold. When the shipment of steel plates to Japan, which has been building ships for use by the Allies, was stopped by order from Washington, there began a withdrawal of gold from the United States to Japan. In return for steel we had been receiving Japanese products, such as silk and soya-bean oil, in exchange, without trenching upon the reserve of gold. As soon as this international exchange was stopped, it became necessary to export bullion. Again, a number of employees of the Baldwin Locomotive Works, in the service of the Government, were about to go to Russia in performance of duties immediately contributory to the success of the War; as Russian exchange had collapsed, it was impracticable to do business with paper, so these engineers and mechanics were furnished with gold amounting, in the aggregate, to \$10,000, which was distributed among them on the eve of their departure from Seattle. The port authorities stopped the removal of this gold to Russia. Further, we are informed that the Californian management of gold mines in Salvador was accorded facilities for the shipment of supplies on the express understanding that the bullion would come to this country. A consignment of candles, for use underground, was held up under the embargo placed upon the export of tallow until the destination of the bullion output of the mine was made clear. These three examples appear to indicate clearly that one or more departments of the Government are awake to the real economic position. We submit that the freightage incidental to gold mining is so small in proportion to the value of the product that the proposed embargo is illogical. For example, a gold mine, such as the Plymouth, in Amador county, producing concentrate that is shipped to a smelter, requires one car inward and three outward per month on an annual production of \$1,000,000 worth of gold. The group of mines at Grass Valley contributes \$3,000,000 per annum in gold while using only two cars per month on inward freight, all the gold being shipped as bullion in parcels so small as to weigh only five tons per annum. Coal, or other fuel requiring transport by rail, is not consumed by our gold mines, their machinery being actuated by hydro-electric power. The smallness of the freightage incidental to gold mining is an outstanding feature of the industry; it appears to be one of which the members of the Board of Priority are not aware. We commend it to their serious attention. Further, we deprecate the recruiting of men in the gold-mining districts for employment at the copper mines. An idea prevails in some quarters that copper and lead are more necessary for warfare than gold. We demur to that; and we believe that thoughtful financiers will do so likewise. For example, we wrote to Mr. Otto H. Kahn, of Kuhn, Loeb & Co., a man conspicuous today for his intense loyalty as also for his keen intelligence, and he replied that in his opinion "the production of gold is a necessary war operation." Are we going to discard one of the advantages we hold over the Enemy? Of the

world's gold production 60% is produced under the British flag, 20% is produced in the United States, and 5% in Russia; thus 85% of the total is in the hands of the Allies. Of the remaining 15%, only 2% is controlled by the Enemy. Here we have an economic factor that, if properly used, should go far to strengthen our arms. Is it not foolish to forego this advantage?

## Harnessing a Volcano

To utilize the movement of the tides has long been the fancy of the mechanical genius; to convert the heat of the volcano into economic units has been the dream of the physicist. It is interesting to record a successful effort to put the more visionary of these ideas into action. A consular report from Florence describes experiments made near Volterra, in Tuscany, where volcanic steam issues from fissures in the ground along the Cornia river. Early in the 19th century a Frenchman, François de Larderel, analyzed the steam and discovered that it contained enough boracic acid to warrant economic extraction. He built a plant close to the largest fissure and laid the foundation for an industry that is now identified with the town of Larderello. The vent is covered and the steam is condensed into water from which the boracic acid is precipitated in crystalline form. The evaporation of the liquor and the subsequent drying of the crystals are aided by the heat of steam issuing from the fissures. Likewise the offices of the company and the houses of its employees are heated by the same natural agency. Several years ago it was decided to use the surplus steam from these volcanic fissures to drive a small horizontal engine. This was done by utilizing the heat of the steam to vaporize water. When the low-pressure turbine was invented, another experiment was tried. Borings showed that no diminution of steam-pressure from the vents was caused if the borings were of sufficient distance—not less than 50 feet—apart. Bores were made to a depth at which a pressure of two to three atmospheres and a temperature of 310° to 380°F. could be obtained. Through pipes in the bores the steam is carried from underground into tubular boilers, the heat of which is used to turn pure water, derived from other sources, into steam, which, in turn, actuates the engine driving a dynamo. The electricity thus generated is transmitted and sold to neighboring towns. At present three sets of turbine-alternators of 4000 horse-power each produce a three-phase 50-cycle 4000-volt current, which is transformed to 16,000 volts for transmission to the near-by towns or to 40,000 volts transmitted to more distant points. Although utilization of natural energy is on a scale relatively small, it is immensely suggestive. Man has bridled the wind to his travel, he has tamed the waterfall to do his service, and made the lightning carry his word. As yet the ocean has defied his discipline and the volcano has mocked his control. In the tidal motions and in the volcanic fires he sees two great forces that remain outside his authority. The lunar attraction is not wasted, so it may seem to him, for twice it performs its

cleansing function on earth's shores, but the subterranean heat is to him only the touch of devastation. Shall we be able to put it to beneficent purpose? Before all the coal is consumed shall we not learn how to generate light from the dying moon, through the service of the tides, and how to win heat from the volcanic glow that comes from the earth's warm heart?

## Flotation

Our contemporary at New York publishes a belated criticism of the recent flotation decisions. This is written by Mr. R. C. Canby, who was an expert for the Miami Copper Company in its suit with Minerals Separation. Two facts emerge from his lengthy contribution: One is that the author was making experiments with the porous carborundum wheel, covered by the Towne patent, for the Teziutlan Copper Company, at a time precedent to his tests with the Minerals Separation machine at the Miami mine. His early work was based on the Elmore vacuum process, not patent 835,120. Another fact is the discarding of the Pachuca tank, more properly called the Brown agitator, in connection with the Callow machine, at Miami, just before the hearing of the Miami suit at Wilmington. We cannot understand why Mr. Canby and the other experts acting for the Miami Copper Company should have made the blunder of using the Pachuca, or why, having once used it, they did not make it clear to the Court, then instead of now, that the Callow machine, or pneumatic process, was effective without the aid of any sort of violent agitation. If they had, the decision of the Court would have been different, there is good reason to believe. Again, why did they not demonstrate that the Elmore vacuum patent was the 'prior art' from which they derived the pneumatic method. It seems to us that the Miami case was badly managed. Also the Hyde case; for the demonstration that the 'critical' proportion of oil was a fallacy—that good results could be obtained in the mill when using more than 1% of oil—was not made until after the Supreme Court had given its decision; indeed, it was demonstrated within a few weeks thereafter—too late. The Anaconda company did the mining industry a poor service by hastening to make its contract with the Minerals Separation people, but, on a purely business basis, this contract aided the Inspiration company, which had previously and too eagerly adopted the Minerals Separation machine, because the Anaconda contract superseded the Inspiration contract and gave the two companies a low royalty on the basis of their combined tonnage. Today the Minerals Separation machines in the Inspiration mill have been replaced by machines of the Callow type, except for one Hebbard (a modified M. S. machine) out of the 20 flotation-cells in use. This in itself is pretty good evidence, as Mr. Canby suggests, of the American contribution to the flotation process. Is it not a fact also that patent 835,120 was seven years old before the Minerals Separation people applied it to the concentration of copper ore in the United States?

## Extra-Lateral Right

The Editor:

Sir—My attention has recently been called to a discussion of extra-lateral rights in your issues of December 18, 1915, and February 12, 1916, the reply to the

FIG. 5

FIG. 6

inquiry of E. B. Durham in the latter article being of peculiar interest because the question arose with us some years ago, and our attorney, the late George C. Redd, advised us that the triangle  $MLG$  in Fig. 6 [herewith reproduced] did not belong to any surface claim; that it could not be located on the surface; but that anyone reaching the triangle by any working could locate it in such working. Mr. Redd stated that he had searched for authorities and decisions but had been unable to find any; that he had consulted a number of attorneys, among them Judge Morrison, and that all agreed with him. If there have been decisions definitely settling the

matter, as stated by the attorney who replies to the inquiries for you, it would be interesting to me and probably to others, if you would cite them. It would seem to me that the opinion of Mr. Redd ought to be correct, and that it would be, by long odds, the most equitable settlement of the matter.

WM. P. DANIELS.

Denver, Colorado, October 21.

[The case to which our correspondent refers, taken from the article which he cites, is the following:

"A. Where the vein cuts both side-lines, are there any limits to the application of the rule that the original side-lines become the end-lines that limit the extra-lateral rights? Suppose in Fig. 5, the vein crossed line  $AB$ , near  $B$  and the line  $DC$  near  $D$ , and dipped north, that is, parallel to the line  $BC$ ; then if the rule held, the extra-lateral rights would be nearly on the strike and also the width of the claim might exceed the maximum of 600 ft. provided by the U. S. law.

"B. Where there is a conflict between two claims, the rule given by Lindley in the next to the last paragraph seems reasonable. If Fig. 6 is drawn with the boundary lines extended, as per sketch herewith, in accordance with the rule given, there is a triangle  $MLG$  on the vein, with its apex  $L$  far underground, which has no owner. How can ownership be acquired to this piece? My idea is that additional claims would have to be located along the outcrop of the vein adjoining the Last Chance with their end-lines parallel to the line  $LM$ ; these might have no surface rights and their extra-lateral rights would not commence until the vein had passed beyond the rights of the New York claim."—EDITOR.]

## Water and Mines in Paradise

The Editor:

Sir—Under the above heading an article signed by J. D. Hubbard appears in your issue of November 3, in which he takes exception to certain statements made by Ivan E. Goodner, Chief Engineer of the Paradise Irrigation District, in an article appearing in your paper some time ago, and saying that the remarks made by Mr. Goodner are not only inaccurate, but untrue.

Mr. Hubbard writes: "The first statement is that 'None of the owners of the land referred to has so appeared at any time in the past, but all have paid the tax levied without protest.' How about the Mineral Slide Mining Co. in Sec. 10, T. 23 (22), R. 3, M.D.M? Mr. Goodner not only protested, but forced withdrawal of their property from the irrigation district."

I wish to say that as the Mineral Slide Mining Co.'s property has never been in the district, there has never been, nor could there be, any withdrawal from the district, forced or otherwise.

Mr. Hubbard further writes: "The land in question includes 54 acres, not 20, and the tax levied was \$5 per acre instead of \$1."

The tax levied was 20 cents per acre, as Mr. Hubbard well knows. He may perhaps remember that I was present when he paid it. The total tax on the 54 acres was \$10.80.

Next year, Mr. Hubbard says, the tax will be \$1 per acre. This statement is not true either; this tax is 4 cents per acre, a total of \$2.16 for the entire tract. The valuation of the tract in question is 1/60 of that placed on the best land without improvements. This shows that the assessor has not refused to consider the quality of the land. So far no water has been furnished to anybody. When the system is completed, Mr. Hubbard, or whoever the owner of this 54 acres may be, may feel certain that he will receive the full amount of water to which his \$2.16 tax entitles him.

G. C. BILLE, Secretary,  
Paradise Irrigation District.

[This closes the controversy.—EDITOR.]

## A Method of Mining

The Editor:

Sir—Would you please state the best and quickest way to mine the ore and to remove the waste in a block

of ground such as is indicated by the accompanying sketch? The vein is three feet wide and we are drilling by hand, using five-eighths of an inch steel. We pay one yen, or 50 cents, per shift of eight hours. The hardness of the vein material is equal to that of average quartz, and the country-rock, which is Iparite, is only moderately hard. The vein dips at 75°. The ground stands well, but it would exert considerable side pressure over any large stope, that is, one over 100 ft. long. There is little or no rock for filling, unless specially broken in cross-cuts. The ground to be stoped is from 1000 to 1500 ft. below the surface. The main drift is 5 by 7 ft. inside timbers. There is considerable water, but the vein-filling does not fall out. The waste is often consolidated by the water if left too long broken in the

stopes. If you will kindly indicate the approved American way of mining such a block of ground under such conditions I shall be much obliged.

Ashio, Japan, September 2.

TAKEO IGAWA.

The Editor:

Sir—I have noted the inquiry of Mr. Takeo Igawa headed 'A Method of Mining,' and have the following to suggest:

In formulating a system for stoping the particular ground referred to, one should keep in mind two additional essential points, which are not referred to in the inquiry, namely, the value of the ore and the supply of timber.

Assuming that the material carries sufficient valuable metal to be classed as 'ore,' and that timber is easily obtainable at a reasonable cost, I would suggest that, having regard to the fact that the walls are stated to exert considerable side-pressure over a large opening, the ground should be taken out on vein square sets; that alternate sets be filled with waste (the waste to be taken from half-raise cross-cuts in the hanging wall), these cross-cuts to be made at points where waste is required, and that whatever waste is broken when the vein is shot down shall be sorted and used as filling. Thus the ore can be mined clean, and the walls supported, which I believe would suit the requirements of such a block of ground as is described by Mr. Igawa.

If the walls will stand it, it might be found cheaper to simply open the level with ordinary tunnel-sets, placing chutes at intervals of 25 or 30 ft. These sets may be cribbed upward, as the vein is removed, and the stopes filled with waste from hanging-wall cross-cuts. By this method the stope would be filled completely with the exception of the ore-passes and manways, which can be distributed in accordance with the desires of the engineer, having for their purpose the convenience of passing the ore to the level below without having to use anything but a shovel in the stope.

If this method be adopted, the walls will not be supported between the top of the filling, and the vein can be left intact.

W. J. L.

San Francisco, November 13.

The Editor:

Sir—Answering the inquiry of Mr. Takeo Igawa as to the best methods to handle his mine, I would say that two methods are available.

I would advise opening the mine with levels not over 100 ft. apart, starting from the top of the orebody, or at the 1000-ft. level. If the ore-shoots are long, I would advise driving raises at intervals of 75 to 100 ft. along the shoot. These raises should be well timbered to take the strain of the walls; in this way, the

stopes can be worked just the same as we worked the small stopes in the Cripple Creek district, which was by stulling and an occasional wall-plate to hold any piece of ground that was blocky.

The other method I have in mind would be to leave pillars of ore at regular intervals. Work the mine on the open-stope method and leave pillars of ore about every 75 ft., the pillars to be from 25 to 50 ft. long; then when all the ore has been removed outside the pillars on a level, start at the back of the drift and draw the pillars. The wall-rock being liparite, which is really rhyolite, should stand well; where blocky ground is encountered, wall-plates can be used back of the stulls. This last method is only advisable where timber is expensive.

As Mr. Igawa is driving his drifts 5 by 7 ft. inside timbers, these will have to be at least 7 by 8 ft. outside timbers; this will give him 32 cubic feet of waste for every foot of drift. This waste he should hoist to the upper levels and dump into the stopes as filling. If later he finds it best to fill the stopes further, this can be done by a series of holes drilled into the hanging wall, shooting it down directly into the stopes.

As his vein is only 3 ft. wide, I would advise that he do not bother with filling the stopes at all. The ground will not break away enough to endanger the mine at any time. The walls are of such a nature that they are not at all dangerous, at least, this is what we found to be the case at Cripple Creek. After they have been left open for a long time, the rhyolite will swell and crush the stulls and commence to fall out in blocks, but the waste-rock that he has dumped into them from his drifts will act as a cushion on top of the drift-timbers.

He cannot use the shrinkage system at all as the water will tend to pack his ore in the stopes and make it very difficult to remove.

To sum up, I would open the mine by the open-stope method with levels not to exceed 100 ft. apart, stulling the stopes and putting in wall-plates wherever the ground showed a tendency to be blocky and not bother to fill the stopes. With his low cost of labor, he might find it an advantage to run his drifts at intervals of 50 ft., which would give him such low stopes that he could easily get out all the ore before any of the wall began to come in. In this way, he would be well out of the level when the hanging wall did cave, and as it cannot come over three feet, this is not enough to endanger the mine in the least.

A. W. S.

Piedmont, California, October 28.

[This appears to be a simple case. In California the ground would be excavated for a stoping-width equivalent to the thickness of the ore—3 ft.—by means of the hammer-drill, shooting down on platforms supported by stulls. The ore would be dropped through chutes, either cribbed or lined with 2-inch boards, delivering to the cars on the level below. The stulls used during drilling

will protect the men at work and hold the ground long enough to permit of removing the broken ore. After that the stoped area can be allowed to cave. If the rock swells it will be unnecessary to fill.—EDITOR.]

## Control of Emulsions in Flotation

The Editor:

Sir—The paper on 'Control of Emulsions in Flotation' by Courtenay De Kalb, in the MINING AND SCIENTIFIC PRESS of August 18, has been read with great interest. It seems to me that the author is setting out with the theory that the mineral is to be oiled; that the oil is first to be emulsified and then delivered to the mineral in the proper state of division. My conception of the happening in the process is somewhat different. The formation of hydrophilic colloids in the flotation process I believe is an absolute necessity; without the formation of these colloids there is no flotation. The presence of oil, however, seems to be unnecessary. I am daily conducting tests and am obtaining results without any oils. In order to analyze the condition which may exist in the flotation process we must, of course, examine the art and come to the conclusion whether there is one flotation process or whether there are two flotation processes. Without referring to legal matters it seems that the Minerals Separation Co. at least takes the stand in accordance with their patents, that there are two flotation processes; one which uses as its medium an immiscible substance and another which uses as its medium an absolutely soluble substance. The patent 962,678 when read carefully leaves no question as to the assertion that the soluble frothing-agents act while in solution, and a disclaimer contained in the patent emphasizes this. In accordance with this theory then we would have two distinctive processes accomplishing the same result. My work so far does not bear this out, and in this discussion I assume that the action in both cases is the same.

It is certainly of vital importance to the development of a theory, and, in turn, to the development of the flotation process, to know whether we are dealing with two actions or with one. I believe that we are dealing with identically the same action in either case. It is, of course, self-evident that in using such sensitive reagents as oils in the complicated mixtures that exist in a diluted ore-pulp a great many chemical changes are bound to take place. In tracing several reactions I am constantly consulting the literature on organic and inorganic chemistry, and while many reactions are totally unknown, there are enough facts available to illustrate the enormous possibilities. Another strong factor in flotation is the oxidation of the reagents, caused by the enormous volumes of air rapidly dispersed through the pulp. Without going into the possibilities or probabilities, I believe it can be stated that the majority of the soluble frothing-agents will be chemically changed on entering the flotation-cell, on account of the alkaline and acid mixtures, and in contact with the metallic oxides and other substances present. A certain amount of research-work in that

direction has convinced me that it is possible to make, under the identical conditions present in the flotation process, oils from non-oils. A number of the so-called soluble frothing-agents become insoluble after a period of agitation. Furthermore, I have found that, when the soluble frothing-agents do produce results, with absolutely no oil used and with particular care being taken that no oil should be in the circuit, hydrophilic colloids were present when the frothing took place. On the other hand, no frothing can be obtained with strictly saturated hydrocarbons. In making this statement, I must point out that, in order to obtain saturated hydrocarbons, absolutely free from organic oils and acids, one must go to considerable trouble. All the commercial products contain sufficient organic substances to yield misleading results. In comparing thousands of tests, I find that, first of all, if I wish to float with oil, the oil must have a soluble portion.

I believe that under the proper treatment most organic oils used are almost entirely soluble. Whether they first go into solution and then re-precipitate as hydrophilic colloids is undetermined, but I believe that these oils are not present as droplets but as hydrophilic colloids. This seems to be borne out when flotation is accomplished by soluble substances. It has been manifest in all tests that I have made, that these soluble substances are precipitated as hydrophilic colloids. Seldom are conditions such that an oil may be formed from these soluble substances, although I think this is entirely possible, but it does not seem to be necessary. If it is not necessary then the flotation phenomena evidently exist without the presence of oil, but never without the presence of hydrophilic colloids. The suspicion must naturally arise then that the hydrophilic colloids are directly responsible for flotation. The proper form of these colloids, of course, has much to do with the coherence of the froth. They may be present in the proper chemical composition but not in the proper physical form, and an unstable froth or perhaps a completely negative result may follow. For instance, we all know that heat has a great deal of influence on flotation, and I have observed that finely disseminated colloids at, say, 30°C., will group themselves closely at 50°, and will re-assemble in drops at 80°, and in that condition they will be useless for flotation. Raising the temperature, however, to the boiling point, flotation may again be accomplished. These temperatures, of course, are relative to the substance used. The 'critical temperature' is always that temperature which causes the colloids to collect into droplets or into drops.

The second method of varying these results is by the addition of quite insoluble oils, that is, saturated hydrocarbons. The action due to the saturated hydrocarbons or mineral oils is almost identical with the action of heat, that is to say, these hydrocarbons have a faculty for collecting the colloids, thus ending their usefulness. This action is the underlying reason for the error of the assumption that more than 1% of oil will not give any result. Most commercial products contain a certain amount of mineral oil, and when used in excess introduce

enough mineral oil to collect the hydrophilic colloids, and hence to eliminate their usefulness, while, perhaps, when a small amount of mineral oil is added to any suitable quantity of organic oil, the resulting formation of colloids will be such that the elastic limit of the groups is increased, and their capability of surrounding air and forming air-bubbles and froth is therefore improved. The absorption of water by these colloids has a great bearing on the process because, in the concentration of 5 tons of ore into one ton of concentrate with the application of 10 lb. of oil per ton of ore, 50 lb. of oil is used to lift one ton of concentrate, assuming that the ordinary depth of a flotation-cell is 2 ft. This then exerts 4000 ft.-lb. of energy, or is a condition under which such energy is rendered available. Without being hydrated, the oil would not have the necessary elasticity for surrounding sufficient air to exert that enormous power, but having absorbed so much water and having thereby enlarged its bulk many times, a comparatively small amount of original reagent used is sufficient to carry the mineral.

The above leaves open the question of the preferential affinity of these colloids to mineral. While I have adhered for years to the theory of a chemical reaction between the mineral and the flotation reagent, I consider it entirely possible nevertheless that we are dealing with a surface-tension pure and simple. The fairly successful operation of various surface-tension methods is illustrative of this possibility, and the lack of complete success may lie only in the fact that the surface-area exposed was too small, and the success of the froth-flotation method may lie only in the increase of surface-area. The fact that different minerals will froth with different reagents does not necessarily exclude that possibility. Different minerals unquestionably will require for their successful flotation a changed condition as to the surface-tension, and that may be influenced by the type of colloids produced. I am at present successfully floating lead from zinc, not making an imperfect separation, but as nearly complete as that of any other mineral floated from its gangue, and I have strong indications that the surface-tension was responsible for this effect. I have ventured, in the above, to give my views, not to convert others to my theory, but merely to furnish material for further discussion.

ALFRED SCHWARZ.

Webb City, Missouri, November 22.

In precipitating copper from sulphate solution with  $SO_2$ , the solution is neutralized with lime and treated with the sulphur di-oxide until it has dissolved a proportion of the gas equal to that of the contained copper. The precipitation of metallic copper takes place instantly when this solution is heated to 160° C. under a pressure of 100 lb. per square inch.

Pyrite from domestic sources is quoted at 20c. per unit of contained sulphur, this being the highest price yet reached.

# Displacement-Tanks

By WALTER S. WEEKS

The general principle of displacement-tanks for measuring the air-consumption of rock-drills is known to all mining men, but it takes a good deal of experimenting to construct them so that they will work properly. It is hoped that these few suggestions will be helpful.

The elements of the displacement-tanks are two closed tanks connected with a pipe at the base and equipped with valves so that air may enter one while leaving the other. The air in the two tanks is always separated by a piston of water, which flows back and forth from one tank to the other. The change in level of the water in one tank multiplied by the area of the tank is the volume of air that has flowed out.

It will occur at once to the reader that there are two possible ways of measuring the volume of air displaced. In the first method we place on one tank a gauge-glass that reaches from the top to the bottom. We can read the gauge-glass at the start and after a given elapsed time, say, a minute, read it again. From these readings we can compute the flow of air per minute. The main drawback to this method is that the tanks must be perfectly regular from top to bottom, or else the volume must be calibrated in many places.

In the second method we place two small gauge-glasses on one tank, one at the top and one at the bottom, and find the volume between two marks on the glasses. If we take the time for the water to rise from the lower mark to the higher with a stop-watch, the volume flowing per minute can be calculated. With this type of meter, tanks of any shape can be used.

The air entering the tanks must do so at constant pressure. A reducing-valve is needed. I have tried many kinds and the most satisfactory one is comparatively inexpensive. It is made by the Westinghouse Air Brake Co. and is known as the S 4 locomotive governor. The price is \$21. It should be fitted with a hand-wheel so that it may be regulated easily. It should be arranged as shown in Fig. 1 (a). (All references will be to Fig. 1 unless otherwise specified.) The control-pipe *b* should not be connected to a tank because the valve continuously exhausts air to the atmosphere. A lubricator *r* should be placed on the control air-line feeding very thin oil to the valve.

The air, after passing the reducing-valve, must enter first one tank and then the other and when it is entering one it must be leaving the other. These operations require a four-way valve. The stock four-way valve is costly and generally leaks. An excellent four-way valve can be made with four single valves *c* arranged as shown, with levers, so that they can all be thrown together.

The valves are made by the Westinghouse company and are known as 1-inch cut-out valves. They cost \$1.80 each. In the pipe *d* connecting the tanks at the bottom should be placed a quick-closing gate-valve *e*. It is necessary to measure the volume of but one tank. Glancing at Fig. 1, place a mark on the gauge-glass *f* and fill with water to that point through the pipe *g*. Close the gate-valve. Draw off water through the pipe *g*, carefully measuring it until it comes in sight on the glass *h*. Now draw carefully until an even number of cubic feet is reached and mark point on the glass *h*. When the water in tank II rises from the lower mark to the higher, the measured volume of air has been displaced.

To obviate the necessity for watching the gauge-glasses

FIG. 2. CONTACT-PLUG

I have arranged for a bell to ring at the two critical points. It is done by fitting up spark-plugs so that a contact is made between the tank and the sparking point of the plug by means of a float. The principle is shown in Fig. 2. An ordinary automobile-plug fitted with a float is tapped in at *i*. A plug built as shown in the drawing is placed at *k*. The plug is so constructed that the point of ringing can be controlled by screwing the centre point in or out. The plug *k* is placed on a line with the mark on the gauge-glass. A water-glass should be placed opposite the plug *i*, as shown.

To put the apparatus in working order the water is run up in tank I until the bell rings. The gate-valve is closed and the water in tank II is brought to the lower mark. The gate-valve is then opened and the water is forced to the upper mark. The gate-valve is again closed and the spark-plug *k* adjusted by turning the nut *n* (Fig. 2) until the bell rings at this point. Thus it is seen that

between two ringings of the bell the measured volume of air has flowed out. The time is taken with a stop-watch.

To test a drill, connect the hose at *l* and start the drill running. Run water into tank I until the bell rings. Throw the valves and while the water is falling to the level of the spark-plug *i* adjust the reducing-valve. Start the stop-watch when the bell stops ringing and stop it when the bell starts again by contact being made at *k*. To hold the pressure constant the reducing-valve must be changed slightly owing to the small change in hydraulic

head on the air. A run of any duration may be made by throwing the valves at each ringing of the bell and keeping account of the number of throws.

The volume between marks on tank II should be about 16 or 18 cu. ft. for ordinary drill-testing. Means should be provided to exhaust the air in the tanks to the atmospheric pressure if necessary. In the tanks shown in the drawing it is accomplished by a three-way valve at *m*. Charts may be plotted for different gauge-pressures with time in seconds between bells, against free air per minute.

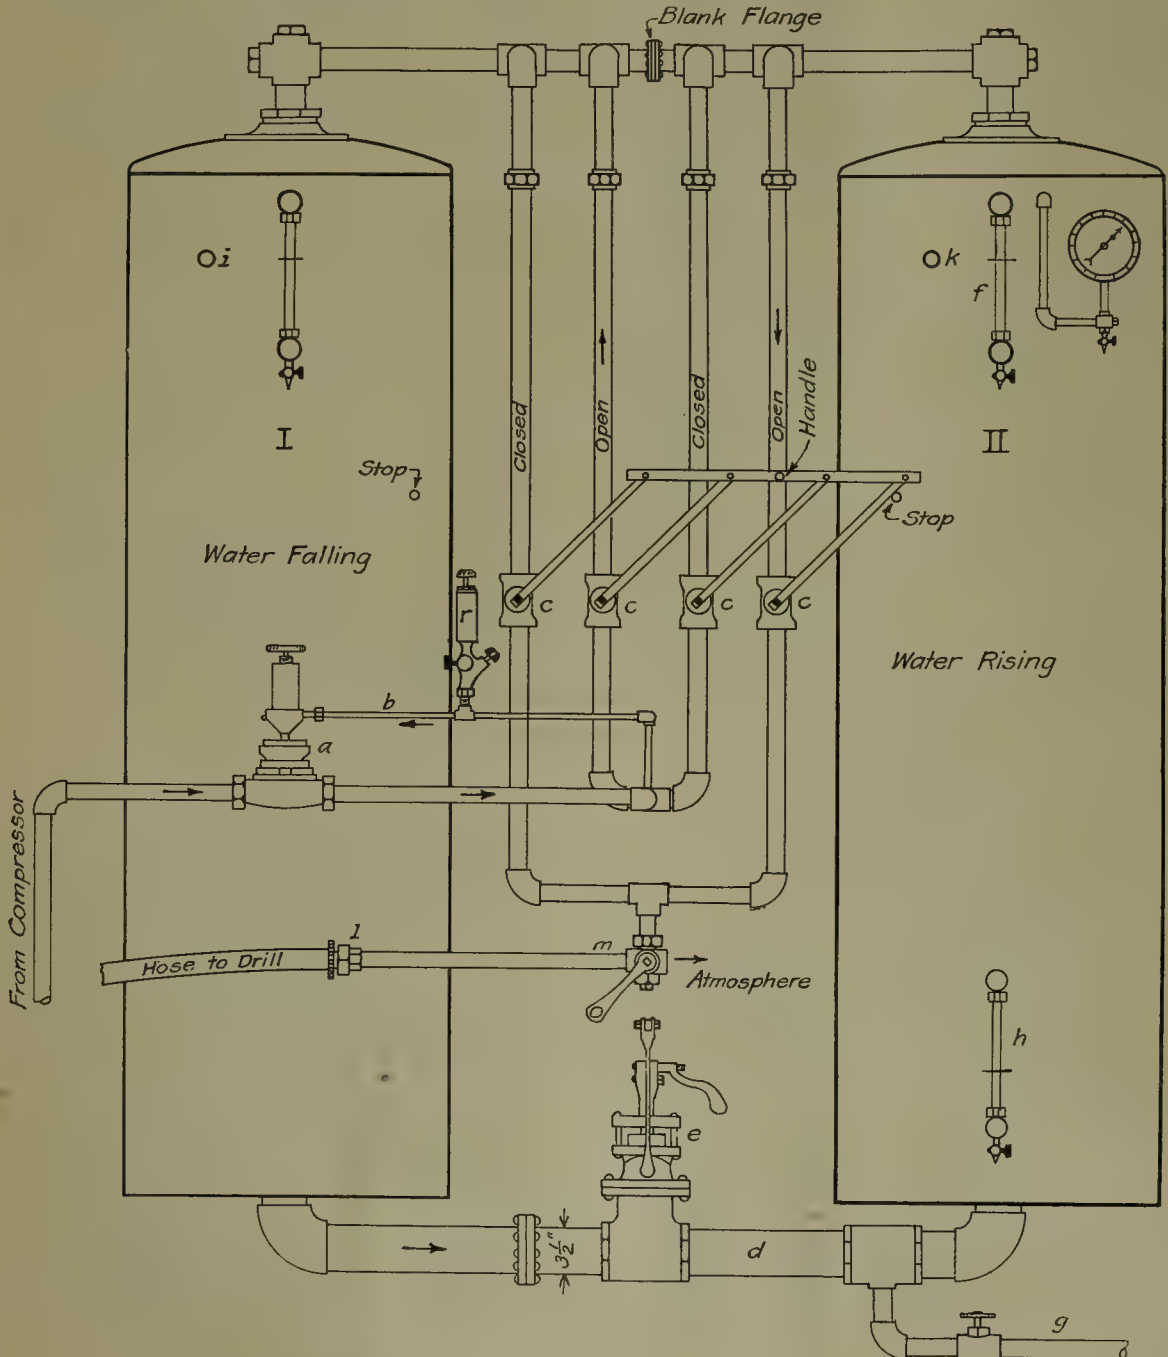

FIG. 1. ELEVATION OF METER

# Microscopic Features in Silver-Deposition

By F. N. GUILD

\*Since the epoch-making paper by Graton and Murdoch on the copper minerals,<sup>1</sup> the value of the study of polished surfaces of ores by means of the reflecting microscope has been fully appreciated. Following these researches the method has been found of equal interest and value in the investigation of many other classes of opaque minerals. Thus Tolman and Rogers, in applying these methods to the magmatic ores,<sup>2</sup> have arrived at important conclusions regarding the relationship of the ore-minerals to the rock-forming silicates. While investigating certain copper and silver specimens from the Silver King mine, near Prescott, Arizona, I became impressed with the need of more detailed knowledge of the relationships of the silver minerals. I therefore investigated, by means of the reflecting microscope, all the classes of silver ores available and published the results.<sup>3</sup> Some of the more important features are reproduced in this paper.

While it has been held that the rich silver minerals have been deposited later than the other sulphides, the microscopic details of the process have not been described, neither has it been shown how the lean silver minerals break down into those richer in silver that replace other minerals or migrate to other portions of the deposit, thus giving rise to a process of enrichment similar to that observed in most copper deposits. Frequently the copper minerals are also present, and the process of copper enrichment has then progressed side by side with that of silver enrichment. This is well illustrated in Fig. 7, where chalcopyrite has been replaced by bornite, and then has later been replaced by chalcocite and stromeyerite. The ore has been further enriched by the break-down of stromeyerite into native silver. In silver deposits pyrite is most often found to be the first sulphide deposited. It may be preceded by arsenopyrite when that is present. Sphalerite and tetrahedrite are the characteristic early sulphides to follow. Tetrahedrite usually shows rather indifferent relations to sphalerite, but is occasionally found definitely replacing it as shown in Fig. 4. Galena is later than tetrahedrite and in those deposits rich in tetrahedrite it is found actively replacing it. The general order of deposition of the various classes of silver ores will be outlined in the résumé.

GALENA. This mineral is believed to be one of the early sources of the richer silver minerals, and therefore it is a matter of great interest to determine the form in which silver is found in galena. There are at least three possibilities. First, the silver molecule, usually thought to be argentite, may be present as a solid solution or isomorphous constituent; second, it may occur as inclusions or microscopic particles of definite minerals; and, third, it may occur in the form of sub-microscopic particles. Nisson and Hoyt have conducted laboratory experiments with the hope of throwing light on the subject.<sup>4</sup> They found that lead sulphide when fused was capable of absorbing or holding in solid solution on cooling somewhat less than 0.2% silver sulphide. The excess separated out in the form of definite grains of argentite as shown by their photo-micrographs. These experiments were not performed under the same condition of temperature as that which existed in the vein when the deposition of the galena took place and therefore are not conclusive. It is possible that quite different relationships between the two sulphides exist at the temperature of deposition from aqueous solution. Nevertheless field observations have strongly suggested conclusions similar to those arrived at by Nisson and Hoyt. Thus, in the silver deposits of Bingham, Utah, Boutwell found those ores to assay highest in silver which contained the largest amount of some other silver mineral, in this case tetrahedrite (freibergite). Ranking next to these were the 'black sulphides' thought not to contain tellurides, and last of all the pure galena samples.<sup>5</sup> In the silver deposits near Lake City, Colorado, Irving and Bancroft report that "little of the argentiferous galena is rich in silver in any of these districts unless accompanied by tetrahedrite or some rich secondary silver mineral." Surfaces were polished, and when no admixtures were observed the assay-values indicated only 10 to 15 oz. per ton.<sup>6</sup>

A large number of specimens of argentiferous galena from various localities was investigated by the study of polished surfaces and by quantitative determinations, and many instructive features were observed. On etching the surface with nitric acid or hydrogen peroxide all galena grains showing over 0.10% silver revealed an appreciable number of spots of either argentite or tetrahedrite, and frequently both. These spots are frequently so minute that even when present in

great abundance, the percentage of silver was not raised above 0.39. Such a specimen from Rimini, Montana, is illustrated in Fig. 1. In this specimen the microscopic inclusions are of four distinct minerals, three of which could be identified. Tetrahedrite appeared harder than galena and could be recognized by its relief. Moreover, it could be compared with other grains in the specimen of sufficient size to permit of micro-chemical tests. Argentite appeared slightly softer than galena, and was practically invisible before etching. Ruby silver could also be distinguished by its bluish tint as compared with galena. The fourth mineral was either some of the sulpho-salt minerals of silver or some soft lead or copper mineral. Only when the spots were of considerable size, in fact large enough to be visible with the hand lens, did the percentage reach 0.50 silver. These, then, begin to show evidences of later addition of silver minerals, with the exception of those showing tetrahedrite. The mineral then has the characteristic appearance of residual grains left behind in the replacement of tetrahedrite by galena. Ores that owe their richness in silver to tetrahedrite have therefore not been enriched by subsequent additions. The later entrance of the rich silver minerals is illustrated in Fig. 2 and 3. In Fig. 2, representing a polished specimen from Tonopah, Nevada, the spots are proustite, and are associated with veinlets of the same mineral that do not show in the photograph. In Fig. 3, taken from a specimen obtained at the Reco mine, Sandoz, B. C., pyrargyrite is seen following cleavage-directions in galena. The specimen, as assayed by methods described below, contained 0.54% silver.

On the other hand, specimens of argentiferous galena that show on etching only occasional spots of silver minerals, were found to contain less than 0.10% silver. Thus, galena from the Bunker Hill mine, in Idaho, only now and then showing one spot in the field of view (No. 5, Leitz objective) contained 0.08% silver. A specimen from the Hercules mine, with occasional spots, gave 0.108% silver. Areas in the same hand-specimen, with 25 to 30 spots in the field of view, contained 0.24% silver. A specimen of galena from the Old Yuma mine, Pima county, Arizona, showed no spots over large areas. This contained only 0.016% silver. These results show that silver may exist in galena to the extent of nearly 0.10% in the form of sub-microscopic particles or as solid solutions. Perfect isomorphous mixtures with the silver minerals are certainly not formed. Above the limit mentioned, spots of silver minerals begin to appear in constantly increasing numbers as the percentage of silver rises. The number given above, when converted into silver sulphide, is close to the figure found by Nisson and Hoyt for artificial mixtures.

The method of procedure in making the determinations described consisted in selecting from the polished surfaces as pure areas as possible, etching with nitric acid, and, after examining with the reflecting microscope, breaking with a sharp awl sufficient of the material for

seorification and cupellation. From 100 to 500 milligrammes was found sufficient except in the case of the very lean specimens, when one gramme was taken when possible. The spots were found to be grouped unevenly, hence care had to be exercised not to cut too deeply, as that would decrease the possibility of representing different conditions from those recorded on the surface.

**TETRAHEDRITE.** Tetrahedrite, when argentiferous (freibergite), becomes an important source of silver. Analyses in Hintze's 'Handbuch der Mineralogie' show as high as 36.90% silver. This is usually present as an isomorphous mixture of some silver mineral. It may, however, be enriched by the later addition of ruby silver which appears in cracks and cavities. Microscopic investigations show tetrahedrite to be a more prolific source of the rich later silver minerals than is galena. Indeed, much of the galena in silver deposits has replaced tetrahedrite and its silver content is due to residual spots of silver-bearing tetrahedrite as well as, perhaps, argentite resulting from the break-down of the complex molecule.

Separate determinations of silver have been made on tetrahedrite and galena grains in specimens of typical rich silver ores, from 50 to 100 milligrammes being secured from the individual grains by means of a sharp awl. The tetrahedrite, even under high power, was seen to be perfectly homogeneous, showing the silver to be isomorphously mixed, while the galena as usual showed spots. In a specimen from the Nettie L. mine, Ferguson, B. C., tetrahedrite grains were found to contain 7.27% silver while the galena contained but 0.23%. A similar specimen from the Silver King mine, Arizona, showed 6.06% silver for the tetrahedrite grains, while the galena contained 1.24%. Determinations on specimens from many other localities show similar results.

The microscope shows that tetrahedrite easily gives way to attacking solutions, and it may thus form the starting point for a series of reactions by which minerals richer in silver are developed. These have been observed to still further break down into native silver. In Fig. 5, from the Silver King mine, Arizona, tetrahedrite is seen with a complex system of veinlets of stromeyerite which in places enlarge to areas of considerable size. This seems to be quite a characteristic mode of break-down of argentiferous tetrahedrite, another specimen from an unknown locality in Colorado being shown in Fig. 6. The alteration has set in around quartz grains and along cracks. In Fig. 6, the complicated structure of stromeyerite due to an excess of the chalcocite molecule is faintly seen.

Tetrahedrite as observed on polished surfaces varies considerably in hardness, a condition which causes some confusion in identification because of its great variability in composition. As shown by analyses given in Dana's 'System of Mineralogy,' the copper varies from 10.8 to 44.08%; silver from a trace to 31.29%; zinc from nothing to 7.25%; and iron from 0.64 to 8.24%. Polytelite is thought to belong here, being a lead-zinc va-

riety with less than 1% of copper. In addition, the mineral grades into tennantite, the arsenical variety of fahlerz. Although it varies in hardness from 3 to 4,

scribes it as showing a purple tint when viewed side by side with chalcocite and to have sometimes a smooth and sometimes a ragged surface.<sup>7</sup>

all varieties show more relief than the silver minerals, a very important feature in identification.

Stromeyerite,  $\text{Cu}_2\text{S} \cdot \text{Ag}_2\text{S}$ , is one of the rarer ore-minerals of silver and but little regarding its characteristics or paragenesis is found in published descriptions of examination with the reflecting microscope. Murdoch de-

In the silver ores thus far studied stromeyerite has been found to present two types of occurrence. First, in veinlets and areas of considerable size, associated with tetrahedrite and doubtless derived from it. This type

<sup>7</sup>The Microscopic Determination of the Opaque Minerals, p. 117, 1916.

has already been mentioned under tetrahedrite, and is illustrated in Fig. 5 and 6. Second, as a replacement-product of bornite. In this type it appears to play much the same rôle as chalcocite in the copper ores. There are scattered residual grains of pyrite more or less completely replaced by chalcopyrite, which in its turn has altered to bornite, later to be replaced by chalcocite and stromeyerite. All of these transformations, with the exception of the first, is illustrated in Fig. 7, a photomicrograph of a polished specimen from the Silver King mine in Arizona. Pyrite though present in the specimen does not appear in the photograph. An incipient replacement of bornite in a specimen from the same locality is illustrated in Fig. 8. Replacements less often observed are galena by stromeyerite, and chalcopyrite by stromeyerite.

Microscopic investigation points toward stromeyerite being a definite molecule, probably  $\text{Cu}_2\text{S} \cdot \text{Ag}_2\text{S}$ , and not a mixture of varying amounts of copper and silver sulphides. Many samples of stromeyerite show a very complicated structure under the microscope, and this has been found to be due to an excess of the chalcocite molecule which is not isomorphously mixed with the other constituents. The structure, shown in Fig. 7, is brought out more plainly by etching with potassium cyanide solution. Stromeyerite, which appears smooth and homogeneous under the microscope, approaches the composition of the simple double salt,  $\text{Cu}_2\text{S} \cdot \text{Ag}_2\text{S}$ .

Pyrargyrite,  $3\text{Ag}_2\text{S} \cdot \text{Sb}_2\text{S}_3$ , and proustite,  $3\text{Ag}_2\text{S} \cdot \text{As}_2\text{S}_3$ , are the ruby silvers, and these rank among the most important of the ores of that metal. They are thought to have been deposited late in the history of ore deposition. Thus, Spurr describes pyrargyrite as coating crevices that cut the primary ore; it is also found in the oxidized material, and is thought to have been deposited by descending solutions.<sup>8</sup> In the same district argentite, polybasite, and stephanite are thought to be in part primary. Ransome holds that the ruby-silver minerals, together with stephanite and polybasite, are as characteristic of downward enrichment as chalcocite.<sup>9</sup> The early minerals of silver are confined mainly, if not entirely, to tetrahedrite and galena. They are therefore held to be the source of the later enriched products. Tetrahedrite seems to be the most prolific source, as shown by microscopic and chemical investigations, as well as from the fact that the rich silver minerals are most often compounds of arsenic and antimony. The results obtained from the study of polished surfaces are in accord with the earlier geological observations, at least in respect to the late deposition of these minerals. They are most frequently observed replacing sphalerite, tetrahedrite, and galena. Thus, in Fig. 2, proustite is seen in spots in argentiferous galena. In Fig. 3, pyrargyrite is observed as a microscopic veinlet following cleavage-lines in galena. Photographs might be

added in which these minerals are found replacing sphalerite and tetrahedrite in a similar manner.

Microscopic evidence is in favor of considering proustite and pyrargyrite as not isomorphous. They are frequently found mingled with great complexity, but the contact between the two minerals has always been found to be sharp and definite. The fading of one into the other, which would indicate mutual solubility, has not been observed. Fillings of cavities have been studied from Tonopah, Nevada, in which the first layer to be deposited consisted of proustite, the central portions being later filled with pyrargyrite. Pyrargyrite is more easily affected by the electric arc than proustite, and therefore greater detail may be brought out for the purposes of photographing. The ruby silvers are frequently found with spots and veinlets of native silver, resulting from the break-down of the complex silver molecule. These minerals may be distinguished from each other by micro-chemical tests as well as by simple microscopic tests of small fragments broken from the polished surface by means of a sharp point. Proustite is light red in thin fragments, while pyrargyrite is deep cherry red on the thin edges, approaching opacity in the thicker centres. The streaks are also characteristic, proustite being cherry red, while pyrargyrite is dark purplish red or brown. This test may be made on small fragments, the particles being crushed on glazed paper. These minerals may be distinguished from tetrahedrite by their inferior relief, and by their failure to respond to the micro-chemical test for copper.

Stephanite,  $5\text{Ag}_2\text{S} \cdot \text{Sb}_2\text{S}_3$ , and polybasite,  $9\text{Ag}_2\text{S} \cdot (\text{Cu}_2\text{S}) \cdot \text{Sb}_2\text{S}_3$ , are found replacing the earlier sulphides, galena and tetrahedrite, very much as in the case of the ruby silvers. They cannot be always distinguished by means of the reflecting microscope alone. Micro-chemical tests and tests on small fragments are necessary. Stephanite, like argentite, is opaque on the thinnest edges, but may be distinguished from it by its lack of sectility. Polybasite may be red on thin edges, similar to pyrargyrite, but it reacts for copper.

Argentite,  $\text{Ag}_2\text{S}$ , from the numerous descriptions of its occurrence, would seem to be either a hypogene or supergene mineral. Great masses of it were found in the upper zones of the Comstock lode. Such bonanzas are usually associated with oxidized material, and the evidence seems to be conclusive that they were deposited by supergene solutions, yet in the Comstock lode, for example, argentite has been identified at a depth of 3000 ft. below the surface.<sup>10</sup> Other examples might be cited showing evidence of its hypogene origin. In the specimens studied during this investigation, argentite is rarely found actively replacing the earlier sulphides. It is most often in small particles filling cavities in gangue, and associated with galena and with the late silver minerals as pyrargyrite, proustite, and others. On the other hand, argentite seems to yield easily to the attack of vein-solutions, and the resulting replacements and products

of break-down show interesting features. In almost every specimen the mineral is seen going over to native silver to some extent. This may appear in the form of thousands of spots of such minute size that a high power

occur in the areas of argentite, and both argentite and stromeyerite are replaced by native silver and less often by a late generation of chalcopyrite. The sectility of argentite, as observed by scratching the polished surface

is necessary to make them visible, or it may take place in the form of veinlets, or as crude segregated masses. Argentite replacing smaltite in the form of wandering veinlets is illustrated in Fig. 9, being a polished specimen from Cobalt, Ontario. Patches of stromeyerite

with a sharp point, is sufficient for identification.

Native silver is believed to have been formed ordinarily by the alteration of the earlier silver minerals, the real source of which has been mainly tetrahedrite. It has frequently been described as coating the ruby silvers,

polybasite, and others. It sometimes persists to great depths, as in the Aspen district of Colorado, where it is found crossing barite 900 ft. below the surface.<sup>11</sup> At Creede, Colorado, it is reported by Emmons to be found 1200 ft. below the surface. It has generally been assumed that silver is typically a supergene mineral, yet the compounds of silver are known to be weak, breaking down under a variety of conditions. As early as 1843 Bischof found that superheated steam was capable of reducing argentite to metallic silver, which then appeared in aborescent shapes much as in nature. Other minerals of silver treated in the same way yielded similar results.<sup>12</sup> These experiments have been repeated from time to time and modified, Moesta even finding that the reaction could take place at 100°C. From considerations of this kind, coupled with geological data, Kato thinks that native silver in certain ore deposits of Japan was deposited by hypogene solutions.<sup>13</sup> From Vogt's article on native silver at Kongsberg a similar conclusion concerning the paragenesis of some of the metal at that locality might be reached.<sup>14</sup>

In the investigation of the silver ores many cases have been observed where the complex silver minerals have broken down into native silver. The occurrence of native silver in the form of thousands of microscopic specks in stromeyerite and in argentite has been frequently observed. This is the first step in the break-down of the silver mineral, solution, transportation, and re-crystallization being necessary for the production of the delicate structure so frequently seen. Fig. 10 illustrates a veinlet of silver in an argentite specimen from Butte, Montana. A somewhat similar veinlet in stromeyerite is shown in Fig. 7. Here it expands into areas of considerable size. Fig. 11 illustrates the characteristic manner in which stromeyerite breaks down into silver and chalcocite. This is a common occurrence at the Silver King mine near Prescott, Arizona. The silver is arranged in a beautiful filiform structure, the branches of which envelop individual chalcocite grains, some of the finer filaments even extending into the cleavage-cracks of the chalcocite, thus completing the intricate design. Occasionally areas are found where the whole design is roughly oriented with reference to cleavage-directions of chalcocite. All of these features are well brought out by etching with potassium-cyanide solution, when the outline of the individual grains as well as their cleavage is made clearer. These areas grade into stromeyerite, when the native silver disappears altogether, or is confined to borders, veinlets, or clumps of rather rounded

outline. The causes which have been responsible for the filiform structure now become clear. Stromeyerite has broken down to chalcocite and silver. The chalcocite has re-crystallized into definite grains of varying size. The silver in re-crystallizing has formed around these grains, extending everywhere into the minutest cracks. Frequently the silver in re-crystallizing has extended into the cracks and surrounded grains of the gangue-minerals. Thus well-formed hexagonal crystals of quartz are found with a mirror-like film of silver. Native silver resulting from the break-down of ruby silver has been observed in specimens from Durango, Mexico, where the silver appears in much less delicate forms. In Fig. 12, spots of native silver are seen in a veinlet of tetrahedrite crossing smaltite; this is from the Cobalt district, Ontario. In similar specimens from the same locality the tetrahedrite is seen breaking down and forming ruby silver, the latter further breaking down to metallic silver.

In Fig. 13, also from the Cobalt district, silver is seen following a veinlet of niccolite in smaltite. This association calls to mind the researches of Palmer, who found niccolite to be an especially good precipitant of silver from silver sulphate solutions.<sup>15</sup> Fig. 14 shows the replacement of smaltite by silver. The euhedral crystals of smaltite embedded in silver is a characteristic feature of this class of ores. Although native silver is the natural end-product in the transformation of the various silver minerals, it may itself be the object of the further attack of supergene solutions containing chlorides or hydrogen sulphide. Its alteration to cerargyrite has been observed in specimens from the Stonewall Jackson mine near Prescott, Arizona, where grains of native silver embedded in siderite show all gradations into the chloride.

Identification of silver minerals on polished surfaces of opaque minerals with the reflecting microscope was confidently expected to enable the ore-minerals to be determined with the same degree of accuracy as has long been the case with the transparent minerals. Failure to realize this has been the cause of a frequently repeated criticism of this method. It must be admitted reluctantly that, at the present time, the chief use of the reflecting microscope in the study of ores consists in determining the relationships of the minerals rather than their identification. A good summary of the work thus far accomplished in methods of determination has been given by Murdoch.<sup>16</sup> From this it will appear that very little detailed study of the silver minerals had been made. In Murdoch's tables they are grouped according to color, hardness, and reaction with various chemicals, such as KCN, HNO<sub>3</sub>, and others. Argentite, polybasite, and stephanite are put down as grayish white; silver, dyscrasite, and huntelite as creamy white, and proustite and pyrrargyrite as bluish white. His investigations on the action

of reagents were confined mainly to the study of the tarnishing produced on the polished surfaces. I have not found this method very useful in distinguishing the silver minerals. He has employed mainly the following three methods: First, the observation of color, relief, and habit, as observed on polished surfaces; second, the study of minute fragments broken from the polished surface by a sharp point and transferred to a glass slip for examination with an ordinary microscope; and, third, by micro-chemical tests on small fragments secured in the same manner. Etching with nitric acid has been found useful in the study of argentiferous galena, the silver minerals in these being less easily attacked by this reagent; and also for bringing out structure for the purpose of photographing, especially in the case of some of the rarer silver minerals. Potassium-cyanide solution has been found especially valuable in developing the complicated structure of stromeyerite and in distinguish-

ing it from chalcocite. Hardness and color are best compared with galena, since that mineral is the one most commonly associated with the silver minerals. In this respect the tables of Murdoch have been of great value. All of the minerals, with the exception of tetrahedrite, are softer than galena, and therefore they stand out in negative relief. Even tetrahedrite, as it becomes highly argentiferous, approaches galena in hardness. The normal varieties are considerably harder. Proustite is probably the only one that can be distinguished by color alone. It has a characteristic pale bluish tint, rarely mistaken for that of other minerals. Pyrargyrite, in my opinion, is not perceptibly blue, being practically of the same tint as tetrahedrite and polybasite. It can, however, readily be distinguished from tetrahedrite when in contact with it by its inferior hardness, and from polybasite by micro-chemical tests described below.

FIG. 13. COBALT, ONTARIO

FIG. 14. COBALT, ONTARIO

ing it from chalcocite. Hardness and color are best compared with galena, since that mineral is the one most commonly associated with the silver minerals. In this respect the tables of Murdoch have been of great value. All of the minerals, with the exception of tetrahedrite, are softer than galena, and therefore they stand out in negative relief. Even tetrahedrite, as it becomes highly argentiferous, approaches galena in hardness. The normal varieties are considerably harder. Proustite is probably the only one that can be distinguished by color alone. It has a characteristic pale bluish tint, rarely mistaken for that of other minerals. Pyrargyrite, in my opinion, is not perceptibly blue, being practically of the same tint as tetrahedrite and polybasite. It can, however, readily be distinguished from tetrahedrite when in contact with it by its inferior hardness, and from polybasite by micro-chemical tests described below.

Tests on fragments are made by breaking from the polished surface minute quantities of the mineral by means of a sharp awl, transferring to a glass slip, and examining with a high-power microscope. Argentite and stephanite are opaque even on the thinnest edges. Proustite is transparent even in the thicker portions, and

water, and proceeding as outlined below. The presence of silver is learned by adding a drop of dilute chlorhydric acid. The characteristic curdy precipitate is satisfactory evidence. Comparative tests may be made on known minerals so as to be able to judge if the silver be present in large or small amounts. Copper is determined by adding potassium ferrocyanide to the slightly acid drop. The peculiar red precipitate is thoroughly characteristic of this element, and may sometimes be seen in the presence of iron if the drop of reagent be allowed to stand without rapid mixing. Some phenomenon of diffusion permits the two precipitates to be seen. These two tests are those most often required for distinguishing the silver minerals, and it has been found much more satisfactory to remove the minute amount of material required than to attempt to make the test directly on the surface. Moreover, by this method the specimen is much less damaged for further work. Having obtained the material in solution, tests may be made for other elements according to the methods outlined by Chamot in his 'Elementary Chemical Microscopy.' In the investigation of the cobalt-nickel-silver minerals the dimethylglyoxime test for nickel has been found especi-

ally useful in studying the associated minerals. Nickeliferous pyrrhotite, probably containing not more than 3% nickel, respond nicely to this test, even in the presence of the large amount of iron. The test is applied by making the drop alkaline with ammonia and adding a minute grain of the reagent. By using the solid reagent the bright red needles seem to concentrate about the solid crystal, thus making the test more delicate. The test has been found especially valuable in distinguishing fibrous iron disulphide (marcasite) from millerite.

Summarizing, it is found that stephanite and argentite are both opaque on the thinnest edges, but argentite may be distinguished by its sectility; pyrrargyrite and polybasite are each red on thin edges, but polybasite reacts for copper; polybasite and tetrahedrite may each be red on thin edges, each react for copper, but tetrahedrite is easily distinguished by its greater hardness; proustite is distinguished by its blue tint under the reflecting microscope, and its transparency and bright red color in fragments; stromeyerite, when compared with chalcocite, may be recognized by its purplish tint. It also nearly always shows a perfectly characteristic complicated structure, due to excess of the chalcocite molecule.

A delicate micro-test for arsenic and antimony for distinguishing arsenical and antimonial varieties of tetrahedrite, is greatly needed for this class of work. Berg recommends for the sulpho-salt minerals the following test: Dissolve a fragment in potassium-hydroxide solution, then add chlorhydric acid; arsenic, if present, is thrown down as a lemon-yellow precipitate; the corresponding antimony minerals give the orange sulphide.<sup>17</sup> While this works well for pure compounds, it has been found to be of limited value when applied to the complex mixtures found among this class of minerals.

RÉSUMÉ. (1) Tetrahedrite and argentiferous galena are the early sources of the rich silver minerals, even including native silver. Much of the galena has replaced tetrahedrite, so the latter mineral becomes the more important of the two. Moreover chemical tests show this mineral to be the most important source.

(2) The minerals antedating the deposition of silver in the vein are, in the order of sequence, arsenopyrite, pyrite, and sphalerite.

(3) Galena which does not show abundant evidence of later addition or enrichment has not been observed to contain more than 0.35% silver, the average of 15 specimens from rich silver-lead deposits being 0.20%. This may be present in solid solution or as sub-microscopic particles up to nearly 0.10%. Above that amount it appears as spots of definite minerals identified as tetrahedrite, or argentite, or both. Specimens of galena, with more than about 0.35% silver, show evidence of later addition of ruby silver or other rich silver minerals in the form of veinlets and other secondary features.

(4) The complicated structure of stromeyerite seen in some specimens is the result of a mixture of stromeyerite and chalcocite. Stromeyerite is believed to be a definite double salt of silver sulphide and copper sulphide. Chalcocite is probably able to hold some silver sulphide in solid solution, but the limit of solubility has not been worked out.

(5) Micro-chemical and other tests, applied on fragments secured from the polished surfaces, are considered more useful in identifying silver minerals than the etching and tarnishing methods.

(6) The order of deposition of minerals in silver deposits is outlined below. Important deviation from this order has not been observed.

#### 1. Silver-lead-zinc series:

- (1) pyrite, (2) sphalerite, (3) tetrahedrite, (4) galena, (5) ruby silver, polybasite, stephanite, (6) silver.

#### 2. Copper-silver series.

- (1) pyrite, (2) chalcopyrite, (3) bornite, (4) chalcocite, stromeyerite, and probably argentite, (5) silver. Galena when present is later than chalcopyrite.

#### 3. Cobalt-silver series:

- (1) smaltite-chloanthite, (2) niccolite, breithauptite, (3) argentite, (4) silver and bismuth.

ZINC-BLENDE from the Joplin district contains a metal known as gallium, which is now being extracted in a small way and is being sold at \$8 per dram, or about \$240 an ounce, according to George W. Waring, of Webb City, Missouri. The discovery of gallium in the zinc ore was made by a watchman at the plant of the Bartlesville Zinc Co. He noted silvery globules on some lead residue that had emerged from the process of re-distillation. He scraped off some of the globules and took them to a chemist who found that it was gallium, a very rare metal. Mr. Waring recently received about an ounce of gallium from Washington for experimentation. He describes it as having some remarkable qualities. If a drop or two is spilled into a plate it instantly scatters over the surface, covering it completely and making a better mirror than quicksilver. A few drops of weak sulphuric acid dropped on the plate will cause the metal to re-assemble into a globule. C. E. Siebenthal, of the U. S. Geological Survey, had a queer experience with gallium. By accident he touched his spectacles to the metal. It immediately covered the glasses and the aluminum frame of the spectacles fell to pieces.

BAUXITE in 1916 showed an increase in production of 43% over the previous year. Producers of metallic aluminum consumed about 300,000 tons, chemical manufacturers 80,000, and makers of abrasives and refractories 45,000 tons. For the latter purpose it is fused in the electric furnace, broken, and sized, being sold under the names of alundum, aloxite, carborundum, exolon, and lionite. The artificial abrasives made from bauxite in 1916 amounted to 30,708 tons, valued at \$2,139,230.

# American Smelting v. Bunker Hill

## ABSTRACT OF REPLY-AFFIDAVITS

By E. L. NEWHOUSE:

The Bunker Hill company knew, as Mr. Bradley's affidavit shows, that in 1905, when the contract was made, the plaintiff company did have a majority of the Coeur d'Alene ores. This is also indicated by the contract itself. This implied to them, and to all other mining men, that other smelters needing lead ore for fluxing might be compelled to bid for the smaller tonnage a smelting rate out of which they would expect to make little or no profit, or even an actual loss, in order to obtain the lead necessary as a collector in their own smelting operations. It was not contemplated that these 'fluxing' contracts, as we call them, were to determine the price of the Bunker Hill, but that the Bunker Hill rate was to be governed by a rate applicable to a majority of the tonnage of the Coeur d'Alene district, as fixed by plaintiff company, so long as it had a majority of the tonnage, and as fixed by other companies whenever the event arose that plaintiff did not receive a majority of that tonnage. This latter contingency has never arisen.

My understanding has always been that, prior to the year 1905, the Bunker Hill company did not ship any material proportion of its mine output to smelters below the grade of 30% in lead, or above the grade of 75% in lead.

My understanding at the time of the contract was that they shipped none of their product within these grades, except negligible quantities. We have not the figures of their actual shipments between those dates, and I notice that the Bunker Hill has not produced them. Schedule No. 2 of our complaint shows our information upon this subject. I believe that an actual production of the figures will show that, prior to 1905, the Bunker Hill company did not ship more than 10% of its entire shipping product in the form of a product below 30% and over 75% of lead, taking the aggregate of those two grades. Schedule No. 2 shows accurately what has been shipped since 1905, within the limitations of cut-offs. It is probable that the Bunker Hill books show ore in transit, but so far as average shipments were concerned, our schedule is correct since 1905.

I do not agree with Mr. Bradley's statement that the low-grade products, as such, are desired by near-by smelters.

The books of the Tacoma plant show, as indicated in Mr. Rust's affidavit, that the Bunker Hill company shipped to Tacoma, in the 10-year period from 1894 to 1904, substantially 1700 tons of a product of 30% lead or less, or an average of 170 tons a year. During the same period, according to our records, it did not ship to East

Helena (which was the smelter at all times nearer the Bunker Hill mine than any smelter in the United States to which they shipped) any product containing 30% lead or less.

The clause in the first paragraph of the contract, providing that the average product delivered shall be of approximately the same yearly average analysis and lead assay as the shipments made from the mines of the Bunker Hill company during any of the 12 years immediately preceding, was put in entirely for our benefit, and not at all for the benefit of the Bunker Hill. The defendant company was protected under the immediately preceding clause, providing that the product should be of a lead assay between 30% and 75%, and therefore did not need the 'average product' clause in order to enable it to deliver ore containing any percentage of lead content between those two extremes. From our standpoint, however, it was very important that the product should be of the average analysis that had theretofore prevailed. It would be a decided disadvantage to a smelter to have the ores run with a very low average or with a very high average, even though it were between the limits of the two figures named.

While I have not been able to inform myself of the exact percentage which the defendant's product averaged during the 12 years referred to, my recollection is that during those years it averaged in the fifties, and the figures of 53% in the Tacoma differential rate existed in the Tacoma contract, and as I recall, the statement was made that that was supposed to represent approximately the average shipment of the defendant company. There is no fact connected either with the milling or the smelting business, that I am aware of, which would make the 'average clause' important to the mining and milling company, but that clause is of very great importance to a smelting company, because a substantial departure from such an average as I have indicated would very greatly increase the difficulties of the smelting operation.

I note that Mr. Bradley says that the idea of inserting the 'average clause' was in order that he might be able to mix ores carrying 30% and under with ores carrying 75% and over, so as to make an intermediate product. The 'average clause' would not enable him to mix a low-grade product under 30%, and a high-grade product over 75%, any more than he could do so without it. On the contrary, the clause restricts the mining company and favors the smelter, because it compels the delivery of a product having a like average as that which it had previously delivered. As a matter of fact, however, in the ordinary practice of milling, with reference to which we made this contract, there would be very little high-grade

and very little low-grade. The high-grade would only normally occur when rich pockets in the mine were reached. This is seldom, and the tonnage is always small. No other mine in the Coeur d'Alene has ever shipped a product containing over 75% lead, except in insignificant amount.

The clause of paragraph one of the contract, that the average product delivered should be of approximately the same yearly analysis and lead assay as shipments made during any year in the 12 years preceding, like the last section of paragraph ten of the contract (which is to the effect that shipments will be made as far as practicable of approximately equal amounts during each month) was intended for the benefit of the smelting company, as it is obviously to the interest of such company to have deliveries of ores and concentrates and slimes to it made in substantially uniform quantities and of approximately uniform qualities. This is desirable in carrying on its business.

The clause upon which Mr. Bradley relies—"The mining company, in making shipments, may exercise its option as to lead content of ores, slimes and concentrates wherever the same may be shipped"—does not limit the above statement. It immediately follows the clause known as the 'Tacoma differential', which made the price of a certain amount of tonnage shipped to Tacoma vary either upward or downward from the regular price, according as the percentage of lead should be above or below 53%. The clause was put in with the intent of providing that, while we could insist upon our general average as stipulated in the first and tenth clauses of the contract, we could not control the lead contents of the individual shipments so long as the Bunker Hill was maintaining its contract average, this, because otherwise we might prevent the Bunker Hill from getting the benefit of that differential.

It must be borne in mind that the Tacoma differential provided for a different rate at Tacoma than at any other smelter, based upon the percentage of lead. On ore running less than 53% the Bunker Hill got a monetary advantage of 10 cents for every 1% of lead. Reciprocally, it lost 10 cents for every 1% of lead exceeding 53%. This differential did not apply to shipments to any of our other smelters, hence the necessity of the above clause. Otherwise, the plaintiff might have directed the Bunker Hill company to ship any individual lot, containing less than 53%, to East Helena, for example, thus depriving it of the Tacoma differential, or it might direct it to ship a lot, containing more than 53%, to Tacoma, thus imposing an additional cost upon defendant. The intent of the clause was, that the Bunker Hill although bound to produce the product called for by the other clauses of the contract, might so arrange its individual shipments as to take advantage of the Tacoma differential, and this necessitated their control of the lead content of individual shipments "wherever the same might be shipped." so long as the same were produced as the contract required. The clause above quoted, it will be noted, gives the mining company the option only in making ship-

ments. It makes no reference to *producing*, which is fully covered by other clauses.

Referring to paragraph nine of the answer, I note that the tonnage of the Hercules is stated to be 1500 tons per month. This was true in the year 1905, but that mine rapidly increased its tonnage until in 1912 it was shipping approximately 5000 tons per month and in 1914 over 7000 tons per month.

In some of the affidavits of defendant reference is made to the purchase by plaintiff of lead ores from Missouri mines. The lead ores of Missouri contained practically nothing but lead, and no silver. The method of treating them is therefore entirely different from that of the silver-lead ores of the Coeur d'Alene district. They are never mixed in with dry ores containing gold and silver and cannot be used as a collector in the treatment of these ores for the reason that to mix them with these ores necessitates then the further refining of the entire product of the lead mine, which is a very material additional expense. It is true that we have increased the output of our Missouri mines to take care of lead sales demands, but this increase has reached its limit and if we should now lose the Bunker Hill ore we would be hampered in our lead sales department in the manner shown in our opening affidavits. Moreover, the production from the Missouri mines will rapidly fall off when lead goes below 7 cents a pound, since much of that production comes from ores which can only be mined and treated profitably with a very high-priced lead.

Referring to that portion of Mr. Bradley's affidavit in which he mentioned as other minerals in the Bunker Hill ore, "salts of silver, copper, zinc, antimony, iron, tin, nickel, cobalt, cadmium, arsenic, titanium, phosphorus, aluminum, manganese, and magnesium, etc," I will say that while some of these minerals are found theoretically in the laboratory by the most minute chemical analysis, they are not found in what are known as commercial quantities and are not found in quantities now exceeding the quantities existing at the time of making the contract.

Referring to the lead smelters standing ready until June 1915 to buy ore when it was prepared for shipment, I know of no fact or circumstance whereby the situation on or since June 1915 is different in this regard to the situation prior to that date, excepting only that owing to the war risks above described these smelters now are asking higher rates than they did before.

Mr. Bradley mentions a number of smelting plants and states that plaintiff is now in control of all but two of said smelting plants. The two plants there listed not controlled by plaintiff are those of the Pennsylvania Smelting Co., at Carnegie, Pennsylvania, and the Ohio & Colorado Smelting & Refining Co., at Salida, Colorado. The other plants there listed were acquired by plaintiff at or before the time of the execution of the contract and there has been no change in that respect since that date, so far as concerns the control of those companies. Since the making of that contract additional lead smelters have been constructed by other companies, as already pointed out. All of the plants controlled by plaintiff have, dur-

ing all said times, been managed with equal honesty and fair dealing, so far as I have ever been informed, without discrimination either as between themselves or as to mining companies.

Mr. Bradley intimates that the art of concentrating can be developed to the extent of producing a high concentrate and thus avoiding metal losses. It is not true that high concentration reduces losses. Mr. Larson carries this a step further and proposes by a hydro-metallurgical chemico-electrical process to abolish smelting altogether. The problems suggested by these contentions have not as yet arisen; such commercial methods have not as yet been developed, and they do not now constitute any point at controversy between these parties.

At the time the contract was made I by no means considered that defendant had less than five years ore in reserve, or that its active life would be limited by any such period. My knowledge of the Coeur d'Alene district and my investigations led me to believe that a 25-year contract for defendant's output would be valuable and that ore would be delivered under it for that full term—assuming, of course, that defendant should continue mining at the rate theretofore and since prevailing.

Referring to Mr. Bradley's statement as to the understanding reached in the negotiations early in March 1905, I do not deem it important to set out here the different conclusions reached at different times in those negotiations, I consider that the contract speaks for itself and that nothing would be gained by stating the conclusions or views of the parties other than the language finally embodied in it.

In connection with Mr. Bradley's reference to the purchase of the Everett smelter by the Federal Mining & Smelting Co., one of the subsidiary companies of plaintiff, it should be remembered that the plaintiff purchased the Everett smelter from the Federal company in 1903, and the ownership of that smelter by plaintiff was well known to defendant prior to and during the year 1905. The Federal company in 1903 made an arrangement with plaintiff similar to that which defendant made with plaintiff in 1905, namely, to sell its smelter and received from plaintiff at the same time an ore-purchase or smelting contract. I have already stated that the only effect of inserting in the contract a clause referring to the shipment of from 27 to 37 tons of metallic lead per day to Tacoma was to give defendant a special price and treatment charge on that quantity of product, there being corresponding provisions to that extent in the then existing contract between defendant and the Tacoma company. That full advantage has been received by the defendant from the making of the contract to the present day.

The suggestion as to the idea of providing for the same yearly average analysis and lead-assay as to ore previously shipped is not at all in accordance with my understanding. We have always acted on the understanding that this was for the protection of the plaintiff and was to assure it a continuation by the defendant of a product averaging as it had theretofore averaged and a product

of substantially the same grade and character. So far as concerns Mr. Bradley's claim that a low-grade product might be shipped to Tacoma under that clause, I think it is sufficient to say that when the point arose as to the possibility of shipment of low-grade in 1906, we elected to purchase the entire low-grade product of defendant at the Tacoma rates and have ever since continued ready to do so.

Referring to the contracts of defendant outstanding in March 1905, I call attention to the terms of our contracts in relation thereto. The reference in Mr. Bradley's affidavit to his desire, expressed in the correspondence, to ship crude ore to Tacoma, and the position of the plaintiff with regard thereto, is misleading. Prior to the time that we exercised our option to take both the defendant's high and low-grade products, it is true that under the contract crude ore shipped to Tacoma would have to run at least 30% lead. After the exercise of our option above-mentioned there was no longer any question but that we were entitled to receive defendant's entire output.

Mr. Bradley recognizes that from 1906 to 1915 the Tacoma company met competitive bids on the high and low-grade products. The fact is we have met them up until not only 1915 but since and have been and are now willing to meet them. It should be borne in mind, however, that the usual operation of defendant's plant produces a product mostly within the normal grade containing from 30 to 75% lead and whenever and wherever that grade of product is produced, whether in its mining, milling, or smelting operations, the plaintiff is entitled to it at the rate prescribed for normal grade. The defendant has no right to re-treat the product of that character so that it will be removed out of the normal grade and put into high-grade. Plaintiff has never recognized the propriety of any such practice.

The examination of defendant's mine referred to by Mr. Bradley, made by Mr. Pope Yeatman, was in no way related to the dealings between the parties to this action.

Mr. Bradley says that he claimed that in 1910 plaintiff was not purchasing a majority of Coeur d'Alene ores for the reason that we should not count the ores to the Selby and Tacoma smelters. Mr. Bradley knew that we owned and we have at all times since owned and controlled all of the stock of both these smelters. He always dealt with these smelters as American Smelting & Refining plants and shipments were made to each of them as plaintiff directed, these plants, like all our other plants, being managed and operated by plaintiff.

Mr. Bradley says that they let contracts to their architects for their smelter as early as September 1915, while Mr. Brush did not write his letter notifying them of our position until November 1915. We did not know that they had let any kind of a contract at the time the letter was written. We still understood that they had the matter of constructing a smelter under advisement and it was not until February 1916 that they finally notified us that they had determined to construct a smelter. Actual construction was not begun until March or April 1916.

I note that Mr. Bradley states that in defendant's new smelter they are smelting lead ores, some of which carry 8% zinc. Not knowing of the percentage of the ores smelted carrying this percentage of zinc, no conclusions can be based on that statement except that I do know that the Bunker Hill ores do not average 8% zinc, while the Hecla, Sierra Nevada, and other ores (which the Bunker Hill has contracted to smelt) do run higher in zinc. Hence, I conclude that the defendant is diluting the other ores with the ores from the Bunker Hill mine. In my judgment, Kellogg is by no means a logical point for a lead-smelting plant. We ourselves examined the Coeur d'Alene for a point at which to erect a smelter and determined that a smelter at that location was not warranted because of the absence of dry-ore supply, increased cost of coke, and lack of limestone, and the Bunker Hill people themselves were in great doubt whether to locate their new smelter at Kellogg or at tide-water.

Mr. Bradley names a number of mines that, he says, are new mines. These are old mines, with the exception of the Interstate Callahan, which is principally a zinc mine. The Bunker Hill company itself owns practically all the stock of the Sierra Nevada, the stock of the Caledonia, and other companies either directly or through Mr. Bradley, Mr. Easton, or Mr. Folsom, and has a lease on the Ontario. The Marsh mine is not a profitable mine; the Green Hill Cleveland is a mere extension of the orebody of one of the Federal mines that has been operated for over 20 years.

In answer to further statements by Mr. Bradley, I would say that neither plaintiff nor any of its subsidiary companies has given to the Federal company, or to the Stewart Mining Co., or to any other mining company in the Coeur d'Alene any better rate or terms than those which are now given to defendant under the contract. For a certain kind of low-grade ore, we are giving a special rate to the Federal company, but we have offered the same rate to the defendant on the same character of product. The defendant attempted shipping that class of ore and decided that it was not as profitable as the method followed theretofore and hence has not availed itself since of the method thus offered and tried. I desire further to call attention to the fact that the freight-rate from Kellogg to Tacoma at the time of the making of the contract was \$4 and that it has since remained at that rate.

---

By F. W. BRADLEY:

Replying to the reply affidavit of Edgar L. Newhouse: I have no accurate information as to the exact tonnage of Coeur d'Alene ores now being produced, but I do know that the tonnage varies from day to day and my best information is that the plaintiff herein has not been and is not now purchasing a majority of Coeur d'Alene ores of the general character referred to in said contract.

Defendant has never owned or leased the mining claims of the Sierra Nevada Co. For several years prior to 1910

defendant owned about 10% of the capital stock of said Sierra Nevada Co. and during the year 1910 acquired an additional 68% of said company from the Federal Mining & Smelting Co., which latter company is controlled by plaintiff. The purchase of said Sierra Nevada stock was made with the knowledge and consent of the plaintiff's officers, who had also knowledge at that time of the ownership by defendant of an additional 10%. In 1912 while plaintiff was negotiating for the purchase of the Sierra Nevada ores plaintiff made the point that such ores should be shipped under the Bunker Hill contract with Tacoma because defendant owned the control of said Sierra Nevada Co. Defendant, through its manager Mr. Easton, resisted this contention, whereupon plaintiff yielded and entered into a contract for Sierra Nevada ores so that there was no legitimate controversy concerning said ores subsequent to that time. Subsequent to 1910 defendant has acquired from time to time certain shares of the Sierra Nevada Co., but it has never owned the entire capital stock of said company and it would be an obvious fraud upon the independent owners of stock of the Sierra Nevada Co. (who do not desire to sell their stock) to dispose of the ores of said company under defendant's contract with Tacoma when more favorable rates prevail.

The form of resolution of the Board of Trustees of the Tacoma company passed in 1906 did not purport to exercise and was not treated by the parties as exercising an option for either the high or low-grade products of the defendant company except for a limited time. The resolution was subsequently disregarded by the officers of the Tacoma company. It was never understood by the Bunker Hill company that it should continue to treat its product substantially as it had treated its ores for 12 years prior to making said contract. On the contrary, it was at all times understood in all the dealings that the Bunker Hill company should have the right to make such grade of product as it saw fit.

Iron middlings are not distinguishable from other low-grade concentrates.

My understanding has always been that the stock of the Tacoma Smelting Co. and of the Selby Smelting Co. was owned by the American Smelters Securities Co. and that a majority of the common stock of the latter company was owned by the plaintiff company. From the published facts I have known that the preferred stock of the American Smelters Securities Co. exceeded the common stock and was not owned by the American Smelting & Refining Co. The common stock of the Securities company carried a voting power, so that the American Smelting & Refining Co. might elect the officers of the Securities company, but it has always been my understanding that the larger portion of the money invested in the Securities company was invested by the public. This is still my understanding.

It is not true that the Bunker Hill company owns practically all of the stock of the Sierra Nevada Co. It is not true that it owns practically all of the stock of the Caledonia company either directly or otherwise, and it

is not true that the Bunker Hill company either directly or indirectly has ever held a lease on the Ontario.

Replying to the reply affidavit of W. R. Rust:

It is not true that the stockholders of the Bunker Hill company ever controlled the three Alaska companies described in the affidavit of said Rust or that they ever owned a majority of the stock of either of said companies. Said W. R. Rust in a letter to me dated February 1, 1905, reported "since May last we (Tacoma Smelting) have been earning at the rate of \$553,334.40 per year."

The statement contained in said affidavit to the effect that a contract was drawn up between Baruch and the stockholders of the Tacoma Smelting Co. and signed by all individual stockholders of the Tacoma company prior to the meeting in San Francisco is not true. The above referred to contract was solicited in New York City without my presence and without my knowledge, and was drawn up in New York City on January 9, 1905, between B. M. Baruch and W. R. Rust; and it was made a condition of this Baruch deal that 25-year contracts be made for the entire output of the Douglas Island and Bunker Hill & Sullivan mines. On January 23, 1905, Mr. Rust presented his said contract with Mr. Baruch to William H. Crocker (director and treasurer of the defendant) and myself, in San Francisco, and asked us to consent to the deal on behalf of the Bunker Hill company. We refused to do so unless the deal be modified so as to guarantee the Bunker Hill its then existing freight and treatment rates, and in addition thereto all concessions and betterments that might thereafter be granted Coeur d'Alene mines by the smelters. The defendant's position in the matter was wired to New York City the same day, and on February 20, 1905, Mr. Rust again appeared in San Francisco, and this time with Mr. Baruch, to resume the negotiations. I never signed any Baruch deal contract on behalf of the defendant prior to signing the contract.

It is not true as stated by Mr. Rust that it was ever understood by the defendant Bunker Hill company, or by me, that said company should after the consummation of contract continue to treat its product substantially in the same manner as it had theretofore treated its products from the mine. It is true that this contention was made by Mr. Rust after the contract was entered into, to wit: About the first of the year 1906, and Judge Lindley was asked to give his opinion upon the matter and he agreed with me that we had the right to control the grade of our product wherever the same might be shipped. Rust consulted other counsel and he advised that they agreed with this construction. Subsequent to the resolution of the Tacoma company the said Rust and said Tacoma company repeatedly treated the same as having expired.

The so-called iron middling is concentrate containing less than 30% in lead; is produced in the concentrating plants of the company and is not essentially different from any other Bunker Hill concentrate containing an equal percentage in lead.

It is not true that it has been the customary practice for the defendant before shipping any of its product elsewhere to inform plaintiff that it had a bid therefor or the nature of such bid or to consult plaintiff with reference thereto.

The closing of the Tacoma lead smelter did materially injure the Bunker Hill company, because there was one less lead smelter in need of lead ore, and consequently there was more lead ore for other lead smelters. Poorer terms would naturally be offered by the smelting companies when there was less demand for lead ores.

It is not true, as stated by Mr. Rust, that after June 1, 1915, the Tacoma company demanded merely half of the price above \$4.10 per hundred for lead. The Tacoma company also demanded 10% of the price up to \$4.10 per hundred pounds on the theory that plaintiff herein could keep up the price of lead and it and its associated companies were entitled to be rewarded. The average price of lead had not been \$4.10 per hundred pounds up to 1905; but on the contrary had been \$5 per hundred pounds.

IN PERU the Cerro de Pasco Mining Co., an American organization, and the Backus & Johnston Mining Co., which is now controlled by the former, produced about 95% of the total output of fine copper during 1916, the total production being estimated at 41,625 long tons with a value of \$25,928,712. Of this output the Cerro de Pasco Co. produced 31,250 tons, and the Backus & Johnston Co. 8,638, a total of 39,888. It was shipped in the form of copper bars. The production of Peruvian copper in long tons during the last five years was as follows: In 1912, 27,400; in 1913, 27,500; in 1914, 25,070; in 1915, 31,890; and in 1916, 41,625. The indications are that the 1917 output will be considerably higher than in any previous year.

SANTA EULALIA, the famous silver district situated 14 miles east-southeast from the city of Chihuahua, Mexico, was known as early as 1591, but the first important discoveries were made in 1702. From 1705 to 1790 it produced \$130,748,314, being at the rate of \$1,538,100 per annum. From that time forward for 94 years the annual output averaged only \$23,900. During the last 15 years the production of silver ore from the mines of Santa Eulalia has greatly increased through the efforts of American companies. Part of the ore is smelted by the American Smelting & Refining Co. at its Chihuahua plant, and part is shipped to the smelter at El Paso.

THE HOMESTAKE MINE in South Dakota produced from 1875 to the end of 1916 a total of \$148,141,385, of which amount \$37,826,116 was paid to the stockholders in dividends. During the last five years the mine has been worked at a greater profit than ever before. The assay-value of the ore last year was \$4.08 per ton. This is by no means the lowest average value, however. In 1911 the ore milled contained only \$3.57 per ton, and in that year the profits distributed were \$1,310,400.

## Licenses for Use of Explosives

Any person in the United States found with explosives in his possession after November 15, and who does not have a license issued by the Federal government showing the purpose for which the explosives are to be used, will be at once arrested and fined up to \$5000 or sent to prison for one year. If the circumstances warrant, violators of this order may be fined \$5000 and in addition given the one year in prison. This is the principal clause in a war measure passed by the last Congress which is now being put into effect by the Bureau of Mines. Francis S. Peabody, of Chicago, a well-known coal-operator familiar with the use of explosives, large amounts of which are used in the coal-mining industry, has been appointed by the Secretary of the Interior to act as assistant to the director of the Bureau of Mines in the enforcement of the law. The director is empowered to utilize the services of all United States officers and all police officers of the States, including the city-police forces, county sheriffs, deputies, constables, and all officers in any way charged with police duties. Persons apprehended in plots to blow up factories and bridges will be turned over to the authorities for prosecution under Federal or State laws. Most States have specially severe punishments for these crimes. New York has an extreme penalty of 25 years imprisonment for the placing of dynamite with intent to blow up property. The penalty provided in this Federal war measure is merely to cover the illegal possession of explosives. The law provides that everyone who handles explosives must have a license. The manufacturer, the importer, and the exporter must have licenses issued by the Bureau of Mines in Washington. The seller of explosives and the purchaser of explosives must also have licenses, these to be issued generally by county clerks, or other local officers who are authorized to administer oaths. There will be at least one licensing officer in each county, and more agents will be designated if the county is sufficiently large to warrant it. If a State has laws providing for a system of licensing persons manufacturing, storing, selling, or using explosives, the State officials authorized to issue such State licenses shall be designated as federal licensing-agents; also city officials qualified to issue city-explosives licenses will be given authority to issue federal licenses. A federal license will not relieve any person from securing licenses required under State laws and local ordinances. In each State there will be appointed a State explosive inspector, who will represent the Bureau of Mines in the administration of the law within the State. Only citizens of the United States or of countries friendly to the United States and the Allies may so obtain licenses. Contractors, mining companies, quarrymen, and others using large quantities of explosives, which are handled by employees, may issue explosives to their employees only through those employees holding

a license, called a foreman's license. The purchaser of dynamite, in obtaining a license, must state definitely what the explosive is to be used for, and will be held accountable for its use as stated, and the return of any explosives that may be left. With the strict enforcement of this law, the Federal authorities hope to prevent explosives falling into the hands of evilly-disposed persons and to put a stop to further dynamite plots.

## Active Nitrogen

\*It has been known for a long time that near-vacuum tubes frequently show luminosity of the contained gas after discharge of electricity through the tube. In the case of air R. J. Strutt found that this is due to a phosphorescent combustion occurring between nitric oxide and ozone, both formed during the discharge. He also found that other phosphorescent combustions are observed in ozone, notably of sulphur, sulphuretted hydrogen, acetylene, and iodine. With moderate discharge of electricity it was at first supposed that pure nitrogen gave no afterglow, but when a jar-discharge was used with a spark-gap the glow was readily obtained. In order to examine the properties of the gas while showing this phenomenon, the vacuum tube through which the discharge was passed was connected with an observation vessel, and a current of gas was drawn through it by a powerful air-pump. One remarkable effect on the appearance of the glow is produced by a change of temperature. If a long tube, through which a stream of glowing nitrogen passes, is moderately heated the glow is locally extinguished, but the luminosity is recovered as the gas passes into the cooler parts of the tube. If, on the other hand, the gas be led through a tube immersed in liquid air, it glows with increased brilliancy where it approaches the liquid air, though the luminosity is finally extinguished when it reaches the coldest part of the tube.

The glowing nitrogen has remarkable chemical properties. It combines with common phosphorus, at the same time producing much red phosphorus. In this behavior it resembles the halogens, chlorine, bromine, and iodine. It also combines with sodium, with mercury, and some other metals, in each case developing the line-spectrum of the metal concerned. It attacks nitric oxide with the formation of nitrogen peroxide, a more highly oxidized substance. Active nitrogen also attacks mercury, forming a compound that explodes when moderately heated. It appears that the phosphorescent nitrogen does not owe its activity to a state of condensation corresponding with that of ozone, the molecule of which consists of three atoms,  $O_3$ , the instability of the molecule being due chiefly to the tendency to the production of the more stable molecule which contains only two atoms,  $O_2$ . Active nitrogen appears to consist of separate atoms of the element.

\*W. A. Tilden, 'Chemical Discoveries and Inventions of the 20th Century.'

# REVIEW OF MINING

## LORDSBURG, NEW MEXICO

THE 85.—LAWRENCE.—UNITED STATES COPPER.

It is estimated that the production of the Lordsburg mining district for 1917 will total \$2,250,000. The bulk of this production is from the mines of the 85 Mining Co. and the Lawrence Mining Co., operators of the Bonney mine. Lessees have shipped the balance of the ore in the district, there being no other operating and shipping companies.—The 85 Extension Mining Co. was a failure; it has given up its option on the Atwood mines and is in a bad financial condition.—The Green King mine also has proved to be one of little merit. An Ingersoll-Rand air-compressor and equipment was erected at the mine, but the returns from ore shipped would not justify operations. The mine has been closed-down and the equip-

THE 85 MINING CAMP

ment will be sold to miners in the Burro Mountain district.—The 85 Mining Co. has had one of its most successful years and is rushing the construction of its new concentration plant. Part of the machinery is now on the ground and more is coming in daily. The excavation work is completed. The mill will have a daily capacity of 400 tons and will treat custom ore besides the 85 company output. The plant should be in operation by next March.—At the Bonney mine the heavy flow of water has been adequately handled and development work is progressing. The output of the Bonney mine this year has been about 1200 tons per month. The ore averages \$23 per ton. Considerable development work has been done by the Lawrence Mining Co., the No. 2 and 3 shafts have been connected and the No. 2 shaft extended to the 400-ft. level.—The Last Chance mine is operated now by Fairly, Wells & Sholly under lease and option from the El Centro Mining Co. Two carloads of high-grade gold and silver ore has been shipped and mining continues on a larger scale.—The Nelly Bly is still shipping but may close down before many months.—At Lee's Peak the Octo Mining Co. has been getting out some lead ore but no work to speak of has been done during the year.—The Atwood mine has been taken over by a company to be known as the South Chino Copper Co., recently organized in Boston, Massachusetts, and incorporated in Arizona. Berger and Russell of Globe, Arizona,

are the principal operators, with Boston interests assisting. The company is operating steadily on the Atwood shaft and taking out fair ore.—At Santa Rita it is reported the Ivanhoe will be sold to Eastern interests. Owens and Kiner now are leasing this mine from the Hermosa Copper Co. of San Francisco. The Lucky Bill mine near the Ivanhoe at Vanadium is shipping steadily and J. B. Gilchrist is developing some property in the neighborhood with a three-compartment shaft.—The United States Copper Co. at Hanover has been revived with the purchase of interests in the company by C. B. Manville of the Johns-Manville Co. It is said to be in good condition for operating.—At Steeple Rock mining is quiet. The Carlisle Mines Co. has practically closed, and the men have left camp. It is announced that the company will be reorganized for the continuance of operations at the Carlisle. The company has spent a great deal of money on this property. The Jim Crow mine has also been turned back to the owners by the La Jara Mining Co. George Utter is continuing work on this property. Other operators in the Steeple Rock region are going ahead with their development. The close-down of the two big companies does not seem to have had any effect upon the optimism of the other owners and operators.—Gage, in Luna county, is again revived and a large number of people are employed at the old Victorio mines by the Gage Mining Co. A company from Louisiana is operating the property and meeting with success.—In Lincoln county mill equipment and amalgamating machinery has been received at the Vera Cruz mine (Carrizozo). Preparations are being made for extensive operations of the property.—Oil excitement is prevailing in numerous parts of the State, especially in the Pecos valley at Dayton and Carlsbad.—Labor conditions are excellent and no trouble has occurred in any of the metal mines. There was some I. W. W. agitation in the coal mines in the northern part of the State but the metal mines have been most fortunate this year.

— BY THE EDITOR FOR THE LANS OCEAN

## MONTERREY, MEXICO

SETTLEMENT OF CLAIMS.—A. S. & R. Co.

As soon as President Carranza announces the appointment of the commission to pass upon the claims for losses and damages to property as well as for personal injuries and deaths incurred during the long revolutionary period, the work of adjudicating the thousands of claims that are ready for filing will be started. Under the decree issued by the President the commission will have three years in which to complete its work. Where the Mexican government is to get the money to pay the enormous claims that are held against it by Americans and other foreigners no one seems to know. It is roughly estimated that the bills of American interests alone aggregate upward of two hundred million dollars gold. This sum is made up chiefly of losses and damages to mines, smelters, manufacturing plants, railroads, and plantations. British interests have suffered about fifty million dollars losses and damages. Besides these foreign-owned properties, there are many millions of dollars of domestic-owned holdings, belonging to non-combatants which the Government will be asked to settle. According to authoritative information from the City of Mexico, the Carranza government will

seek to evade being held financially responsible for losses and damages that were inflicted by opposing or preceding warring forces. In other words, the Government will refuse to consider claims that were incurred during the regimes of Madero, Huerta, Diaz, or Villa. One of the requirements of the recent decree of President Carranza is that certificates of citizenship must be attached to all claims of foreigners filed with the commission.

The smelters which were recently placed in operation are meeting with difficulty in securing shipments of ore from the different mining camps owing to the renewed activity of groups of revolutionists and bandits. The American Smelting & Refining Co. will be forced to again close-down its smelters at Monterrey, Aguas Calientes, and Matehuala unless conditions improve. This company has ceased the construction and repair work that was in progress upon its smelter at Chihuahua, and all of the American employees of that plant have been moved to the United States to avoid the possibilities of their falling into the hands of Villa.

## PACKARD, NEVADA

ROCHESTER COMBINED.—NEVADA PACKARD.

The Rochester Combined Mines Co., at Packard, has closed-down after a short but spectacular existence. Last December the company bought and optioned about 90 claims lying between Packard and Rochester, upon which practically no development work had been done, and immediately began the erection of a 350-ton mill. The mill is now nearly completed at a cost of over \$300,000, but practically no ore has been developed in the mine. M. R. Thurston, now in charge of the Kanrohat mine near Round Mountain, recently took charge of the Combined company, but resigned as soon as he recognized the true conditions. The crew of over 100 men was discharged and the mill left in charge of a watchman. There is little chance of the mill ever being completed. Some ore has been opened on the extension of the Packard orebody near the Happy Jack shaft, and intelligent work might develop enough to justify a 50-ton mill. The company also located a town-site, selling lots to its employees and to business men, many of whom erected substantial cottages in the belief that the town would be a permanent one. The stock was floated by Louis A. Friedman, president of the Rochester Mines Co. The latter company continues to produce about 200 tons per day, most of which comes from the 800 and 900-ft. levels. Excellent ore is reported to have been developed by a winze sunk to the 1100-ft. level.—The Nevada Packard mill is handling slightly more than 100 tons daily of ore running about \$8 per ton. Grading for the mill addition is nearly completed and erection of vats will start within a few days. On the surface ore, where the silver was contained in cyrargyrite, the mill made the remarkable extraction of 94 to 95%, but when the milling of sulphide ore began the extraction dropped to 87.5%. Tests have shown that the reduced extraction was due to the period of agitation being too short. Two 35 by 15-ft. agitators were purchased from the dismantled Buckhorn Mines Co. mill and will be added to give an uninterrupted agitation with change of solution, followed by the present counter-current treatment and filtration. The output will probably be increased to 115 tons per day. Sinking from mill-level will commence as soon as the necessary equipment arrives. Some rich ore has been opened in a previously unprospected block of ground between the contact orebodies and the caved C adit workings. The open-cuts are still furnishing a large tonnage.—Several thousand tons of low-grade ore from the Nenzel Crown Point and other Rochester properties are awaiting shipment to the smelter at Kennett, California, but are delayed by the condition of the chronic shut-down afflicting the Nevada Short Line railway. The smelting company has done much to revive many of the smaller properties of Ne-

vada that are in a position to supply silicious ores. It is understood that only a nominal treatment charge is made.—The old camps of Mill City and Imlay on the Southern Pacific railroad between Lovelock and Winnemucca are again active. At the former camp, the long-deserted mill is being remodeled by Wilson and Johnson. Several mines are making small shipments of tungsten ore to the mill at Toulon, which is running close to capacity. The Imlay mine, at Imlay, a silver producer of the early days, is again producing, after a shut-down of many years.

## MAMMOTH, UTAH

BINGHAM.—ORE SHIPMENTS.—KNIGHT DRAINAGE TUNNEL.

Bingham Mines Co. and its subsidiaries, Eagle & Blue Bell and the Victoria Consolidated, earned \$23,000 in October, against \$13,385 in September. The poor showing made in the last two months was due to the smelter embargo on lead ores. To offset this situation shipments of dry ore carrying chiefly copper and silver are being increased. In 10 months the three companies earned \$747,500 as compared with \$310,075 in the entire year 1916. A new strike has been made on the 1875-ft. level at the Eagle & Blue Bell.—The assessment of 1¢. per share, delinquent December 27, sales day January 15, has been levied by the Bullion Hill Mining Co., at Chloride, Arizona, controlled by the Knight interests.—The Cedar Talisman, near Milford, now being worked under lease by H. S. Joseph, is producing ore of an average value of 14% lead and 14 oz. silver.—A depth of 1975 ft. has been attained in the No. 1 shaft of the Iron Blossom Mining Co. This shaft will be sunk to the 2100-ft. level, and from there prospecting drifts will be sent out.—The ore shipments from the Tintic district during the week ended November 30 totaled 183 cars. The following are the shippers:

	Cars		Cars
Dragon .....	37	Gold Chain .....	10
Mammoth .....	24	Tintic Standard .....	8
Iron Blossom .....	21	Chief Con. ....	5
Centennial Eureka .....	14	Empire Mines .....	5
Eagle & Blue Bell.....	14	Ridge & Valley.....	5
Colorado .....	13	Other mines .....	17
Grand Central .....	10		

The Knight Drain Co. is progressing favorably. The company has purchased hundreds of claims which will be cut by the tunnel. The tunnel will tap the big mines at the south end at a depth of not less than 2000 ft. If it makes it possible to operate these mines below the water-level the company will receive a royalty on all ores shipped.

## PLATTEVILLE, WISCONSIN

THE ZINC AND LEAD SITUATION.—LUCKY FIVE—WISCONSIN ZINC.

—FRONTIER.

Complete returns from the zinc-lead districts of Wisconsin for the week ended November 24 show good results. The setbacks previously experienced on account of sleet storms were entirely overcome and roads from outlying mines to railway track showed much improvement, making ore deliveries less difficult. The gross recovery of zinc concentrate from all mines for the week totaled 5251 tons, against an even 4200 tons reported for the week preceding. At the same time there was a correspondingly generous contribution of raw ore to zinc refineries in the field, 102 cars, totaling 4051 tons, going this way. Some of the refining-plants that had been out of commission resumed operations, running on current production so that the reserve in the field, conservatively estimated at several thousand tons, was in no wise diminished during the week. Shipments of mine-run to smelter direct was shown in heavier volume, mainly through the aggressive buying

tactics of the Grasselli Chemical Co. In addition the chemical company cut in on high-grade ore from refineries making the best record on straight out and out buying of any firm represented in the field. Refiners improved their time as well, although all finished ore ready for prompt delivery was not permitted to reach track; 41 cars, or 1673 tons, clearing for the week. This with mine-run to smelters made the total net deliveries out of the field for the week 2886 tons, a fairly respectable showing, all adverse conditions of labor and operating costs considered. Prices for zinc ore remained unchanged, the base per ton standing at \$62 for top grade and 60%, with the range down to \$57 per ton, base, on second and medium-grade ores. Lower grades evidently were in good demand as shipments of ore from independents to refiners sold on open market, and quotations were much heavier than in several weeks.

Lead-ore producers held determinedly to their sworn purpose not to sell any ore, having followed this programme for six consecutive weeks. Offerings of \$75 per ton for 80% ore held firm, but sellers declare not a pound of lead ore will be offered for sale until the ground lost, when lead ore declined from \$80 to \$60 per ton, has been fully recovered. Evidence has been furnished that the deed has been suited to the word for not a car of lead ore has cleared from the field upon which current market quotations apply for six weeks. Production shows marked improvement of late, many of the larger operating groups running into rich ground from which recoveries of ore have been uniform and heavier than usual. The reserve in the field after careful tabulation shows about 2000 tons of choice lead concentrate snugly tucked away in bins. Operators declare this reserve will be permitted to increase until it may be seen what action the Government will take with regard to both zinc and lead before making final decisions.—Prices on iron pyrites showed no change whatsoever and refiners displayed no enthusiasm in marketing ores, a scarcity of cars for prompt loading making the shipment of zinc ore preferable. Fine from separating plants cleared exclusively, shipments averaging about 500 tons per week.—The carbonate-zinc ore miners of the northern districts of the field found little in current quotations to tempt increased operations and shipments were confined to a single car. Usually at this time of the year scores of small operating concerns turn their entire attention to underground work, but quite the contrary is true this season, miners finding little encouragement this year in the offerings held out for this class of ore. Labor is very scarce and unless mining is found profitable, crews are disbanded, quickly scattering to other sections of the field where the wages paid are now the highest ever known in this field.

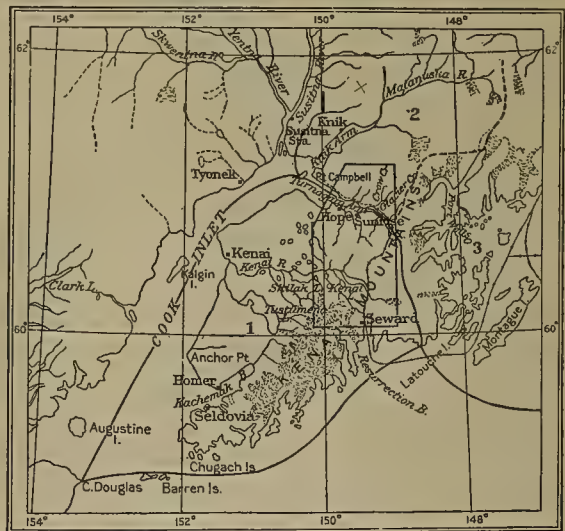

The week was crowded with events of importance at all points in the field. In the Dodgeville district the surface rig of the Lucky-Five Mining Co., valued at \$25,000, was entirely destroyed by fire. Explosions, quickly followed by fire breaking out at several points in the concentrator, leave no doubt the fire was of incendiary origin. The plant was partly covered against loss and will be re-built without delay. In the Linden district three new milling plants will be constructed, one now being under way. The other two will be erected on the Vial mine and the Treloar-Kickapoo leases. At Platteville foundations were run for a new concentrator on the New Rose mine. A new power and mining plant is also being erected for the Old Mexico Mining Co. of Chicago. The Wisconsin Zinc Co. is well along with a new 200-ton mill on the Copeland mine, in the Shullsburg district. At New Diggings the Chicago & Northwestern railway has completed a branch from its main line to the very doors of the big Skinner Separating works, incidentally giving quick and easy access to several large zinc-ore producers upon the immediate right of way. This branch will prove one of the biggest boons offered to zinc-mining men in this field. The Frontier Mining Co. has

developed a wonderful producer in the Grotkin mine where two distinct veins have been determined through underground development. Two low-grade producers, the Hird mines No. 3 and 4, have been shut-down until operating and marketing conditions offer better returns. The C. S. & H. Mining Co. of Cuba City, recently equipped and set in operation, is developing into a heavy producer, deliveries already going four cars weekly. The Connecting Link Mining Co., recently incorporated for \$60,000, has two shafts bottomed in ore, and at a recent meeting of stockholders it was elected to provide a modern surface plant. A rich strike of zinc ore was made in this same district during the week on the Hercules Mining Co. lease, the drillers worming their way through 16 ft. of highly mineralized areas. The company has been incorporated for \$100,000; a power and milling plant will be provided without delay.—Two new producers are expected to materialize in the Hazel Green district, one at the old Jefferson mine for the Vinegar Hill Zinc Co. and the other at the McMillan Zinc Co., fully equipped with a new power and concentrating establishment. Both are in full operating order and shipments are expected soon.

## ANCHORAGE, ALASKA

### PROGRESS IN THE WILLOW CREEK DISTRICT.

It may roughly be said that the results of the season of 1917 in the Willow Creek district were only about three-quarters of what they might have been had normal conditions prevailed.

PART OF ALASKA

× Denotes position of Willow Creek

The district was greatly handicapped, as all gold mining districts have been, by the scarcity of labor and the high price of materials and supplies. Also, though an isolated district, Willow Creek was affected by the general unrest of labor, two of the mines having been forced to close for nearly a month on account of strikes. The fact that the steamship companies carrying freight to Alaska could switch their vessels to the Atlantic and secure a profitable war business has allowed these companies to hold their freight-rates excessively high, even though they handle an immense business. The high price of cyanide has caused some of the operators to pond their tailings to await more favorable conditions.

At the Martin mine the 10-ft. Lane slow-speed mill has operated for four and one-half months this season, having been closed nearly a month on account of labor troubles. The

payroll has averaged about 20 men. Production will be \$85,000 for the season, which is considered satisfactory. The ore assays \$30 per ton, \$24 being caught on the plates and \$6 will be extracted by leaching when the price of cyanide is more favorable. During a large part of the summer the Lane mill was amalgamating \$1.10 gold per minute, and for a 10-day period the clean-up amounted to \$190 per hour. The bullion is high-grade, running about \$19.50 per ounce. Feed for horses is excessive and this in turn has increased the freight on supplies from the Government railroad to the mines. Mr. Martin has introduced an innovation in the form of a gasoline-driven air-compressor and jack-hammer drills. This machine was brought into the district by Fred Laubner to be used in a contract for tunnel-driving at the Gold Cord mine, but was later removed to the Martin mine, and the results have been most gratifying. It is to be hoped that the other operators will follow suit and install labor-saving machinery. In a trench behind the Martin mill a new vein has been uncovered; this is believed to be the continuation of the Gold Cord. The Independence mine was not operated beyond doing annual assessment work. A new vein has been uncovered back of the present mill, and it is believed that this also may be a continuation of the Gold Cord.

The Milo Kelly group, north of the Independence, between it and the Gold Cord, has shown up well. The adit of the Gold Cord was advanced during the year along an altered crushed zone in the grano-diorite for a distance of about 180 ft. This zone varies from 2 to 8½ ft. in width, and is said to give an average assay-value, for over 100 ft. long, of \$28 per ton. The gold, however, is not all free, being combined with pyrite. During the summer a tram was constructed from the mouth of the Gold Cord adit to the Independence mill, and the mill leased for a year. The owners of this property, Charles Horning, Charles Byron, and Frank Bartholf, and the Isaac brothers, expect to have tests made on the ore in order to determine the most advantageous flow-sheet and they expect to build a small mill next year. On a test-run of about 350 tons of ore from the adit, it was possible to recover only \$12 per ton on the plates.

The Rae-Wallace company, which is developing the Trickster and the Rosenthal groups of claims on the east side of Fishhook creek has opened up the orebody by an adit and cross-cuts for about 175 ft. The vein is 3 ft. thick. Another vein of high-grade ore has been uncovered on the property in numerous cuts and pits, and it promises well. Contrary to current reports, it is not believed that the orebody thus uncovered can be a continuation of the Mabel vein. It is planned to push development work during the winter and to build a mill next summer. This company is controlled by Coeur d'Alene men and has excellent prospects. It is so situated that a jig-back aerial tram of about 1600 ft. will serve to transport the ore from the mine to the mill. A pan-amalgamation test gave an extraction of over 90% of the gold. An artificial lake is to be made half-way up the mountain by building a dam across the mouth of a small glacial cirque; this will impound sufficient water to supply a small mill during the season, when the run-off is slight, and will give sufficient head to furnish power. There is a small copper-bearing vein on the property, and a little more trenching may show that this vein also is worthy of development. The ore so far developed has been opened only on the mountain-tops at an elevation of 1000 to 1500 ft. above the valley, and presents opportunities for quick development.

On Archangel creek, the Fern & Goodell property and the Gaikeme & Conroy properties were developed by assessment work, consisting largely of stripping the veins and driving short adits. These two properties have been taken under lease and option. Adjoining these properties to the south, the Talkeetna Mining Co., controlled by Mrs. D. M. Fulton, of Portland, Indiana, installed a 15-ton Denver quartz-mill, driven by

a Pelton wheel during the summer. Near the close of the season 50 tons of ore was milled, returning \$2000 worth of bullion. This company plans to install another tram and extend the power pipe-line farther up the mountain in order to catch a greater quantity of water before it has disappeared under the glacial wash. This extension will also give greater head on the Pelton wheel and the Denver quartz-mill simultaneously, which was heretofore impossible. It is also planned to block out and develop the orebody by lower adits during next summer.

George Anderson has had the Little Gem group under lease from Bob Hatcher. He has developed a small vein of high-grade ore and endeavored to use a hemp rope as an aerial tram to transport the ore from the mountain to the creek. Mr. Anderson drove 75 ft. of adit on a vein 14 in. wide and having a high-grade quartz stringer running through it from an inch to 2½ in. thick. He plans to float a company to work this property.

The Arch group property at the mouth of Sidney and Archangel creeks is being developed by open-cuts and pits. This group is owned by Colorado people. The Pilger group of claims, containing the northward extension of the Mabel vein, was represented during the year by trenching. It is planned to drive a cross-cut from near the bed of Archangel creek across the compact group. This should explore the Mabel vein from the lowest point at which it can be tapped by the shortest adit. The Mohawk Mining Co., on Sidney creek, bought two Gibson mills and two gas-engines, together with all necessary equipment. The Spokane capitalists who subscribed for a large block of the shares were disappointed later in the season because the ore failed to hold up in value on second examination. The Willow Creek Development Co., controlled by Anchorage business men, who have a lease and option on the claims of the Isaac brothers on Reed creek, has conducted discovery work in open-cuts and pits. About 500 lb. of ore was sacked to be shipped outside for test. On the results of this test depends the character of mill to be built next year. Major L. H. French has secured a lease and option on the Keystone group, owned by Messrs. Kelly, Laubner & Corlew, and on the Shough property on the Little Susitna river. He and his associates plan to do active development work during the coming year and hope to erect a mill.

The Mabel mine, owned by the Mabel Mining & Milling Co., of which William Bartholf is president and Fred Laubner is an important owner, made a five-months run during the summer. They employed an average of 16 men and milled 13 tons of \$40 to \$45 ore per day. Of the \$45, only about \$28 was plated in the mill, the rest having been ponded for further treatment at some future time. All of the mining thus far has been hand-work; consequently the cost has been high. During the year, the Denver quartz-mill and the penstock for the water-turbine were re-set.

On Craigie creek, the Gold Bullion mine operated for about five months, but was closed down for a short time by labor trouble. This property employed from 60 to 70 men during the year, of whom from 50 to 60 were in the mine. Power has been derived from water only; operations were hindered by shortage of water. This property is reported to have made a gross production of about \$150,000. The operating company is buying the property from the owners under a contract calling for payments extending over a term of years, one payment of \$160,000 out of a total of \$450,000 becoming due this year. It is rumored, however, that an extension of time will be granted.

Charles Bartholf and Dave Miller report a discovery of 2 ft. of vein-matter carrying a high-grade streak 2½ inches thick, on Craigie creek, about three miles below the Gold Bullion. They plan to erect a small prospector's mill next season, so that they may be able to thoroughly test the property and, at the same time, pay expenses.

## ALASKA

(Special Correspondence.)—Work at the Jualin Alaska mines has been suspended pending re-adjustments and preparations to start on a much larger scale. Work will be resumed before spring. It is intended to increase the present 10-stamp mill by an addition of a pebble-mill, bringing the capacity up to 150 tons per day. Work on the 7800-ft. adit, cross-cutting the entire property and draining the mine, will be resumed. The adit has already advanced 2000 ft. During the past 12 months the Jualin Alaska mines has recovered from its 10-stamp mill gold to the value of \$197,296. The mine is controlled by Belgium and French capital with its head office in Paris, France. Jualin, November 21.

(Special Correspondence.)—Labor conditions at Treadwell have greatly improved within the past few weeks and the scarcity of good men which prevailed during the summer has been almost relieved. At present 200 men are employed underground at the Ready Bullion mines, more than were working there previous to the cave-in of the other mines last April. Many of the old-time employees of the company have returned lately, some from the westward, where they went early in the year, and others from outside, where labor conditions are uncertain. The electric-steel furnace, recently completed for the Treadwell company, was requisitioned by the Government before shipment and sent to Watertown. A new furnace will be built and shipped as soon as possible. According to word just received, the Jualin mines will re-open before spring and will operate on larger scale. A Hardinge ball-mill is to be added to the present stamp-mill, bringing the capacity up to 150 tons per day. The drainage adit, which is already in 2000 ft., will probably be driven the full 5800 ft. necessary and will tap the orebody at a point 600 ft. below the present workings. Treadwell, November 26.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—Negotiation between the Cananea Consolidated Copper Co. and the authorities at Mexico City have culminated in terms under which the company is able to resume operation. All American employees have been recalled to positions formerly held at Cananea. The terms of the agreements have not yet been made public. Bisbee, December 1

### MARICOPA COUNTY

(Special Correspondence.)—The Hatton property six miles north-west of Aguila is shipping one carload of manganese ore per week. Manganese properties to the south of Aguila are also shipping. Phoenix, December 1.

### MOHAVE COUNTY

(Special Correspondence.)—The old 63 mine in the Stockton Hills district has been purchased by G. E. Pierce of Kingman. A 400-ft. adit has been driven to cut a 30-in. vein of high-grade silver ore, running as high as 3000 oz. per ton. Several miles of road has been graded, and an air-compressor, gasoline engine, and other machinery erected.—The Walk Over mine, adjoining the Copper Giant, nine miles from Hack-

berry, is pushing development. The mine is equipped with a 25-hp. Fairbanks-Morse gasoline hoist, an 8 by 10 Ingersoll-Rand compressor, and jack-hammer drills.

Kingman, December 10.

(Special Correspondence.)—The main ore-shoot in the north drift of the 300-ft. level of the New Tennessee has been broken into. The ore is of good grade.—Recent developments on the 400-ft. level of the Gray Eagle shaft of the Tom Reed has

PART OF ARIZONA

opened up ore for 75 ft. which it is claimed averages \$20 per ton. It is estimated that there is 500 ft. of backs in this orebody.

Kingman, November 30.

### PIMA COUNTY

(Special Correspondence.)—The Indiana Arizona silver-copper mine at Silverbell has been bonded to A. Knox, of Los Angeles, for \$200,000.

Tucson, November 30.

### PINAL COUNTY

(Special Correspondence.)—The first of four diamond-drill holes to test the orebody of the Magma Chief Copper Co. has been started. All drilling is under contract, the depth of the holes average 550 ft.—The last 300 ft. of the Magma Chief adit has been giving gold and silver in heavily iron-stained porphyry.

Florence, November 30.

## YAVAPAI COUNTY

(Special Correspondence.)—A considerable flow of water has been cut in the Dundee Arizona shaft, which is down 500 ft., causing some delay. Twelve carloads of carbonate ore averaging 5% copper is being shipped per month.

Prescott, December 1.

The Loecy Pabst Gold Mining Co. has been organized to take over the Union mine, the property of the estate of the late John S. Jones. A 1200-ft. adit has been driven to facilitate the tramming of ore from the mine to the 10-stamp mill. In driving this two veins were cut, 8 ft. and 6 ft. wide, respectively. A chamber has been cut and an inclined shaft is being sunk on these veins, which are only 6 ft. apart. The average value of the gold and silver content is said to be \$15 to \$18 per ton. The mine is equipped with a 20-hp. gasoline hoist, a Sullivan air-compressor, four jack-hammer drills, a 10-stamp mill, and a Wilfley table.—Work is being continued at the Silver Belt mine and some high-grade silver-lead ore has been uncovered. The shaft is down 300 ft., and 400 ft. of levels has been driven.—Preliminary prospecting drifts and cross-cuts from the 140-ft. shaft on the American Eagle group of the Arizona Copper & Mining Co. have cut some good-grade chalcopryite ore. The company proposes to do some extensive developing on a heavily-mineralized belt of schist ranging from 30 to 300 ft. wide.

## YUMA COUNTY

(Special Correspondence.)—A number of producing mines and many prospects are being operated on the Harqua Hala mountains, 65 miles south-east of Parker. The Swansea and the Planet mines have both been producing steadily for over a year. The Empire-Arizona and the Billy March have shipped considerable high-grade ore.—The Mammoth Gold & Copper Co. is sinking a three-compartment shaft. Over 5000 ft. of development work has been done and ore running 7% copper and \$7 in gold has been found.—At the Empire-Arizona, which has been worked intermittently for several decades and on which some 10,000 ft. of developing has been done, a 350-ft. level has been driven on a vein of oxidized copper ore, carrying \$2 to \$3 in gold.

Parker, December 1.

## CALIFORNIA

## INYO COUNTY

A large body of zinc ore has been uncovered by Utah miners nine miles from Darwin. Near the surface the orebody is said to have a width of 500 ft. Shipments are being made at the rate of 45 tons per day.—The Standard Tungsten Co. has increased the capacity of its plant and is handling a large tonnage.

## SAN BERNARDINO COUNTY

(Special Correspondence.)—The Tom Reed Gold Mines Co. is sinking a vertical shaft in the hanging wall of a body of quartz on the Clipper mountains. The shaft is down 300 ft. and when a depth of 500 ft. is reached a station will be cut and the vein thoroughly explored.—The Tom Reed Gold Mines Co. of Arizona is developing a large body of quartz that is 50 ft. wide and in places stands up 100 ft. above the surrounding rock. The shaft, which is being sunk on the hanging wall, is down 300 ft., and will be continued another 200 ft., when a station will be cut and levels driven.—The Clipper Gold Mining Co. of Los Angeles is developing a claim adjoining the Tom Reed.—The Merger Mines Co., T. B. Bassett of New York, president, has taken over the Black Hawk mine, 36 miles east of Victorville. This property was located in 1887 and a 10-stamp mill erected. There is a 30-ft. vein which is said to carry \$4 in gold.

San Bernardino, December 8.

(Special Correspondence.)—The Mohave United Mining &

Milling Co. has uncovered a considerable body of ore, the extent of which has not yet been determined, running 20% copper and \$18 in gold. The mine is situated at Crucero.

Crucero, December 8.

## SIERRA COUNTY

The new 10-stamp mill at the Ireland mine, near Alleghany is in operation and running satisfactorily. Development at the mine is being pushed.

## TUOLUMNE COUNTY

(Special Correspondence.)—Activity in chrome mining in the western part of the county is steadily increasing. It is estimated that shipments now amount to 1000 tons per month. This represents the output of eight properties that have been worked for only a few months. The operators who are making shipments regularly are Booker, Powell & Porter, Richards Bros., Pereira Bros., Eglin & Williams, Sell & Terry, Charles Gillis, Robert McCormick, and Charles Quigg. The properties are all situated in the serpentine belt west of the Mother Lode, and are traversed by the Sierra railroad. Several other prospects are being opened, among the most promising being those of John Bullock and Aaron Morgan.—With about 175 men on the payroll, the Shawmut mine is pushing development work, making changes in its surface plant and adding new machinery, including an electric hoist on the third level. The number of stamps in the mill is being reduced to 60, but a Hardinge ball-mill and a flotation plant are being put in. An adit 2800 ft. long connects the mill with the hoist, thus making possible the abandonment of the upper part of the shaft.—At the Dutch mine work is still confined chiefly to sinking and making underground improvements.—An electric-transmission line has been built to the Star King mine and operations have been resumed, after a suspension of several months.—Another good orebody is being opened at the Chaparral mine. The first Ellis ball-mill made was used at this mine.

Sonora, December 4.

## COLORADO

## BOULDER COUNTY

(Special Correspondence.)—George Chesebra and Robert Kermick are building a fluorspar mill. There is an abundance of medium-grade fluorspar in this county, especially in the Jamestown section, but it requires concentrating before it can be shipped at a profit. F. B. Cahill is the foreman. The U. S. Geological Survey has made a thorough examination of the county with a view to estimating available sources of the mineral. The St. Elmo Tungsten Mining Co. has been incorporated with J. Taylor Smith, president; George Pomeroy, secretary and treasurer; and U. A. Ashley, foreman. It has acquired the St. Elmo and Mountain Queen claims, one mile north-east of Nederland. Operations on the Mountain Queen have already been started. The Quay mine, near Nederland, leased by Snowden & Co. from the Tungsten company, has had a successful season.—The Wolf-Tongue mill at Nederland, C. E. Dewitt superintendent, is being worked at full capacity. The Vasca mine is running two mills, one at Stevens camp and one at Boulder, and is doing considerable development work at Stevens camp.

The output of the mines at Caribou this winter is far above that of any previous year and is evidence of the revival of silver mining. The ores average from 100 to 400 oz. per ton. The Potosi, under lease to Davis & Linstrom, is one of the most active in the district. A two-car shipment was sent out last week.—The Tungsten Metals Co., under the management of W. W. Charles and George Teal, has acquired the old Kekionga mine at Magnolia.—The Victoria mine, situated at Summer-ville, is producing high-grade ore, running from 55 to 300 oz. in silver. Frank J. Pickford is foreman; a large force of men is employed.

The Yellow Pine group, owned by Ralph Cotton, has had a successful season; the Michener being the heaviest producer.

The ore runs 10% copper, 18% lead, and 200 oz. in silver. Regular shipments are being made.—Charles Walstrom, who has a bond and lease on the old Fairfax property at Salina, has been adding new machinery, preparatory to more extensive work. The Logan mine, at Chrisman, is being worked by lessees and is making a good production.—Miner Smith, George Sale, Robert Smith, John Walgren, William Thompson, and James Francis are all shipping from their respective leases.—Around Eldora, work at the Huron and the Consolidated Leasing is going ahead and will be continued all winter.

Eldora, December 3.

#### LAKE COUNTY

(Special Correspondence.)—At a special meeting of the stockholders held at Denver, November 26 and 27, the Yak Mining, Milling & Tunnel Co., sold an undivided half interest in its property at Leadville to the American Smelting & Refining Co. With the sale the Yak company turned over to the A. S. & R. Co. the management of the property. The consideration for which the transfer was made has not been stated. The management of the Yak by the smelting company is expected to be a decided benefit not only to the property itself but also to the entire district. For almost a year operations at the Yak have been on a much smaller scale than has been customary. The big orebodies of the Cord and White Cap, which formed the greatest source of production, were exhausted several months ago, and, owing to continued trouble with the draining equipment in the Cord, White Cap, and Diamond, development has proceeded slowly and with difficulty. A number of new ore-shoots are reported to have been uncovered, but they are low grade and prospecting has not yet reached a stage where the value of these discoveries can be determined. The Yak has been one of the biggest dividend payers in the district, maintaining an unbroken record until this year. Expensive pumping equipment and driving development-drifts has consumed the return from shipments made during the past six months, and it is believed that this is the reason for turning the property over to the smelting company.

Leadville, December 3.

#### TELLER COUNTY

(Special Correspondence.)—The output of the Cripple Creek gold mining district for the month of November was 95,358 tons, with an average value of \$10.95 per ton and gross bullion value of \$1,044,697. The feature of the production was the heavy output of low-grade ores, namely, 57,600 tons, assaying below \$2.20 per ton.—The dividends during the same period totalled \$167,000, and were as follows: Cresson Consolidated G. M. & M. Co., 10c., \$122,000; Golden Cycle M. & R. Co., 3c., \$45,000.—The treatment at the several mills was:

Plant and location	Tons treated	Average value	Gross bullion value
Golden Cycle M. & R. Co., Colorado Springs .....	25,500	\$23.00	\$586,500
Portland G. M. Co., Colorado Springs .....	9,758	20.50	200,039
Smelters, Denver and Pueblo .....	2,500	55.00	137,500
Portland G. M. Co., Independence Mill .....	39,400	2.06	81,164
Portland G. M. Co., Victor Mill....	18,200	2.17	39,494
Total .....	95,358	\$10.95	\$1,044,697

The Trail, Big Banta, Old Ironsides, and Lost Fraction lode mining claims, U. S. Mineral Survey No. 7812, containing 25,338 acres on Bull hill and Battle mountain, originally owned by the Regua Gold & Silver Mining Co., now expired by limitation, were sold at public auction on November 30, and were purchased by H. McGarry, of Colorado Springs, representing the United Gold Mines Co., owner of 70% of the capital stock of the defunct company, for \$71,000. W. H. Hayes of

Pasadena, and W. H. Wolfe of Parkersburg, submitted bids at the sale. Leases on the Trail and Big Banta lodes will continue, as the sale was made subject to existing written leases.—The Geraldine Mining Co., recently organized by Lamar investors, has secured sub-leases on blocks of the Victor mine, and a portion of the estate of the Anona Mining Co. adjacent, on the eastern slope of Bull Cliffs, and during the past week has laid track in the old Victor adit, from which the territory will be exploited. The Victor mine is owned by the Smith-Moffat Mines Co.—The Acacia Gold Mining Co. has opened a promising ore-shoot at the bottom or 1400-ft. level of the South Burns mine on Bull hill, beyond the junction of the Shurtloff-Eagles vein. The company and its lessees shipped nine cars of 300 tons of \$30 grade during November.—The directors of the Isabella Mines Co. have appointed Frank Gunn of Cripple Creek superintendent and managing director to succeed Clarke G. Mitchell, who has voluntarily enlisted in the U. S. Aviation Signal Corps.

Cripple Creek, December 6.

#### IDAHO

##### SHOSHONE COUNTY

The Spokane Metals Recovery Co. has been capitalized at \$100,000 and recorded at Wallace, Idaho, with principal place of business at Mullan. The company has a lease on a flat at Nine Mile, where 50,000 tons of tailing from the Rex mine has accumulated, and has also arranged to secure tailing from the Interstate Callahan, Success, and other mills. Samples show values running over \$6 per ton. The company expects to make a profit of \$1.50 per ton.

#### MAINE

##### HANCOCK COUNTY

The soundness of C. Vey Holman's judgment in re-opening the old Douglas mine in the summer of 1915 has been fully demonstrated. The American Smelting & Refining Co. took the property over and has 150 men on its payroll at the mine. It is meeting with satisfactory results. Mr. Holman, who was at one time State geologist, has long advocated the re-opening of some of the old mines of the State.

#### MONTANA

##### SILVER BOW COUNTY

(Special Correspondence.)—Benjamin B. Thayer, vice-president of the Anaconda Copper Mining Co., left Butte, after completing an inspection of all the properties of the company at Butte, Great Falls, Anaconda, and other parts of the State. From Butte he will go to Tooele, Utah, where he will inspect the International Mining & Smelting property. Mr. Thayer said the output of the mines was gradually getting back to normal, at the present time it equalled 88% of the production previous to last June, and that by the end of the year it would have recovered completely. Mr. Thayer found both mines and smelters in excellent condition.—The Anaconda Copper Mining Co. is now employing 9280 men and hoisting 13,772 tons of ore per day, 685 tons of which is zinc ore. In the last two days 169 miners have been given employment.—The Montana Institute of Mining Engineers held a banquet at the Silver Bow Club, November 16. Some interesting papers were read and discussed. Benjamin B. Thayer gave an account of what is being done by the Naval Board, of which he is a member. He was given a most cordial reception by his many old friends. C. W. Goodale read notes on the St. Louis meeting; Reno H. Sales discussed the manganese situation; E. M. Norris gave a splendid paper on the fire-proofing of the Butte shafts; C. L. Berrien explained the process of the hydraulic filling for extinguishing fires at the Leonard mines.—A gradual improvement is being shown in the labor situation in the Butte district. The Tramway mines, one of the largest producers in the district, resumed work on November 19. It had been idle

since October 3, on account of repair-work. In the last two days 169 miners have been given employment.

Butte, December 3.

## NEVADA

### ELKO COUNTY

(Special Correspondence.)—At the Liberty Gold Mines Co., operating at Liberty, 64 miles north of Elko, a combination gravity-concentration and flotation plant will be erected early in 1918. The plant will have a capacity of 150 tons per day. On the 130-ft. level, the deepest point in the mine, the vein shows a width of 42 ft. with portions assaying \$25 to \$30 per ton in gold and copper. F. H. Bird, former superintendent of the Seven Troughs Coalition, is manager.—A promising deposit of cinnabar is being developed 90 miles north-west of Elko by the Ivanhoe Springs Co. This is the first discovery of an important quicksilver deposit in this part of Nevada. Development is confined largely to surface working; two retorts are operating on selected ore. W. C. Davis is manager.—The old silver camp of Cornucopia is showing signs of a revival. Some promising strikes have been reported recently, and on the Peacock property a high-grade vein has been opened near the surface. It is a cross-vein and carries horn-silver and black sulphide. The camp is near Tuscarora.—Frank Middleton and Bruce Bros. are developing extensive deposits of shale in Burner basin, six miles east of Elko. Tests indicate the shale contains a high proportion of oil; it is planned to extract the gasoline and other products by the Crane method. Sinking of a 100-ft. shaft has begun.—L. R. Thatcher and associates have filed on several hundred acres of shale land near Pallisade, and started development. The shale is reported to test 80 to 90 gal. of petroleum per ton. Mr. Thatcher states a 100-ton plant will be erected, and also a custom smelter to treat silver-gold ores in this field. The smelter is to be operated by gas obtained from the shale beds.

Elko, December 9.

### MINERAL COUNTY

(Special Correspondence.)—The United States Refining, Smelting & Mining Co. has arranged to treat a heavy tonnage of gold ore from the R. B. T. mine and silver-copper ore from the Luning-Idaho group. The gold ore, being highly silicious, will be shipped to the Mammoth smelter, near Kennett, and the silver-copper product to Utah plants. The mines are situated near Luning. The grade of the R. B. T. shipments will range from \$20 to \$40 per ton.—S. M. Summerfield of Mina, representing California capital, has purchased the Garnet group of tungsten claims, 13 miles east of Mina. The terms of purchase specify that the construction of a concentrating plant must be commenced within 90 days. It is reported the purchase involved \$60,000, and that the Atkins-Kroll Co. is interested.—The group of tungsten properties at Sodaville have been re-opened by A. C. Beck and associates, and the mill is being repaired. Caterpillar tractors and self-dumping trailers have been ordered; mine development is progressing steadily.—The Montgomery Mountain Quicksilver Co. has arranged for the erection of a battery of D-shaped retorts. A large tonnage of profitable ore has been opened. The mine is near the Nevada-California line, five miles east of Montgomery Mountain station, and 40 miles south of Mina. F. C. Beedle is manager.—The furnace capacity of the plant of the Mina Quicksilver Co. is being increased from 14 to 23 retorts, which will enable a production of 10 flasks of quicksilver per day. On the 155-ft. level the vein is 11 ft. wide, and averages 7% mercury. The company is controlled by Manson & Humphrey of Reno.—An important strike is reported from the Aurora Consolidated, at Aurora. In the main adit an orebody of considerable size has been uncovered, and is reported to assay \$25 to \$30 per ton. The management is centring work at this point and sending a heavy tonnage to the 500-ton mill. Development is proceeding to determine extent of the lode. The

Goldfield Consolidated holds 85% of the stock of the Aurora company.

Mina, December 2.

### NYE COUNTY

Drift No. 19 at the MacNamara is progressing well. Stopes No. 1 and 2 on this level show an 8-ft. and 5½-ft. face, respectively, of good ore. Stoping on the Ohio vein on the 500-ft. level continues in good ore. The output last week was 507 tons.—The Jim Butler Tonopah Mining Co. during October milled 3500 tons of ore, resulting in a net profit of \$28,242. At the Wandering Boy shaft raise No. 369 on the 300-ft. level continues on a 5-ft. face of medium-grade ore. The production the past week was 750 tons.

The Cash Boy commenced stoping on the 1700-ft. level, and is shipping the ore to the smelter at Keswick, California. The shipments are being sampled at Hazen, Nevada, by the Western Ore Purchasing Co. The drifts in the hanging wall and the foot-wall continue in excellent ore, and the raise in the hanging wall, which is being driven for a connection, shows a face of good ore.—The Rescue-Eula produced 66 tons of ore, the Cash Boy 50 tons, and miscellaneous 39 tons, making the week's production at Tonopah 10,125 tons with a gross value of \$177,187.—The Tonopah Divide Mining Co. at Gold Mountain, which is situated six miles south of Tonopah on the Goldfield road, has opened a vein of silver ore. The property has previously shown only gold-bearing veins, so the present discovery was entirely unexpected. The vein has not been thoroughly prospected, but specimens from it are exceptionally rich. A large ore-bin is being erected. All the surrounding claims have been purchased by H. C. Brougher, who is president of the company.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—The Socorro Mining & Milling Co. is making rapid progress in the re-building of its mill and mine plant. The local saw-mill has been secured, the company's own force being sent into the woods. All logs are in and sawed timber has been arriving in camp for the 10 days. All lumber needed for the re-building of the plant will have been delivered by the end of next week. Permanent buildings around the plant are starting; a 70-ft. steel head-frame will replace former structure and the plant will be more efficient throughout.—The Mogollon Mines Co. is running at capacity. All tonnage coming below the adit-level is now being handled through the new two-compartment shaft, which is equipped with two counter-balancing self-dumping skips.

The Oaks Co. is maintaining daily shipments from the Maud S. and Deep Down mines. The Central shaft is being timbered to water-level and sinking will soon be in progress. This company is also actively developing the Clifton, Eberle, and Pacific mines, and is shipping ore from all of them.

Mogollon, December 4.

## TEXAS

### TRAVIS COUNTY

(Special Correspondence.)—Development of the quicksilver deposits, the sulphur beds, and the silver and copper mines of the upper border region of Texas has been greatly stimulated by the existing high prices of these minerals, according to the statement of William B. Phillips, formerly director of the Bureau of Economic Geology and Technology of the University of Texas. Mr. Phillips has just returned from a trip through that region. The activities in the Terlingua quicksilver district are unusually brisk. Notwithstanding the fact that the mines are situated 90 to 100 miles from the nearest railroad point, the high price for which the metal is selling has caused the re-opening of old mines and of much prospecting work, which, it is to be hoped, will provide fruitful results.

The quicksilver mines in Texas are in the southern part of Brewster county, 400 miles west of San Antonio. The existence of cinnabar in that part of Texas has been known since 1894, but it was not until 1897-'98 that any efforts were made to utilize the discovery. Since then, however, the total production has been about 75,000 flasks.

Austin, December 7.

## WASHINGTON

### STEVENS COUNTY

An average of 180 tons of calcined magnesite is being maintained by the Northwest Magnesite Co., operating near Chewelah. A big reserve is being created while shipments go forward steadily. Meantime the big calcining plant is rapidly nearing completion. The third metal kiln has been put in operation and the six-mile tramway is virtually completed. The plant and tramway represent an investment of \$250,000. Twenty carloads of calcined material has been shipped by the Valley Magnesite Co., operating in the same locality. As the cars contained about 40 tons, and each ton has an average value of \$32.50, with an operating and hauling charge of \$10, a net profit of \$18,000 is shown on the shipment.

The United Copper Co. has passed its December dividend. Reasons assigned are that the smelter at Trail, B. C., is closed on account of a strike and it is also thought advisable to build up a little more surplus on account of the excess-profits war-tax. Shipments to the smelter at Tacoma are continued and it is expected that dividend payments will be resumed in January. The company has been disbursing \$10,000 per month this year.

## CANADA

### BRITISH COLUMBIA

Andrew G. Larson, operating the Lucky Jim mines in the Kootenay district, B. C., in the capacity of receiver, has made an enviable record during the past two years. In that time he has satisfied a mortgage of \$55,000 and the claims of unsecured creditors, aggregating \$15,000, and established a reserve of \$8000. In addition the mine has ore worth more than \$8000 in transit and ore worth \$5000 on hand. The total of these figures is \$91,000. Production has been maintained at the rate of 50 tons per day.

### ONTARIO

The following table, compiled by the Bureau of Mines, gives the mineral production of the Province of Ontario for the first nine months of 1917. The production during the same period of 1916 is given for comparison.

	Quantity		Value	
	1916	1917	1916	1917
Gold, oz. ....	363,955	343,490	\$7,513,734	\$6,754,535
Silver, oz. ....	16,203,091	15,236,002	9,750,040	12,001,875
Cobalt (metallic), lb. ....	172,055	295,865	146,467	438,732
Nickel (metallic), lb. ....	17,435	166,921	7,618	67,499
Nickel (oxide), lb. ....	54,152	10,831	6,381	3,025
Cobalt (oxide), lb. ....	378,732	276,769	231,947	323,162
Other cobalt and nickel compounds, lb. ....	57,026	276,217	22,890	30,025
Molybdenite, lb. ....	15,845	65,827	15,845	83,550
Copper ore, tons. ....	1,715	2,658	21,685	33,419
Nickel in matte, tons. ....	31,046	31,064	15,523,000	15,532,000
Copper in matte, tons. ....	16,989	15,928	6,285,930	6,371,200
Iron ore (exported), tons. ....		98,757		412,401
Pig-iron from domestic ore, tons. ....		48,820		936,118
Lead, tons. ....		540		136,948

1916 figures are not available for the last three items.

## NICARAGUA

A new gold-silver-lead deposit has been discovered 12 miles south of Matagalpa, between the Leonesa and the Mina Verde gold mines. N. DeLaney, Gus Fraumberger, and W. H. DeSavigny are the principals, and claim to have 6 ft. of galena, running high in gold, silver, and lead. An engineer has been engaged who will leave for Nicaragua to investigate.

# PERSONAL

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

HUGH ROSE is in London.

FRANK W. OLDFIELD is at Mexico City.

R. S. ARCHIBALD is in the Black Hills region.

J. M. CALLOW was in San Francisco this week.

CHARLES BUTTERS is due here from Washington.

JOHN B. WISE has returned to Chuquicamata, Chile.

HARRY D. GRIFFITHS has left London to go to Burma.

J. G. SHANNONHOUSE has returned from Mazatlan, Mexico.

ANTONY F. LUCAS has returned to Washington from Texas.

JOHN A. RICE has returned from a geologic inspection at Cananea, Mexico.

PHILIP BRADLEY, superintendent of the Alaska Juneau mine, visited San Francisco this week.

WALTER H. ALDRIDGE passed through San Francisco on his return from Arizona to New York.

W. F. COLLINS has returned from China and is helping to organize Chinese labor in France.

E. V. DAVELEE, superintendent of the mills of the Alaska Gold Mining Co., is in San Francisco.

J. B. MOORE has resigned as mine superintendent for the Tigre Mining Co. and is now at San Antonio, Texas.

HARRY J. SHEAFE has completed his military training at Fort Leavenworth and is now at Chicago awaiting orders.

FREDERIC R. WEEKES has moved his office from 71 to 42 Broadway, New York. He is returning from California to New York.

P. K. LUCKE has resigned as consulting engineer to Cia. Minera de Peñoles in Mexico to resume private practice at San Antonio, Texas.

JOHN J. CROSTON, lieutenant, has been transferred from the 23rd Engineers to the 27th Engineers, the Miners Regiment, at Camp Meade, Florida.

E. A. HOLBROOK, formerly professor in the mining department of the University of Illinois, has been appointed Supervising Mining Engineer and Metallurgist for the U. S. Bureau of Mines and will serve as superintendent of the station at Urbana, Illinois. W. B. PLANK has been appointed mining engineer in the Mine Safety Section, with headquarters at the same station.

## Obituary

ALFRED WINTER EVANS, D.S.O., D.C.M., Lieutenant-Colonel, New Zealand Rifle Brigade, was killed in action on October 12, 1917. Evans was a mining engineer, Columbia '06. After graduation he worked in Utah and Arizona for a year or more before going to the Rand, South Africa, where he followed mining till 1911 when he went to New Zealand as general manager for the Consolidated Gold Fields of New Zealand Ltd., which position he was filling when war was declared. He had seen service in the South African war, was twice recommended for the Victoria Cross by the late Field Marshal Sir George White, and was awarded the D.C.M. with a commission. He was mentioned in dispatches after the Somme for gallantry in the field, and awarded the D.S.O. after the battle of Messines. Always a credit to his profession he possessed in a rare measure those traits of character that endeared him to his friends and commanded the respect even of those who differed from him. A friend testifies that he worked with Evans through many trying circumstances, especially in connection with mine-fires and the New Zealand miners strike of 1912, and never saw him weaken when tried, or knew him to send a man where he would not go himself.

# THE METAL MARKET

## METAL PRICES

San Francisco, December 11

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	16.00
Antimony (wholesale), cents per pound.....	15.25
Electrolytic copper, cents per pound.....	23.50
Pig-lead, cents per pound.....	6.50—7.50
Platinum, soft and hard metal, respectively, per ounce.....	\$105—113
Quicksilver, per flask of 75 lb.....	115
Spelter, cents per pound.....	11.50
Zinc-dust, cents per pound.....	20

## ORE PRICES

San Francisco, December 11

Antimony, 45% metal, per unit.....	\$1.00
Chrome, 34 to 40%, free SiO <sub>2</sub> , limit 8%, i.o.b. California, per unit, according to grade.....	\$0.80—0.70
Chrome, 40% and over.....	\$0.70—0.85
Magnetite, crude, per ton.....	\$8.00—10.00
The magnetite market remains practically the same; considerable calcined and raw magnetite has been offered, but no business to amount to anything has been reported.	
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.	
Tungsten, 60% WO <sub>3</sub> , per unit.....	23.00
Molybdenite, per unit MoS <sub>2</sub> .....	\$40.00—45.00

## EASTERN METAL MARKET

(By wire from New York)

December 11.—Copper is unchanged at 23.50c. all week. Lead is dull and firm at 6.50c. all week. Zinc is inactive and lower at 8 to 7.87c. Platinum is unchanged at \$105 for soft metal and \$113 for hard.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Samuel Montagu & Co., of London, state: The net imports of silver into India during July 1917 were heavy. The total was 8,867,052 oz.; allowing for exports amounting to 2,460,227 oz., the net imports were 6,406,825 oz. The net imports of silver during April, May, June, and July amounted to the substantial weight of 33,702,629 oz. valued at about \$5,314,000. Of this total the Indian government was responsible for no less than 30,552,487 oz. The stock of silver at Shanghai on November 3 consisted of about 25,700,000 oz. of sycee-silver and \$14,900,000, as compared with 25,200,000 oz. in sycee and \$15,200,000 on October 27.

Production reports for November are not as favorable as was at first expected. Anaconda's November production of 21,666,332 lb. of copper showed a decrease of 633,668 lb. from October. This was due to closing down of the Leonard mine for a week, occasioned by escaping gas from a fire on the 1300-ft. level. On December 1, 12,211 tons of copper ore was hoisted. Anaconda is now operating at 94% capacity and officials say, barring unforeseen setbacks, December production should reach between 25,000,000 and 26,000,000 lb. of copper. The Great Falls refinery is operating at 65% capacity. A preliminary statement of the Porphyries output for November shows a falling off of about 2,000,000 lb. as compared with October. Utah's output last month was 16,300,000 lb., whereas in October it was 18,100,000 lb. Miami, on the other hand, shows a satisfactory increase, its November production being given as 3,361,426 lb. as compared with 2,673,775 lb. in October.

Statistics of the production of lead and zinc pigments in the United States, compiled by the U. S. Geological Survey, show that the marketed output of these pigments of domestic manufacture in 1916 reached a value of \$60,370,319, as compared with a value of \$43,336,939 reported for 1915, an increase of more than 39%.

The higher price of pig-lead in 1916 evidently curtailed the production of pigments made from it, and at the same time, in conjunction with other war conditions, largely increased the value. The decrease in quantity amounted to 11,901 tons, or about 6%; the value increased \$6,447,583, or about 26%. It is not permissible to give separately the figures for sublimed lead, zinc oxide, and leaded zinc oxide, as to do so would disclose individual output. The combined production of these pigments in 1916 amounted to 135,606 short tons, valued at \$23,515,520, as against 141,393 short tons, valued at \$14,982,461, in 1915, a decrease of 4% in quantity and an increase of 57% in value. Manifestly war conditions were operative in this branch of the pigment industry also. As stated in the Survey's report on barium products, 51,291 short tons of lithopone of domestic manufacture, valued at \$5,798,927, was marketed in the United States in 1916, as compared with 46,494 short tons, valued at \$3,760,472, in 1915.

## QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date	Nov. 27.....	110.00
Nov. 13.....	100.00	115.00

June ....	40.26	42.07	61.93

## ORES

Tungsten: The market has come to a standstill because of a railroad embargo on shipments leaving New York, causing buyers to abstain from the market. The embargo on imports has put a damper on further business because of expected delays in getting licenses. Also some tungsten-ore shippers in South America are of German nationality. Prices are largely nominal at \$23 to \$25 per unit for wolframite, and \$26 to \$27 for scheelite. One sale of wolframite, high grade, at \$25 is noted. Ferro-tungsten is unchanged at \$2.25 per lb. of contained tungsten.

Molybdenum and antimony: There is but little change in these ores, with the market quiet. Molybdenite is quoted at \$2.25 per lb. of MoS<sub>3</sub>.

# Eastern Metal Market

New York, December 5.

Practically all the metal markets have come to a dead standstill. There is very little business outside of that occasioned by Government activity and by war-requirements.

Copper conditions are unchanged. It is a Government-controlled product.

Tin continues scarce and nominal at high prices. There is no activity.

Lead is in poor demand, but prices are firm at unchanged levels.

Zinc is still lifeless, and nominal at the same quotations as last week.

Antimony is more active and higher.

Aluminum continues dull.

In the steel-trade steel producers have been called upon for cost-sheets in the last week by the Federal Trade Commission. There is also expected renewed agitation of Government control and of price reductions from the same source, synonymous with the calling of the Pomerene bill in Congress. The outlook, in the opinion of 'The Iron Age,' is by no means encouraging in the face of production and distribution troubles. Steel and iron exports have been much reduced despite considerable demand from foreign sources. The Government is still in the market for large orders for plates and forging-steel for shells. There is little said, however, about shell-steel for the Allies. The November pig-iron output was unexpectedly larger than in October, or 106,859 tons per day as against 106,550 tons per day in the latter month.

## COPPER

There is very little to say about the copper market in addition to what was said last week. There is no general market. The situation is absolutely under Government control. Distribution is evidently going on in an orderly and satisfactory manner. Very little is heard in the way of complaint. As stated last week, metal is sold only at the Government price of 23.50c. per lb. for delivery in the first quarter and also for prompt delivery to consumers having Government contracts. The settling of the jobbers' position has relieved the situation in this field, and orders of small lots are going at 5% above the Government price, and probably at a fair profit above cost in some cases. The November output of refined copper has been higher than that for October, but it is believed to be considerably less than the maximum in 1916. The statement is made that, after the needs of our own Government and those of the Allies are met, the supply for domestic consumption will be small, with the prospect that this state of affairs will continue for a number of months. Copper exports in 1916 were 784,000,000 lb., according to B. S. Butler of the U. S. Geological Survey. This compares with a 10-year average of 735,000,000 lb., and with a record exportation of 926,000,000 lb. in 1913. The 1916 domestic consumption is put at 1,430,000,000 lb. at an average price per pound of 24.6c., which compares with a 10-year average of 773,000,000 lb. at 16.3c. per lb. Our production of primary copper in 1916 is reported as 2,259,000,000 lb., of which 1,928,000,000 lb. was smelted from domestic ores. The 10-year average up to 1917 was 1,502,750,000 lb. produced, of which 1,201,400,000 lb. came from domestic ores.

## TIN

The tin market has been very dull and quite neglected during the last week. Spot Straits continues unobtainable at the

highest price ever recorded. It is therefore nominal at 80 to 81c., New York. Banca and Chinese tin are also scarce and are quoted nominal, at high prices. No. 1 Chinese was nominal yesterday at 75c., New York. These grades have been in better demand recently because of the shortage of Straits tin and therefore stocks have been drawn upon for sale and consumption until the supplies are less. The only new item of interest in the week is that the tin in warehouses, which was announced last week as commandeered by the Government, has been all released—except such as was appropriated for direct use by the Government. It is again in the possession of those who bought it, subject to distribution by the American Iron and Steel Institute, and under Government control. The market is now a completely regulated one, the same as copper. In general, demand is light, with little or no business reported. Buyers show no interest in any grade for any position. There is no prospect of immediate relief to the spot-situation. The entire market has come to a halt. Arrivals to December 4, inclusive, have been 325 tons, with the quantity afloat unreported. Spot Straits in the London market yesterday sold at £294 per ton, an advance of £10 per ton over last week.

## LEAD

Conditions are entirely unchanged from those outlined in last week's letter. The market is dull, and there has been little or no business. Prices are firmly held at not less than 6.50c., New York, or 6.37½c., St. Louis, in the outside market. The American Smelting & Refining Co.'s quotation is unchanged at 6.25c., New York. There is no pressure to sell, neither is there any anxiety to buy, and the situation is therefore a stand-off. Lead in transit has sold during the week in carload lots and less at 6.75 cents.

## ZINC

The market is still in the doldrums without interest or life. The trade seems to be waiting for the results of the new Zinc Committee's deliberation with the Government as to price-fixing and other matters, concerning which nothing yet has been made public. The market is bare of demand, and sales are few. Quotations, mainly nominal, are unchanged from last week, with prime Western for early delivery quoted at 7.75c., St. Louis, or 8c., per lb., New York. These prices are being shaded slightly in some cases, but not so as to greatly affect sentiment on the market. Spelter-exports in September, just announced, were large, amounting to 25,333 gross tons, of which 17,322 tons was made from foreign ores. This fact is regarded as explaining why the accumulation of stocks at smelters in the third quarter was not large. Zinc ore in the Joplin district has declined to \$50 to \$70 per ton as compared with \$57.50 to \$72.50 last week.

## ANTIMONY

The effect of the President's proclamation of an embargo on imports has decidedly strengthened this market, and, as a result, as high as 16c. per lb., New York, duty paid, was bid yesterday for Chinese and Japanese grades. Sales are reported at 15.25c. per lb. It is expected that available supplies, especially for spot and early delivery, will be curtailed, and there has been a scramble to obtain those now available. It is too early to forecast the ultimate effect of the new conditions on the market.

## ALUMINUM

The market is stagnant and unchanged at 36 to 38c. per lb., New York, for No. 1 virgin metal, 98 to 99% pure.

# INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

## PNEUMATIC ROTARY DUMP

The Wood Equipment Co. of Chicago, has been organized for handling the sales of the Wood pneumatic rotary dump and other labor-saving equipment, developed by Alexander H. Wood, and now widely used in the mining industry. Mr. Wood has been prominently connected with the American coal-min-

Even on cracking, there is no accompanying shower of glass chips and splinters to harm the eye of the wearer. 'Resistal' is the trade-name of the glass which is used in the manufacture of these goggles and masks. Its construction is made plain by the accompanying illustration. It comprises two layers of perfect optical glass, which may be either flat or curved, with a layer of celluloid interposed, the whole being welded—

WOOD EQUIPMENT TYPE OF DUMP AS USED UNDERGROUND

ing industry as consulting engineer and manager of properties for a number of years; he was also mine inspector and commissioner of labor in Tennessee. In the development and application of labor-saving equipment in the mining industry, his operations have recently been extended to the copper and iron mining industries of the Middle West, where the Wood equipment is being introduced into many of the largest mines. The pneumatic rotary dump is a well-known device and is equally adapted to the operations on the surface and underground. An entire train of ore cars may be run into it and automatically inverted, spilling the load into bins below, then rotated into position and drawn ahead, and the train will be delayed less than one minute for dumping.

not cemented—into a solid mass. The result is a crystal that has all the virtues of ordinary glass with none of its dangers or drawbacks; it has, moreover, all the strength and safety of the celluloid goggle, but, unlike celluloid, it is absolutely unscratchable, is rigid, and perfectly fire-proof. Neither is it

'RESISTAL' UNBREAKABLE GOGGLES

## NEW CRYSTAL FOR GOGGLES AND MASKS

The mine operator who is interested in 'safety first,' and also the miner himself, will be interested in a new crystal that has been developed for use in goggles and masks worn by workmen who are exposed to the hazard of flying chips or specks, dust, gas, or excessive heat and light which may jeopardize their eyesight. This has been developed by the Strong, Kennard & Nutt Co. of Cleveland, Ohio. The feature of the crystal is its remarkable resistance to breakage, its strength being such that it will withstand a hammer blow,

affected by water, heat, or cold, and the celluloid layer provides a heat-insulating medium which effectively prevents 'clouding' by the condensation of moisture. Goggles fitted with 'resistal' crystals are offered in a variety of styles to suit individual tastes and needs, and in either clear, amber, or euphos colors. The maker also stands ready to supply the crystals in special forms for use in industrial masks of all types. As a testimonial of their worth is the fact that

'resistal' goggles have been adopted for the Aviation Corps of the Army, while from the same quarter the makers have received orders for a large number of crystals for military gas-masks. The fact that the glass remains perfectly gas and water-tight, even when badly cracked, makes it ideal for that purpose.

### A FOOL-PROOF SAFETY-FIRST SWITCH

A little more than a year ago, when the General Electric Co. first marketed lever-switches enclosed in safety-first iron casings, the electrical world responded promptly to the protective advantage offered; orders exceeded expectations, and the success of the product was assured. The designing engineers, however, did not neglect further experimentation in order to better both the performance and the purpose of the switch. They have now placed in production another type which is

G. E. ENCLOSED SAFETY SWITCH

considered fool-proof. The accompanying illustration of the new switch shows not only the exterior protective casing, which is of sheet-metal, but also reproduces in phantom the working parts and the slate base. It is easy to see that the padlock at the bottom prevents outsiders from bothering with the fuses in the lower part of the switch-box. If the hinged casing is also carefully observed it will be evident that the switching lever at the upper right hand side cannot be closed while the covering over the fuses is open. It was at first thought that this interlocking arrangement would give sufficient protection, but several new conditions have gradually come to light. For instance, where two or three operators are involved it has been observed that, although one of them may throw on the switch with perfect safety, he may at the same time endanger another operator working on a machine the motor for which gets its current through the switch. To meet this condition three locks, each controlled by a different individual, may be used, and all operators may be kept thoroughly in touch with what is going on. By special order these switches may be provided also with spring catches, which must be pressed down while the switching lever is moved.

Both hands are thus required to switch the electricity on or off, and further safety is achieved. Because this new development is so thoroughly 'fool-proof', modern practice makes its use advisable wherever 'front connected' knife-switches are required.

### COMMERCIAL PARAGRAPHS

MARK R. LAMB has received an order for a copper-flotation plant from South America, and will ship an Oliver filter as a beginner, in December.

THE WESTERN UNION TELEGRAPH Co. announces that the Mexican and the Central & South American Telegraph companies will, effective December 1, 1917, reduce the rate to Central America, except to British Honduras, six cents per word; to Argentine, Bolivia, Chile, Colombia, Ecuador, Paraguay, Peru, and Uruguay, 15c. per word; and to the republic of Panama, from 8 to 13c. per word, depending upon the station of the origin.

THE SULLIVAN MACHINERY Co. announces that Wallace T. Roberts, formerly sales engineer for that company in lower Michigan, northern Ohio, and northern Indiana, has been appointed district manager at Denver. He succeeds Capt. Matt. R. Blish, of the Ordnance Department, U. S. A., who has been acting manager at that point since May 1917. George W. Blackinton, who had been manager at Denver previously to May last, is now a Captain commanding the 3rd battalion, 351st infantry of the National Army at Camp Funston, Kansas.

THE CHICAGO PNEUMATIC TOOL Co. has established a direct factory-branch at 627 Howard street, San Francisco, where it will aim at all times to carry a complete stock of Little Giant motor-trucks, convert-a-cars, Duntley hydro-pneumatic generators, air-compressors, fuel-oil engine air-compressors, fuel-oil engines, gasoline and distillate air-compressors and engines, rock-drills, jackhammers, portable mine-hoists, together with a large stock of repair-parts, which, in connection with the service-station will permit much better facilities to be offered than heretofore.

THE PARAFFINE PAINT Co. of San Francisco, under authority from the Commission of Corporations of California, has re-organized as The Paraffine Companies, Inc. The plan calls for the issue to the stockholders of the various formerly associated companies of preferred stock, the par value of which is equal to the book value of their present holdings, based on tangible assets. The common shares are being issued on a basis which is estimated to yield 10% for the year 1918 after the preferred stock requirements have been met. The company is also permitted to issue 1000 shares of common stock to R. S. Shainwald, the president and general manager of the company, for services rendered.

L. F. Hamilton has resigned his position as advertising manager for the NATIONAL TUBE Co., effective December 1, to accept a similar position with the Walworth Manufacturing Co. of Boston. This is the company that acquired the Kewanee works from the National Tube Co. on August 1. Mr. Hamilton has been identified with the exploitation of Kewanee products during all of his business career, so, in a sense, this is a continuation of his former activities rather than a change. After the usual academic training, Mr. Hamilton matriculated at the University of Illinois and became connected with the Western Tube Co., advancing from the claim-department to that of secretary to the sales manager, and thence to the position of advertising manager for the National Tube Co., from 1908 to 1917. He was a prominent factor in the success of the Kewanee union, Shelby tubing and National pipe. He is succeeded by W. L. Shaeffer, his former assistant, who, by reason of his training and experience, is thoroughly fitted to carry on the work of his predecessor.

## TABLE OF CONTENTS

### EDITORIAL

	Page
NOTES .....	883

MINE TAXATION .....	884
---------------------	-----

Intricacy of the Act imposing income and excess-profits taxes on mines; National City Co.'s digest of the war-tax; explanation of the method of estimating the taxes to be paid; probability of litigation over the Act. *M. & S. P., December 22, 1917.*

THE MAKING OF AN AMERICAN.....	885
--------------------------------	-----

Interview with Anthony F. Lucas; relation of oil-production to mining as an art; contributions to mining methods by Mr. Lucas; experiences in financing an enterprise based on advanced conceptions of geologic relations; the discoverer of oil at Spindle Top profited little by his achievement. *M. & S. P., December 22, 1917.*

### ARTICLES

ANTHONY F. LUCAS, AND THE BEAUMONT GUSHER	
---	--

AN INTERVIEW. BY T. A. RICKARD.....	887
-------------------------------------	-----

Born in Dalmatia, 1855; became second lieutenant in Austrian navy; settled in America in 1879; mining salt in Louisiana, 1893; developed new methods of mining the salt; study of salt-domes in Gulf Coast furnished basis for interpretation of the significance of the dome at Beaumont, Texas; adverse reports by geologists; persistence resulted in the Beaumont gusher. *M. & S. P., December 22, 1917.*

### MINING IN UTAH

BY BENJAMIN F. TIBBY.....	895
---------------------------	-----

Coal production and transportation; oil-seepages around Great Salt lake; distillation of oil-shale; checking of lead production; efforts to secure Government aid to sustain the silver market; potash plant at Marysville destroyed; copper mines and output. *M. & S. P., December 22, 1917.*

A FLOTATION PATENT.....	899
-------------------------	-----

Walter A. Scott's method of introducing oils in form of vapor with the air; results in oiling the bubble-films without loss of oil; Pat. No. 1,246,665. *M. & S. P., December 22, 1917.*

SPONGE IRON IN CALIFORNIA.....	901
--------------------------------	-----

Experiments at Anaconda in the making of sponge iron for precipitating copper; Catalonian method; new system developed by Herbert Lang; ore briquetted with heavy oil and then oil-fired. *M. & S. P., December 22, 1917.*

PHOSPHATE ROCK .....	901
----------------------	-----

Distribution of phosphate rock; ability of America to supply of the world for a millennium. *M. & S. P., December 22, 1917.*

SEARLES LAKE POTASH.....	902
--------------------------	-----

Statement by Lord Harris concerning the status and operations of the American Trona Corporation. *M. & S. P., December 22, 1917.*

COMPENSATION LAW IN CALIFORNIA.....	902
-------------------------------------	-----

*M. & S. P., December 22, 1917.*

MINING COMPANIES AND EXCESS TAX.....	903
--------------------------------------	-----

*M. & S. P., December 22, 1917.*

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.  
Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bldg.; New York, 3514 Woolworth Bldg.; London, 724 Salisbury House, E.C.  
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries in postal union, 25s. or \$6.

## Large Ball-Mill Plant Driven by G-E Motors

This notable installation of forty-eight electrically driven Marcy Mills at the Inspiration Consolidated Copper Company, Miami, Arizona, must operate 24 hours a day for long periods.

For this, one of the largest installations of its kind in the world, G-E 225 h.p. induction motors were selected. These motors have high efficiency—so important for long period operation—and ample starting torque.

Practically standard construction was selected for these motors, and the selection has been justified during the last two years by an operating record which has been successful in every respect and the basis for large repeat orders.

Hundreds of grinding mills are driven by G-E motors. Among those using these motors are the Calumet & Hecla Mining Company, the Anaconda Copper Mining Company and others equally well known.

**C**HRISTMAS greetings to our brave boys in the trenches and to the gallant lads that are preparing to go over the top in the coming year.

**T**HIS Christmas is ironical. Jerusalem has been captured from the Moslem despite the German guns mounted in Bethlehem, and bombs have been thrown on motor-boats patrolling the Jordan. The irony is that of the iron cross on which christendom is crucified.

**R**EFERRING to developments at Packard, Nevada, we are informed that our local correspondent was misinformed concerning the true conditions, which are that a recent examination of the Rochester Combined property justifies the early completion of the mill and that the recent shut-down was due to temporary delays in financing the enterprise.

**P**RELIMINARY estimates indicate that the production of copper in the United States for 1917 will be about 150,000 tons less than in 1916, but about 150,000 tons more than in 1915. In 1916 the output was 2,311,000,000 pounds of copper refined in the United States; of this, 1,928,000,000 pounds was derived from domestic ores. The American increase was nearly 80% and the production represented 75% of the world's total output. The normal increase is between 6 and 7%. In 1913 the world's output was 1,100,000 tons. Now, despite all the hindrances to industry, it is about 30% more.

**I**N a recent issue of the 'South African Mining Journal' we note a letter from Mr. J. S. Curtis, known to American geologists as the author of the Eureka monograph, in which he corrects sundry careless statements crediting Mr. John Hays Hammond with being the originator of 'deep-level' mining on the Rand. As a matter of fact the South Reef was struck in the Village Main Reef shaft about the time when Mr. Hammond first arrived at Johannesburg. The Village Main Reef was a deep-level enterprise on the dip of the gold-bearing seams of banket that were being mined by the City & Suburban and Jubilee companies. The participation of Cecil Rhodes and others in deep-level projects came after this discovery—of 9-oz. ore, 12 inches wide—had been

made on the initiative of Mr. Curtis in the Village Main Reef shaft.

**R**UMORS are current that the Department of Mines in British Columbia is considering the idea of discontinuing the publication of the annual report of the Provincial Mineralogist, Mr. William F. Robertson. We hope that this is untrue, for it would seem to us that any such step would be a blunder. The annual reports of the Provincial Mineralogist are recognized as the most reliable sources of information concerning the mining development of British Columbia and to them the public outside British Columbia is accustomed to turn for reliable guidance in such matters. We are surprised to learn that these reports are not fully appreciated at the place of their origin.

**E**DITORS have been honored by being joined recently by Mr. Taft, who has followed Mr. Roosevelt in his work as a publicist in print. It is greatly to the gain of journalism that men of such character and distinction should use it as a means of exerting influence. Among others of the fraternity, we note that Lieutenant J. L. Gallard of the 'Financial Times,' London, has been wounded at the front and that Captain Clem D. Webb, formerly of the 'South African Mining Journal,' has greatly distinguished himself. He and his son Lieutenant Stuart Webb, were decorated with the Military Cross on the same day. Captain Webb has four sons in the British Army, and other editors will join us in friendly envy of the record that he has made.

**Y**ESTERDAY evening, walking to the trans-bay ferry, the present writer saw a man spill some potatoes out of a paper bag, which had become torn by the excessive weight. The potatoes fell on the sidewalk; the owner, evidently annoyed by discovering that his paper bag was no good, allowed the remaining potatoes to fall out and did not take the trouble to collect them. For several minutes enough potatoes to make a meal for two families lay unclaimed and unheeded; even the newsboys seemed unaware of their opportunity; finally a man stooped to pick them up and we helped him to collect them. What would happen if such a thing occurred in

a thoroughfare in Belgium, Poland, or northern France, or even in Germany or England? The eagerness to get hold of such excellent food would precipitate a riot, and the man that would not take the trouble to recover it would be deemed a crazy fool.

**P**LATINUM, a metal much needed in chemical laboratories, has become scarce, owing to the interruption of supply from the Ural mountains; therefore the shipment of 21,000 ounces that arrived from Vladivostok last week was most welcome. It is interesting to note that Mr. Norman C. Stines, a Californian, the manager of the Sissert copper mine, was responsible for collecting all this platinum, having been attached to the military staff of the American Embassy at Petrograd so as to obtain facilities for the purpose. Having collected the platinum by purchase at various mines, he handed it to Mr. F. W. Draper, of the Verk Isetz copper mine, and he brought it to the United States by way of the Siberian railway, Vladivostok, and San Francisco. Our readers will recall Mr. Draper's excellent article on the Kalata plant appearing in our issue of September 1, 1917.

**O**N another page we give the text of a patent obtained recently by Mr. Walter A. Scott, formerly of counsel for the Miami Copper Company and James M. Hyde in the litigation with Minerals Separation. It would appear that the learned lawyer has been so much in the atmosphere of flotation technology that he felt impelled to try his own hand at devising a method of operation. The result is patent No. 1,246,665; this reminds one of the so-called bubbles patent of Sulman & Picard, No. 793,808, in which "the pulp is submitted to the action of a current of air or other gas bubbles, the air or other gas being first suitably charged either with the vapor of a volatile oil, such as petroleum of low boiling-point, or with the spray of any other suitable volatile or non-volatile or fixed oil or the like [what verbiage! why not delete eight out of the last nine words?]. The oil may be sprayed or reduced to a state of such fine division that minute globules of the same can remain temporarily suspended in an air or other gas current by the use of any suitable spraying or atomizing device and the air-current introduced into the ore-pulp, preferably at the bottom, by means of a pipe or pipes provided with suitable perforations or by other suitable contrivance. The minute oil globules or the condensed vapors or volatile oils [what happens to the "non-volatile oils or the fixed oil or the like"?] attach themselves to the metalliferous particles in preference to the gangue." Mr. Scott uses a volatile oil—he dispenses with the non-volatile, the fixed, or the like—and appears therefore to know what he is about, for he says that the oil performs its useful function not in the ore-pulp as a whole but only in the film enclosing the bubbles of air. Thus he impregnates the air with the gasified oil and consequently all the oil is introduced as part of the gaseous volume that makes the bubble; accordingly none of the oil is dispersed

through the pulp, and none of it can fail to perform its proper function, for in condensing it necessarily collects as a film around the bubble. The oil is heated by a steam-coil so that it is vaporized in the presence of a current of air under pressure, the resulting gaseous mixture of oil and air being forced through the porous bottom of the vessel containing the ore-pulp. As distinguished from the method of 793,808, Mr. Scott uses heat to vaporize his oil and so avoids the need for a "spraying or atomizing device." Successful experiments, we understand, have been made at Ray, by means of an injector into which hot oil and air under pressure are admitted, the injector being then placed on the bottom of the flotation-cell. In this way, as in Mr. Scott's patent, the intensive distribution of the oil required to bring it in contact with the mineral particles is performed without the aid of mechanical agitation and the oil is introduced to the mineral through the medium of the bubble-films in contact with which the flotation is effected.

## Mine Taxation

The owners of mines, whether individuals, syndicates, or companies, have to face an increase of taxation incidental to war. In addition to the customary State, County, and Federal taxes, they will have to consider the payment of an extra income-tax and an excess-profit tax, in amount sufficient to modify their policy and mode of operation. The Act imposing the special war-tax is expressed in terms that are intricate and confusing. When the Treasury Department has decided a few doubtful cases, it will be known what is the intent of the enactment, but until then each man, assisted by those versed in official ways, must interpret for himself. In default of other guidance he will do well to study the pamphlet issued by the National City Company of Washington. In this digest of the war-tax it is stated that "the invested capital and net income for the taxable year and the average rate of income for the pre-war period (1911-1913 inclusive) must first be determined, according to the technical rules prescribed in the Act." Therefore first ascertain the rate of income earned on the invested capital, by dividing the net income by 1% of the capital. If the rate is less than 7%, there will be no excess-profit tax. If the rate earned is not over 9%, and is not greater than the average rate for the pre-war period, there will be no tax. If the rate earned is over 9%, or is greater than the average rate for the pre-war period, but does not exceed 15%, there may or may not be a tax, depending upon whether the excess over 9% or over the pre-war rate exceeds the specific exemptions allowed, namely, \$3000 for corporations and \$6000 for partnerships or individuals. If the rate earned does not exceed 15%, then income equivalent to the pre-war rate (between the limits of 7 and 9% as specified above) is exempted. If the pre-war rate was 7% or less, multiply the invested capital by 0.07 (7%); if the pre-war rate was 9% or more, multiply the capital by 0.09 (9%);

if the pre-war rate was between 7 and 9%, multiply the capital by the exact percentage of pre-war income. Deduct the exempted income, computed as above, from the net income for the year. From the remainder deduct the specific exemption of \$3000 for a corporation or of \$6000 for partnerships and individuals. After these deductions, the remaining income, if any, will be taxed at 20%. Pay it cheerfully. Next, where the rate of income exceeds 15%, the tax on this excess is additional to the tax on the first 15%, thus

Next 5% or less between 15 and 20%	is taxed	25%
“ 5% “ “ “ 20 “	25% “ “	35%
“ 8% “ “ “ 25 “	33% “ “	45%
Remaining income in excess of 33%	“ “	60%

To determine the total tax, it is necessary to add the tax on the first 15% to the tax on each of the higher grades that the income reaches; but since the rates on the excess over 15% are all in fixed ratio to the income, without any deductions, it is possible to tabulate, for each enterprise, the aggregate tax on the excess over 15% expressed in percentages of the capital. To do this the first step is to define 'invested capital'. This may be (1) actual cash paid in; (2) the cash value of tangible property paid in (not exceeding in any event the par value of stock or shares issued therefor) at the time of payment, but if paid in prior to January 1, 1914, then the cash value on that date; (3) surplus, paid in or earned, and undivided profits, used or employed in the business, exclusive of undivided profit earned during the taxable year. Next, what is 'net income'? It is gross income less (1) expenses of maintenance and operation, including rentals, (2) losses sustained and charged off during the year, not compensated by insurance or otherwise, (3) depreciation, an allowance for wear and tear of plant and machinery, (4) interest paid on indebtedness, (5) taxes paid within the year, except income and excess-profit taxes, (6) depletion of resources. It would be a simple matter to make these subtractions if words meant the same thing to everybody. 'Depreciation' is interpreted variously; by improvident operators it is ignored; by conservative operators it is fully appraised annually. 'Depletion' will cover the exhaustion of ore-reserves, but here again individual practice differs widely and the tax-collector will not only fall back on awkward precedents but he may quote the Supreme Court's decision of last February whereby allowance for depletion was limited to 5%—a proportion ridiculously low in view of the short life of most metal mines. Unfortunately it is a fact that the book-keeping of mining companies is anything but scientific, that is, it fails to recognize sundry basic facts, of which two, at least, have been ignored persistently by promoters, who paid no attention whatever to the opportunity given to an unphilosophic tax-collector. (1) A mine is a wasting asset. (2) The dividend from a mine is not income, but a return of capital, until such time as the capital has been reduced. A mine has no goodwill; when exhausted it is a mere hole in the ground surrounded by dumps that

disfigure the scenery. The general ignorance of the economics of mining, not only among miners themselves, but among the tax-collectors that now take advantage of this fact, is a serious obstacle to the correct incidence of taxation. It appears likely that reliable definitions of such fundamental terms as 'capital', 'income', 'depreciation', and 'depletion' will not be available until the Courts have handed down a large number of decisions. Much litigation may ensue, for the law is darkened by technical obscurities. Even a constitutional question could arise, because under the Act property may be taken without recompense, but no American cares to raise a constitutional question in time of war; the average citizen is willing to bear his part of the cost of the War, while disliking intensely to be mulcted for more than his proper share. The excess-profit tax is a piece of legislation that weighs inequitably upon many forms of mining; it was enacted in a hurry and will call for a great deal of patience and long-suffering on the part of the mining community. The one clear point in the law is the exemption of Senators and Congressmen from the incidence of the tax; that is a feature that calls for instant correction.

## The Making of an American

In the interviews previously published, covering the careers of distinguished members of the profession, we have had to deal with the mining and metallurgy of gold, silver, copper, and lead. In this issue we give our readers the record of a conversation with an engineer famous for his success in exploring for oil. It is a curious fact that people will talk of the finding and winning of oil as if it were not 'mining'; in an interesting controversy between two distinguished engineers it was contended by one of them that the exploitation of an oil-field did not come under the definition of 'mining.' Presumably the liquid condition of mineral-oil and the fact that it is pumped, when it does not gush, suggests the notion that the art of extracting it from the earth is different from digging for ore. One might as well refuse to recognize hydraulicking and ground-sluicing as belonging to the ancient art, or, if that be stretching the analogy, then we may compare the winning of the liquid oil with the extraction of salt by solution in water, as a brine, or the raising of sulphur by melting it first with hot water. On the contrary, the finding of oil involves a more direct application of geology than ordinary metal mining, and the exploitation of an oil-bearing sand entails the application of engineering in its simplest and most direct forms, as we shall see in the interview with a notable exponent of this branch of technique. All those whose careers have been reviewed recently in these columns happen to be Americans of British descent, that is, they connect themselves immediately or remotely with English, Scottish, or Irish ancestors; and only one was not born in the United States. Our victim this time is Anthony F. Lucas, a Dalmatian by birth, a Montenegrin

by origin, an Austrian by forced adoption, and an American by choice. Starting as a cadet in the Austrian service, he happened to visit this country and became interested in the mechanical engineering of a lumber camp. Soon after arrival he felt the pull of this great democracy and decided not to return to his Adriatic home, which he re-visited only once, on the occasion of his honeymoon. Whatever the peccadillo that caused him to leave the Austrian navy it is clear that he was not afraid to renew acquaintance with his former compatriots. He suggests that his immunity from arrest was due to the presence of his bride, and from what we know we can well believe that this charming and accomplished Texan lady completely disarmed any official that might have thought of making trouble. After some experience of metal mining in Colorado and elsewhere Captain Lucas went to Louisiana to explore for salt. He describes the chamber-and-pillar system of mining adopted by him and explains how it is necessary to use brine in drilling for salt, in order not to enlarge the bore, as would happen if fresh water were used. He found an enormous mass of salt for the celebrated actor, Joseph Jefferson, who took a philosophic or grandpaternal view of the discovery, deciding to leave it for the benefit of his descendants. The salt was 1750 feet thick. Here we may mention the fact that scientific men are not yet agreed as to the origin of the masses of salt found in Louisiana. A post-Cretaceous movement of a deep-seated magma produced results not fully understood, because the igneous rock did not reach the surface save perhaps at one point on the Gulf Coast. It is supposed that the heated solutions ascended through the disturbed strata, which contained salt and gypsum. The solutions dissolved the salt. The force of crystallization enlarged the openings and the accretion of the saline deposits produced a doming of the strata. The final salt deposit is not a horizontal bed, neither is it a simple lagoon sediment or precipitate. Captain Lucas published a paper on his exploratory work at Belle Isle in the September 1917 bulletin of the American Institute of Mining Engineers. Reference may also be made to an earlier paper by him on 'Rock Salt in Louisiana' in the transactions of the Institute for 1899. At Belle Isle, on the shore of the Gulf of Mexico, he discovered not salt only, but sulphur and oil as well. Indeed, the subsequent exploiters of this deposit found that the salt was so impregnated with oil as to be unmarketable. The association of these three mineral products—salt, sulphur, and oil—is most interesting to the geologist, but space will not permit us to linger on it. We must hasten to the big event. Captain Lucas had now been prospecting and geologizing along the Gulf Coast for five years; going inland, and exploring the coastal plain, he detected a mound at Beaumont in Texas. This mound indicated a dome, and the escape of sulphurous gas suggested that either sulphur or oil would be found underneath. So he leased the ground and started to drill, using a rotary tool, and therewith going safely through a layer of quicksand. At 575 feet he penetrated oil-sand, but almost immediately lost the well by collapse due to

gas. He had saved a sample of the oil and with that sample set forth on a pilgrimage to obtain financial assistance. He tells us how he interested several well-known men and how others came to see him at Beaumont. He had spent all his money and was facing disaster at the moment when he thought he had justified his theory of dome structure. Experts of the Geological Survey and of the Standard Oil Company came to pat him on the back and dissuade him from so visionary an enterprise. He persisted, and at last obtained financial aid from Mr. J. M. Guffey. After spending \$6000 more he struck oil and no mistake, a flood of oil that gushed forth with such violence as to hurl 1100 feet of casing and the head-blocks of the derrick out of sight. The oil gushed at the rate of 100,000 barrels per day; it made a 30-acre lake that overflowed to the sea, endangering both railroads and shipping. Thus the man that a few days before was facing bankruptcy now saw his wealth running to waste down the bayou. Then came the supreme test of engineering: to curb and control the flow of oil. Captain Lucas accomplished the feat by means of an ingenious device, which he describes, and thereby avoided the necessity for paying \$10,000 to the woman that sent him a 90-cent collect telegram offering to do it by aid of absent treatment. It must have been more pleasant to receive the congratulatory message from the eminent oil expert, but that gentleman did not liquidate his obligation thereby, for the discouraging advices of sundry 'savants'—that is what the daily press calls them, we believe—caused him, as he says, to "sell his birthright for a mess of pottage." The Lucas, or Spindle Top, gusher has produced over 50 million barrels of oil without giving a proportionate reward to the discoverer; but he had the satisfaction of proving his geological hypothesis, and later he used his experience and reputation to get into some better-paying enterprises, and so, it is pleasant to record, he did not go unrecompensed. That recompense was not all in standard coin, for he acquired two things not measurable in common units; he gained fame and friends. His ideas and his work won him many friendships among geologists and engineers, who appreciate, among other things, the outstanding fact that he never succumbed to the importunities and blandishments of those that wanted to use his name for oil promotions. A big man physically, Captain Lucas has a big warm heart, spontaneously sincere and generous. Wholehearted in all he does, he is enthusiastic, even impetuous. Just now he is so keenly interested in the War and in the success of the great cause for which the Allies are battling that he will endure no half-hearted patriotism or tepid sympathy for the wrongs of Belgium or Serbia, for example. The young Dalmatian that rejected the Austrian service to become an American has been splendidly consistent, not only in becoming a supremely useful citizen of the United States, but in sealing his devotion to the flag of his adoption by giving a fine upstanding son to the American army now fighting under General Pershing in France. The younger Anthony sets the seal on his father's Americanization.

SPINDLE TOP, TEXAS, IN 1902

## Anthony F. Lucas, and the Beaumont Gusher

AN INTERVIEW. BY T. A. RICKARD

*Capt. Lucas, you are of European origin?*

Yes, Sir, I was born in Dalmatia, Austria, in 1855. My forefathers, however, were of pure Montenegrin blood.

*What was your father's occupation?*

He was a ship-builder and ship-owner on the island of Lesina.

*So you had an interest early in engineering. What was your education?*

My family moved to Trieste, where I was educated in the high-school and after that in the Polytechnic of Gratz; at the age of 20 I was graduated as an engineer.

*After graduating, what did you do?*

I entered the Austrian navy as a midshipman and was promoted to second lieutenant. At that time an unpleasant incident made me very much dissatisfied with the rigor of the service, perhaps because of my Slav origin, so that I was glad to accept an invitation to pay a visit to an uncle of mine in this country. For that purpose I obtained a six months' leave of absence and came to the United States. That was in 1879, when I was 24 years old.

*I have an idea that your father's name was not Lucas?*

My father's name was Luchich. The reason of the change was that when I came to America on a visit to

my uncle, my father's brother, as I have stated, I found that my uncle had adopted the name of Lucas, owing to the difficulty that Americans had in spelling and pronouncing Luchich. So, for the time, expecting to remain only three or four months, I permitted myself to be addressed as Lucas. When I decided to reside in the United States I retained this modification of the name.

*What happened to make you remain?*

An engineering problem was offered to me during my stay in Michigan. At that time Michigan was a lumber country, and Saginaw, where I resided, was its centre. A gang-saw was needing some improvement in design, and when asked if I could do it I agreed with pleasure, completing the design satisfactorily to the mill-men. Later on I was asked to supervise the erection of this gang-saw. Then, just as the end of my leave was approaching, I was offered a flattering engagement, which, after some consideration, I accepted, asking, however, for another six months' leave. At the end of that time I had made up my mind to become an American citizen; I made proper application and completed the change of allegiance by obtaining my final papers four years later at Norfolk, Virginia, on the 9th of May, 1885.

*Did you ever return to Dalmatia?*

Yes, in 1887, nearly ten years after, on my wedding

journey. My wife and I went to Trieste, Fiume, and Pola, and to the place where I was born, Spalatro, which, by the way, is an old Roman city erected by the emperor Diocletian. Although I had some fear of contact with the rigor of the Austrian law, I was not troubled. On the contrary, I was entertained at Pola by the officers of the Navy and ascribe my immunity to having good friends, but perhaps it was Mrs. Lucas' charm of manner or because she was unmistakably American. I was abroad one year.

*On your return from your wedding journey, where did you settle?*

I made Washington my home, and entered the profession of mechanical and mining engineering. First I went to the San Juan region in Colorado and prospected for gold, with some little success, but after two years I returned and began to look around for a good opening in the mining industry, and became employed as mining engineer at a salt mine in Louisiana, in 1893, at Petit Anse, where I practised the engineering and mining of salt for three years.

*What was the nature of the exploitation?*

I found the salt deposit only 20 ft. below the drift-soil, and the shaft 180 ft. deep. Mine and mill were in very bad condition owing to the fact that water had found its way into the mine and caused a large cave. The mill was antiquated. It required constant care to check the caving and water in the mine, and the ravages of the salt on the mill machinery.

*Was there any other technical feature worth mentioning?*

Yes, the system of mining. I opened long drifts in virgin ground, adopting an overhead method of mining, feasible only under such conditions. A gallery was started with a 7-ft. under-cut, 50 to 60 ft. wide, and from 200 to 300 ft. long. After clearing away this broken salt in tram-cars the second under-cut was started, 18 to 20 ft. in height, and when this was cleared the final mining was begun with the aid of threepod ladders upon which light hand-drills were placed, drilling batteries of holes 10 ft. deep. Thus six or eight holes shot down hundreds of tons of salt. This method proceeded until, by the time the height reached 50 ft., no more ladders were needed, owing to the increased volume of the salt. The roof, of course, was arched toward the 40-ft. pillars left standing. Suspiciously loose slabs of salt were pried down or shot down to make the roof safe, and by the time the men had finished there remained a mass of from 3000 to 5000 tons of mined salt ready to be trammed and hoisted to the mill. By this method not a board or stick of timber was used or needed.

When the mining in this chamber was completed another under-cut was started laterally and we thus had always in reserve one or more chambers of mined salt, say, 60 ft. wide, 60 ft. high, and 200 or 300 ft. long, each containing from 3000 to 5000 tons, at a cost of less than 14 cents per ton of salt mined. The salt was of unusual purity, 98.5 to 99% sodium chloride, the remainder being gypsum.

*What did you do next?*

During the three years that I was employed there I became acquainted with Joseph Jefferson, the famous actor, who had an island known by his name, a few miles off Petit Anse. Mr. Jefferson was anxious to bore for water, and had actually given a contract, but the contractor found difficulties in complying with the terms of his agreement, owing to the boulders and sand through which he had to drill. At this time Mr. Jefferson asked me if I could see my way to help the contractor. Although employed by the salt people, I accepted eagerly, and helped by introducing a method of driving the casing and succeeded in assisting the contractor to pass through the gravel bed. About 100 ft. deeper we struck what appeared to be solid rock, but upon analysis, it proved to be an enormous bed of salt. Then Mr. Jefferson asked me if I would continue the exploration in an advisory capacity, which I did. I purchased a diamond-drill from the Sullivan Machinery Co., of Chicago, and drilled to the depth of 2100 ft., still in salt, a total thickness of 1750 ft. of salt, without encountering any foreign substance.

*What did you do with this discovery?*

During my operations at Jefferson island rumors were spread by uncharitable persons that I was fooling Mr. Jefferson. I was asked, if I claimed I had so much salt, why did I haul carloads of salt from Petit Anse to Jefferson island. It is true I hauled several carloads of waste salt, but only to use as brine with which to bore, so that it would not enlarge the bore excessively. You will understand that if I used fresh water I would have dissolved the walls of the bore. Owing to this malicious gossip, Mr. Jefferson asked me if I had found enough salt, as he wanted to stop. I replied that I had salt enough to salt the earth; I was proceeding nicely, and was anxious to find the floor of the salt, when he stopped me at 2100 ft., thus balking a possible study in geology, for I wanted to learn on which geological formation this salt was resting.

*That must be an enormous mass of salt, do you know of any larger?*

The salt mines at Wielitzka, in Austrian Poland, are worked at over 3000 ft. in depth, and the potash salt mines in the Stassfurt district of Germany are worked to over 1500 ft. in depth, but the salt deposits of our Coastal Plain now surpass both of those in quantity and extent.

*Probably you had an idea of mining from that floor upward?*

No, because I found on subsequent borings that the salt mass was in one locality only 81 ft. from the surface, and to mine at a depth below 2100 ft. would have been costly and unnecessary when one could mine at a reasonable depth, say, 500 ft., and leave between 200 to 400 ft. of solid salt for a roof. Mr. Jefferson, however, decided to leave this deposit to his grandchildren, and I heard only recently that it has been sold.

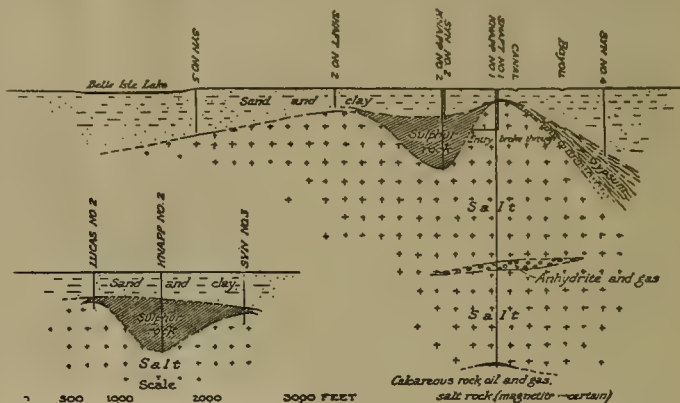

*So, Captain, you had to make another start?*

Yes; in the meantime I had examined a small island known as Belle Isle, on the Gulf coast, one of a series of five islands now well-known for their salt deposits, and contracted with the owner to explore Belle Isle for minerals on my own account. I undertook to explore the land by perforations. Four wells were drilled for salt,

I did not have the money. The island was purchased later by the American Salt Co. and I received a consideration of \$30,000 in bonds and \$5000 in cash. This led me to study the accumulation of oil around salt masses, and I formed additional plans for prospecting other localities. Thus I began my investigations into the occurrence of oil on the Coastal Plain. That was in 1897.

CRYSTAL OF SALT SHOWING INCLUSION OF OIL AND GAS

CROSS-SECTION OF RECENT WELLS, SHOWING THE POCKET OF SULPHUR, AT BELLE ISLE

discovering thereby a deposit not only of salt, but of sulphur and oil as well.

*How were these three minerals related in space?*

The first well was a miss; the second well penetrated a 66-ft. bed of sulphur, and below that I discovered the matrix of a salt dome. By further boring I encountered oil-sand at a depth of 115 ft., and deeper down, at about 800 ft., I discovered a strong flow of petroleum gas. Resting there, I completed my contract, and acquired title to one-half of the mineral resources of the island.

*You then proceeded to exploit the oil?*

I fully expected that the American Salt Co. would put me in charge of their operations, but they did not make me the offer and I did not make any request. They sent a New York salt man and began large operations, involving over two million dollars.

*Which of the three minerals did they exploit?*

Salt only. Unfortunately, the method of mining salt in Wyoming county, New York, was not adapted to the deposits of the Coastal Plain. They started sinking a large working shaft where it showed nearest to the surface, at 115 ft., without having previously sounded the

ROOF OF CHAMBER IN THE WEEKS SALT MINE

deposit by boring to ascertain its conformation and purity. Salt is much in demand from the meat-packers of the interior, but this particular salt was unmarketable because it was impregnated with oil and gas. In bailing out the salt-cuttings and dumping them on the floor, they would explode like pop-corn. This was caused by the sudden liberation of gas coming in contact with the air. In my exploration of the various salt deposits of the Coastal Plain this was my only experience of the kind.

*What did the contractors do?*

They sank to a depth of 250 ft. and started driving toward the interior of the deposit, searching for purer salt. When I heard what they were doing, I telegraphed at once asking if the drift was in the right direction, and if they had sounded with a diamond-drill in that direction. Unfortunately, the next news was that they had passed through the salt and had penetrated quicksand. The mire of the marshes drove them out and they barely had time to save the men, thus losing the first shaft. It proved afterward that the salt in this locality formed a depression, 500 ft. westward, although it was connected with the main dome. They started another shaft westward, but made a series of woeful blunders. The salt did not occur so shallow there and they had to go down 276 ft. before they reached it. On top of this salt they found a layer of about 30 ft. of bad quicksand through which they could not pass. They then employed an expert shaft-sinker, named Sooy-Smith, who employed a freezing process. Another unfortunate incident was that Sooy-Smith never put the brine-pipes in the salt; he stopped in this quicksand, so that when the mass was frozen, preparatory to mining, they were just as badly off and could not pass the quicksand. They spent a large sum of money, finally abandoning the effort. They then proceeded to explore for oil, and after a series of efforts gave that up. The island was sold at public auction and is now the property of the New Orleans Mining Corporation.

*That did not stop your prospecting, I feel sure. What did you do?*

I explored, meantime, Weeks island, also in Louisiana, and there discovered a magnificent bed of salt now being worked with commercial success. Meanwhile further investigation led me to proceed. I selected a point known as Anse la Butte, six miles north of Lafayette, in Louisiana. In this locality I again discovered oil and salt, but not under favorable conditions. (Since that time, however, it has produced and is still producing large quantities of oil.) So I abandoned the discovery and went to Beaumont, Texas, about 70 miles west of Lafayette. There I was attracted by an elevation, then known locally as Big Hill, although this hill amounted merely to a mound rising only 12 ft. above the level of the prairie.

*What led you to prospect there?*

This mound attracted my attention on account of the contour, which indicated possibilities for an incipient dome below, and because at the apex of it there were

exudations of sulphuretted hydrogen gas. This gas suggested to me, in the light of my experience at Belle Isle, that it might prove a source of either sulphur or oil, or both. I decided to test it therefore and leased all the ground that I could secure.

*How many acres?*

The hillock only covered 300 acres, of which I secured 220 acres; but I leased altogether about 27,000 acres in the vicinity in order to have ample scope for exploration, although this proved unnecessary, as no oil was ever found beyond the contour of the dome.

*What was your first result?*

This elevation had already been explored by three companies and none succeeded in penetrating below 250 ft. in depth.

*Why?*

Because a bed of quicksand was struck at about 200 ft. Knowing that they used cable-drilling apparatus, I decided that that must have been the reason for their failure, so I set to work with rotary-drilling tools. The rotary drill at that time was almost unknown and was only used for artesian-water wells of shallow depth on ranches and rice plantations. I penetrated the quicksand and soon realized that I was correct in my surmise of the reason why my predecessors had failed. I managed to pass the quicksand and bored to a depth of 575 ft., encountering an oil-sand but losing the well by gas collapse. I thought best, however, before proceeding with heavier rotary-drilling machinery to seek geological and financial aid, so I went to a number of capitalists and laid before them my plans and expectations; but they turned me down. I recall one instance, when a friend took me to see former Congressman Sibley, of Pennsylvania, to lay before him my project. He read me a lecture and stated that he could not participate in such a wild scheme; that unless I had a production of so many thousand barrels per day to count upon, he was obliged to decline; to which I replied, that if I had such a production I probably would not have come to see him.

*You did not abandon your quest?*

No, I went to others, for instance to H. C. Folger, Jr., of the Standard Oil Co., in February 1899. I had a bottle of the oil with me and it happened to be a bitter cold night in New York. Having my ideas on practical issues, I put the bottle out of my window in order to give it a cold test. The oil was 17° B. gravity; it did not seem to congeal at all, although I understood that the temperature outdoors was two or three degrees below zero. Happy in this test, I went to see Mr. Folger, and laid the matter before him, asking him to join me. I told him that I did not want money personally, only assistance in further prospecting and proving the field; but Mr. Folger, while he received me graciously, declined. However, he promised to send Call Paine, of Titusville, the then Standard Oil expert, to examine my scheme. Paine arrived a month later, with J. S. Cullinan, who later became President of the Texas Company. I showed them

the location of my first shallow well and the heavy oil extracted therefrom. I also explained to them my 'nascent dome' theory. It ended, however, with Mr. Paine giving me a piece of well-meant advice, to wit, that there was no indication whatever to warrant the expectation

million dollars), stating further that I had no seepages of oil, as leaders or indications, etc. I pointed to the great sulphur dome near Lake Charles, at that time in course of development by Herman Frasch, whereon a limited production of  $1\frac{1}{2}$  barrels of oil was obtained—a

heavy oil it is true and a straw for me to grasp—but no encouragement could I get from Mr. Hayes, whom I of course knew as one of the best geologists in the country. Thereupon I began to seek co-operation and financial aid from some one better fortified than myself financially. This led me to enlist the aid of J. M. Guffey, of Pittsburgh, who took my proposition up, but to whom I was obliged to relinquish the larger part of my interest in the venture. In the first well that I drilled with Mr. Guffey's money, at a cost of less than \$6000, at a depth of about 1100 ft., the oil came with a rush of over 100,000 bbl. per day. This was on the 10th day of January 1901. Next day I received a

DAMON MOUND, TEXAS

of an oilfield on the prairies of south-eastern Texas, that he had been in Russia, Borneo, Sumatra, and Rumania, and in every oilfield of the United States, and that the indications I had shown him there had no analogy to any oilfield known to him, that I absolutely had no chance, as in fact there was not the slightest trace of even an oil-escape; in conclusion, he advised me to go back to my profession of mining engineering. *That was a squelcher; did it crush you?*

I retorted by showing him a demi-john of the heavy  $17^{\circ}$  B. oil, obtained at 575 ft. He characterized it as of no value and of no importance whatever, stating further that such heavy stuff could be found most anywhere. I am, however, convinced that Mr. Paine was sincere in his advice, which naturally shook my confidence.

Another incident happened during the fall of 1899 to shatter my faith in the venture. Charles W. Hayes, formerly Chief Geologist of the U. S. Geological Survey, accompanied by Edward W. Parker, formerly Chief Statistician of the Survey, dropped in on me to see what I was doing, and I explained to Mr. Hayes in detail my deductions of possible oil accumulations around great masses of salt, etc. He also discouraged me, saying that there were no precedents for expecting to find oil on the great unconsolidated sands and clays of the Coastal Plain, pointing to the great well drilled by the city of Galveston, Texas, over 3000 ft. in depth (a big undertaking at that time and one that cost the city nearly a

telegram from Mr. Paine extending to me his warmest congratulations on my success and saying that he was coming down to see the new wonder. He little knew, however, that he and Mr. Hayes were the indirect cause of my "selling my birthright for a mess of pottage."

SPINDLE TOP, TEXAS, EARLY IN 1902

Mr. Cullinan also appeared next day and became a large factor in the Spindle Top field, realizing millions thereby, and enabling him later to organize the Texas Company, a corporation now worth its hundred millions of dollars. Mr. Guffey, with Andrew Mellon, of Pittsburgh, organized the J. M. Guffey Petroleum Co., with a capital of \$15,000. This capital was later largely increased, and later still the title of the company was changed to the Gulf Petroleum Company.

*So Guffey became associated with you?*

Yes, he was a noted petroleum operator in Pennsylvania. I entered into a contract with him that he should drill three wells, at least 1200 ft. deep, under my direction.

*Did he undertake to supply the capital?*

He undertook to stand the expense of three wells, and I was to superintend the operations. The first well, however, proved the Lucas gusher at a cost of less than \$6000. *You proceeded to work?*

I contracted with Al and Jim Hamill, of Corsicana, to drill three wells at \$2 per foot, we to furnish the casings. I took charge of the drilling and chose a site where the now famous Spindle Top, or Lucas, gusher, was developed.

*Kindly outline the events that led up to the escape of oil?*

The first casing was 12 inches, reducing the diameter finally to 6 inches. When we reached the quicksand, at about 300 ft., we began to have trouble; our drill-pipes stuck. The 6-in. pipe was relieved by going over with an 8-in. pipe, which in turn became stuck, and I, knowing that the practicable limits had been reached, was in great distress to proceed with the work. I could not sleep that night, but toward morning the thought came to me that if a boiler having a 100-lb. pressure of water could be pumped full without any water coming out, there was a reason for it, and the reason was that it had a check-valve alongside. That proved an eye-opener to me. Much excited, I hastened to see my driller and explain what I wanted. Thereupon I designed a check-valve, made out of the boards of a pine box lying in my back yard, and with openings in the centre and a small rubber belt underneath I placed this check-valve between the coupling of the casings, and thus proceeded without any further trouble.

*Did you patent your invention?*

No, at the time I had it in mind to do so but was deluged with work and incipient possibilities. If I had done so I would have realized a large amount of money.

*How did your drilling proceed by aid of the check-valve?*

The drill-hole proceeded through various layers of quicksand to 800 ft., then struck lime and sulphur for about 250 ft., to a few feet less than 1100, and while we were lowering the casing, after having sharpened the bit, the casing (which was attached with a block and five strands of 2-in. cable) began to rise, increasing in momentum until the whole casing of about 1100 ft. was shot out to an unknown height, carrying the heavy block and the head blocks of the derrick with it into the air, followed by a gush of muddy water, our own drilling-water, then by rocks and fossils, and finally gas. It then settled down to a magnificent 6-in. stream of solid oil of 23° B., rising to a height of 200 ft. That was the celebrated gusher, which ran wild for 10 days, making a lake of nearly 30 acres, which was impounded by levees that I built to confine it.

*Were you charged with damages?*

I was served notice by the railroad company and by a marine insurance company at Port Arthur and Sabine Pass that ships were endangered, as a great deal of oil had found its way to these seaports, 16 miles below on the coast, and requesting me to remove the oil. The Southern Pacific railroad company also served notice on me to remove the oil because of the danger to the tracks, etc.

*How did you control the flow of oil?*

During the ten days that preceded the closing of the well, I had innumerable offers from irresponsible people to close it for me, because some newspaper had published a statement that I would give \$10,000 to any one who would close the well. One of the offers was made to me by a woman in Illinois. She telegraphed that if I would put the \$10,000 in a bank, subject to her order, she would use her occult power to discipline nature. However, I realized that it was up to me and my men to solve the problem. In 10 days we completed the construction of a steel-rail carriage to pass an 8-in. gate-valve over the 6-in. stream of oil. At 10 o'clock in the morning of the tenth day, with the aid of block and tackle, I started to drive and drag this valve, which was woven with the iron rails, to enter this powerful stream. At the first impact when this gate-valve, which was open, came in contact with the stream of oil, the derrick, badly shaken, but still holding, began to rock, and I remember picking up one of the fossils on the ground to throw at the horses so as to urge them to faster speed, until finally the valve passed the stream of oil, which was turned inside of it. Then we screwed the valve on the 8-in. casing, and that closed the gusher. This discovery of oil led to the development of a big oilfield, which became known as Spindle Top. It has produced over 50,000,000 bbl. of oil, and is still producing.

*I hope, Captain, that you received a proper financial reward this time?*

I did, but my chief reward was to have created a precedent in geology whereby the Gulf coast of the Coastal Plain has been and is now a beehive of production and industry. Owing to the fact that Mr. Guffey and the Mellon group had a lot of money and I had not, I accepted their offer and sold my interest to them for a satisfactory sum.

*Did you stay there long?*

I severed my connection with the Guffey Petroleum Co. about six months after the Beaumont discovery. In selling to them I retained the leases that I had acquired at High Island, near Galveston, an entirely different locality, 70 miles south-west of Spindle Top. I also secured land and drilled a well for the Guffey Petroleum Co. on another dome then known as Bryan Heights, on the Gulf, some 40 miles south-west of Galveston.

*What success did you have?*

In July, 1901, at 800 ft. deep, I struck a powerful force of sulphuretted hydrogen gas, which drove my men and everybody else off the location. Unfortunately, the company neglected that discovery and it became forfeited

BURNING OF A MILLION BARRELS OF OIL AT SPINDLE TOP, TEXAS

in the next three years; subsequently it was taken up by speculators, who induced Eric L. Swenson, one of the directors of the National City Bank of New York, to proceed on the basis of positive knowledge of a sulphur bed existing there. Mr. Swenson organized the Freeport Sulphur Co. and is now exploiting it by aid of the method applied by Herman Frasch at a similar sulphur deposit, in Louisiana, by the process of melting the sulphur with hot water and forcing it to the surface by the pressure of hot air. This, together with the operations of the Union Sulphur Co., is one of the main sources of sulphur supply in the United States, and is proving most useful as an ingredient of explosives for warfare. Another well worth mentioning was located by me for the Guffey Petroleum

Co., in 1901, on a tract of land known as the Damon Mound in Brazoria county, Texas, 30 to 40 miles from Houston.

*What did you do there?*

In order to obtain leases on this dome, I had to promise the owner, J. F. Herndon, that this well should be called by his name. The well, while it did not prove a failure, for the reason that it became clogged and ruined at 1600 ft., enabled us to ascertain the existence of a bed of sulphur and oil. This dome is now producing between 5000 and 10,000 bbl. per well per day.

*So you severed your connection with the Guffey company?*

CAPT. LUCAS DRILLING ON JEFFERSON ISLAND IN 1896. HE IS SHOWN SITTING, EXAMINING A CORE JUST REMOVED FROM THE DRILL.

Yes, I had no more interest in their affair. This promising field became abandoned until about two years ago when E. F. Sims, of New York, began to prospect the dome, which is over 100 ft. high and one of the largest on the Coastal Plain. The result was to bring in gushers that are now yielding 10,000 bbl. per well. On another part of the dome there was exploited a great sulphur deposit, and deeper down an enormous mass of rock-salt to unknown depth. I got nothing out of this, except that I had bought two tracts of land at the time I was drilling, and two additional tracts of land that were presented to me by the Cave heirs of Paducah, Kentucky. These two additional tracts of land of 10 acres were presented to me with the compliments of the heirs, but, not obtaining satisfactory results, I deeded them back. These tracts of land are now worth a considerable amount of money, as they are producing large quantities of oil, but I retain the two originally purchased tracts, covering 17 acres. The land is now very valuable.

*How many years did you spend in this region?*

About three years. After that I became connected with Sir Wheatman Pearson, now Lord Cowdray, who, as you know, has large oil interests in southern Mexico.

*Please say something about your Mexican experience in oil?*

In 1902 I went to Coatzacoalcas, now known as Puerto Mexico, where I located two fields, one known as the San Cristobal, and the other as Jaltipam, on the Tehuantepec railroad. The former is producing a beautiful light paraffine oil; the latter, a somewhat sluggish heavy oil; both, however, are attractive oilfields.

*You were advisory engineer to Sir Wheatman?*

Yes, and three years after my arrival in Mexico he made me a flattering offer to remain as managing engineer in Mexico, but, owing to other aims and interests, I declined, returning to Washington in 1905. Since then I have been practising the profession of consulting engineer. My work has taken me to various parts of the world, notably Algeria, North Africa, Russia, Rumania, Galicia, and Stassfurt, besides various oilfields in the United States.

*Would you say something concerning the oil resources of the Tampico oilfield, which, I understand, today is so important a factor in supplying the Allies with fuel-oil?*

In 1903, E. L. Doheny was operating in the neighborhood of Tampico, and his success induced Pearson to obtain large concessions there, but I had no part in it. I know that the production of the Tampico field is very large, and it contains large resources of petroleum, which is now supplied to ourselves and our allied fleet.

*Have you been to any other Mexican oilfield?*

Yes, through the instrumentality of Sir Wheatman, I went by way of Oaxaca in 1903 to the Pacific coast, where the son of President Diaz and other capitalists had been operating for oil, near Port Angel in the State of Vera Cruz. There were no safe ports there and they were

obliged to beach barges of supplies towed from San Francisco, from which place they unloaded the machinery and pipes. I found them laboring under great difficulties, for the reason that they were drilling in pure syenite, which, as you know, is a crystalline rock in which engineers in general would not expect to find oil, although there were some oozes of neutral oil on the surface. This field has never produced oil. I discouraged the continuation of this work, but owing to the fact that they had already invested a large amount of money, they did not do it gracefully, and continued for another year and a half, until ultimately they had to give it up. Here I contracted dysentery, which kept me nearly a year confined to my home.

*You have not been to any of the Californian oilfields?*

No. The conditions there were not such as interested me, compared with the Coastal Plain in Louisiana and Texas.

*By the way, Capt. Lucas, you have a son?*

Yes, I have a son, born two years after my marriage. He is now a lieutenant with General Pershing's army in France.

"In studying a map of Southern ore deposits with relation to the placing of a nitrate plant it became evident that pyrite was to be found in a stretch of the mountains running from northern Georgia to central Alabama, and just when this was found, there came into the office one of the most forceful of southern manufacturers, who entered with a statement that he was looking for a place—"not under the spotlight; I'm not a prima donna; just a man's job; something somebody else would shy at."

"Why not find the pyrite ore in your southern hills?" I asked.

"Never heard of the stuff, but if it's there, and you say we need it for the War I'll get it."

That was almost literally the conversation that has led to the opening of five mines yielding 400 tons per day, which it is promised before the winter is over will be increased to a thousand tons per day; and 30,000 tons per month is more than 15 good ships could bring from Spain to our coast if kept in a continuous circle.—Annual Report, Secretary of the Interior.

PLATINUM is the object of energetic prospecting, on account of its extraordinary price, and every district from which it had been reported in the past is again being combed. The public is also being invited to buy shares in numerous enterprises that have no larger foundation than the exuberant hopes and misleading promises of promoters. The U. S. Geological Survey has recently deemed it necessary to sound a warning against the schemes of wild-cat companies that propose to exploit the gravels of the Adirondack mountains in New York. The paltry gold content and the feeble traces of platinum in these sands have led to repeated disastrous attempts at placer-mining.

THE TOWN OF GOLD HILL, IN THE DEEP CREEK MINING DISTRICT

## Mining in Utah

By BENJAMIN F. TIBBY

**COAL.** Operators report that there is a serious shortage of cars. Practically all the coal mines in the State are, at the present time, served by the Denver & Rio Grande system. The lack of cars to move coal is said to be due to the fact that the Rio Grande railroad is congested with through-freight and the physical condition of the railroad is such that unless this class of business is materially reduced the shortage of cars will continue. The independent coal-operators have made complaint to Washington regarding the situation and a member of the Federal Trade Commission was recently sent to Utah to investigate. It has been urged that the Government issue orders compelling the Rio Grande to divert freight received from the Western Pacific in favor of other railroads. At the present time, with one exception, the coal mines are working only two shifts per week. The exception is the Sunnyside, which is the only producer of coke in the State and for that reason is kept in continuous operation. Many of the metal mines are short of fuel; in several instances the railroads have commandeered coal consigned and already being transported to the mines. The coal-miners were recently granted an increase in wages that will give practically every employee an additional \$1.40 per day. A census shows that in Salt Lake City last week there were 1500 families without coal and 3000 families with one ton or less. The same condition prevails in other parts of the State. All retail coal-dealers are without stock-piles and only the favorable weather has prevented extreme suffering. A campaign for the conservation of coal is being waged.

At the Peerless Coal Co.'s mines, near Castle Gate, in Carbon county, material is on the ground for the erection of a Wood rotary-dump tippie with electrically operated shake-screens. The mine is near the Denver & Rio Grande Western railroad and one mile from the Utah Coal railroad. The Utah Construction Co. and the Wasatch Grading Co. are grading for yard-facilities and

for a 3700-ft. gravity-tramway from the main mine-entry to the railroad. The company owns 660 acres of land. There are five coal seams exposed, three of which are workable. Operations are to be confined to the No. 3 Castle Gate seam and the No. 4 seam. Each of these is 12 ft. thick. The coal seams dip at 7% but mining will be conducted in such a manner that there will be a 1% grade in favor of haulage. By January it is expected that the mine will be capable of producing 500 tons of coal per day.

**OIL.** Interest in oil is particularly keen at this time. It is reported that options are being sought on land at the north end of the Great Salt lake where oil-seepages with heavy asphaltum base have been known for some time. Conditions theoretically favorable for oil exist in the Henry mountains, and drilling is being started in this region. More attention, however, is being given to oil-shale. There are practically no oil-wells of commercial importance in the State, but there is a vast area of oil-bearing shale. The U. S. Geological Survey has estimated that Utah has 20,000,000,000 barrels of crude oil tied up in its shale, from which 2,000,000,000 barrels of gasoline may be extracted by ordinary methods of refining. It is said that there are 1400 square miles of oil-shale land in Utah. Numerous new oil-shale companies have sprung up and the laboratories at the University of Utah have been busy making distillation tests.

**METAL MINES** have been having a full measure of grief. The recent rapid decline in the price of lead has greatly curtailed output and profit from the lead mines. This, together with the smelter and car embargo, has produced a serious situation. A great many of the small operators have been forced to suspend work entirely while the big producers have cut their working forces materially. However, the mines throughout the State have had a period of exceptional prosperity due to the high metal-prices during the earlier months of the year. New de-

velopment was greatly stimulated, as is shown by the unusually large number of small producers who continue to ship even under present market conditions. After the harvest a greater number of cars will be available for ore-shipments and except for the question of metal prices, the situation is rapidly righting itself.

The smelters have lifted the embargo and are accepting an increased tonnage from week to week. Shipments from Park City totalled 2930 tons for the week ended November 30 as compared with 2721 tons the week before. Shipments from Tintic for the past week aggregated 183 cars as compared with 230 cars for the week previous and 219 cars for the week before that.

Silver is essentially a by-product in the Utah mines, no strictly silver and but few gold-silver mines being in operation. For that reason the uncertainty of silver prices is not so vital, although in the case of the lead producers it is decidedly important, especially in view of the present lead quotations. A meeting has been called for December 4 by the Salt Lake chapter of the American Mining Congress. Representatives of the mining industry from all the States west of the Rocky Mountains, except California, are to attend. Measures are to be adopted for bringing before Secretary McAdoo the necessity for sustaining the silver market by urging Government regulation of price at some figure above the present quotation of 85 cents. The uncertain interpretation of the War Excess Profits Tax, as applied to mines, will also be considered.

There have been a number of important developments in the American Fork district. The Pacific mill is handling 200 tons of ore per day and is shipping a 30-ton car of concentrate every third day. Crude ore is also being mined and sent directly to the smelter. The Miller mine, under lease to George Ryan, has opened a body of galena ore 160 ft. below the stope from which the Tyng brothers shipped over \$750,000 worth of ore several years ago. The new strike is just above the Lady Annie tunnel and occurs along a well-defined fissure striking NE-SW, which is characteristic of the mineralizing fissures of the district. The ore is galena carrying 25 to 47 oz. silver and 30 to 60% lead. The high-grade streak is from 18 to 24 in. wide. The lower-grade ore appears to be an impregnation of the blocky shale by the galena and occurs on both sides of the fissure. There is little oxidized material in the vein, indicating that below the limestone there has been but little alteration of the primary sulphides. The ore occurs about 250 ft. above the zone in the quartzite that has proved to be heavily mineralized in the Pacific and points to a continuation of the Miller fissures into the underlying quartzite. Work is being carried on at the Whirlwind, Beddmeier & Borussia, Yankee, Bay State, Globe, Earl Eagle, Belorophan, Bog, Silver Lake, and South Park mines. Small strikes have been reported from several of these properties and nearly all are making irregular shipments. A late fall has helped materially in carrying on new work.

Encouraging reports continue to come in from the

Deep Creek region and Tooele county. During the month of September 117 cars of ore were shipped over the Deep Creek railroad from the Gold Hill district. Of this amount the Western Utah Copper Co. shipped 112 cars, the Pole Star 3 cars, the Copperopolis 1 car, and the Garrison Monster 1 car. During the month of October 91 cars were shipped, 85 cars coming from the Western Utah Copper Co., 2 cars from the West Mountains Development Co., 1 car from the Monacca Mines Co., 1 car from the Seminole, 1 car from the Garrison Monster, and 1 car from the Pole Star. The reduced output for the month of October was due to the smelter embargo. At the Pole Star some high-grade copper ore has been uncovered in driving the No. 1 tunnel. The same company will sink its 150-ft. shaft to the 500-ft. level. At the 150-ft. level drifts are being extended both north and west. A strike of heavy sulphide copper ore has been made in the Western Utah extension. The Seminole company has recently made some shipments of ore containing rare metals.

The Emma Consolidated at Alta is shipping from 60 to 70 tons per day. October shipments averaged 65 tons per day, the ore netting \$30 per ton after deducting smelter and railroad charges. The earnings for the month were approximately \$60,000. Since shipments started in April about 8000 tons has been sent to the smelter. Snowfall at Alta is unusually light, being only a few inches against the normal amount of two to three feet. The Michigan Utah at Alta is shipping about 60 tons of ore daily. Shipments during October totalled 49 cars. Transportation difficulties in Little Cottonwood canyon prevented the moving of a larger tonnage. It is reported that the roads are in bad shape. The Michigan Utah has been a heavy shipper during the past month, 600 tons having been sent to the smelter in one week. The drift south on the Lavinia has been driven 100 ft. in ore and there is 5 ft. of ore in the breast extending both above and below the tunnel-level. The tramway has been put in condition for winter work. The Columbus-Rexall is shipping 35 tons of ore per day. The ore is being hauled to the sampler by team. Since the new orebody was cut three months ago there has been mined and shipped about 1900 tons of ore netting approximately \$30,000. The adit of the Alta Tunnel & Transportation Co. in Silver Fork is now in 3000 ft. and work will be carried on throughout the winter. The Prince of Wales and Woodlawn properties in Honeycomb gulch are also laying in supplies so that work can be carried on through the winter. The Alta Consolidated is now hauling ore by team from Alta to the valley smelters. An ore-bin and chutes are about completed and a connection is to be made with the Michigan Utah tramway, avoiding the wagon haul to Tanner's Flat. The Alta railroad has been completed and additional equipment, including a Shay locomotive and 50 six-ton cars, has been ordered. The railroad is narrow-gauge with exceedingly heavy grades and sharp curves. The 30-ton cars originally provided were not found to be serviceable. Alta operators expect that this road will offer a substantial

solution to the difficult ore-hauling problems from Little Cottonwood canyon.

The Tintic Standard at Eureka has about 80 men at work. Shipments average about \$90 per ton running 70 oz. silver,  $2\frac{1}{2}\%$  copper, and 10% lead, with \$6 in gold. Selected specimens show as much as 400 oz. silver and \$35 in gold. Fifteen teams are hauling ore from the mine. Surveys have been made for a spur-track from the Denver & Rio Grande railroad. The Iron Blossom is sinking its No. 1 shaft below the 1900-ft. level. The only work below this level has been done with a diamond-drill. The drilling has demonstrated more favorable limestones than shown on the 1900. A number of lessees are working the older parts of the mine. On the 900-ft. level of the Eureka Mines Co.'s property the main drift has entered the east and west fissures where good ore has been found. Some additional work will be needed to determine the extent of this discovery, but the present indications are promising. Heavier shipments are now possible from the Gemini and the Ridge & Valley mines, railroad-cars being more plentiful. A large amount of ore is now available at the Gemini, and while it may be some time before the mine is permitted to move its regular output of about 500 tons per week, some of the accumulated ore can be shipped. Production from the Chief Consolidated for the quarter ended September 30 was derived from the 700, 800, 1600, and 1800-ft. levels. Shipments for the quarter were considerably curtailed on account of the smelter embargo. Men formerly employed on the ore have been put on the development work. Dump-stations are being made at the 600, 1200, and 1800-ft. levels. The Chief is rapidly completing the installation of the new electrically operated pumping-plant. Concrete reservoirs of 60,000 gal. capacity each have been constructed on the 600, 1200, and 1800-ft. levels, where the pumping units are to be placed. The

water-level is at the 1800-ft. level. Important orebodies are known to extend below that point. The work which has been done indicates that no great difficulty will be experienced in handling the water. The ore from below the water-level is a sulphide product and different from anything that is found in other parts of the mine. Dur-

ENTRANCE OF THE ALTA ADIT, BIG COTTONWOOD DISTRICT

PART OF GOLD HILL, SHOWING THE OLD WOODMAN MILL AND REMAINS OF AN OLD SMELTER

ing October 2900 ft. of development was completed. A new unit to the compressor plant will be completed in a short time. The unit comprises a direct motor-driven compressor having a capacity of 2500 cu. ft. of free air per min. At the present time the Chief is using a Nordberg compressor of 1500 cu. ft. capacity and a Sullivan compressor of 750 cu. ft. capacity. The 400-ft. shaft on the Plutus, recently taken over by the Chief, has been repaired and hoisting machinery has been installed. Development work is planned on the 400-ft. level.

The Utah Copper Co. is installing an ore-crushing plant that will cost \$250,000. The crusher, which will be the largest in the United States, is to be installed at the Arthur mill, and is of the gyratory type. An electrically operated Wood rotary car-dump will be used for unloading the railway-cars. The 38th quarterly report, covering the period ended September 30, has just been issued. The net profit for the quarter was \$2,834,225 as compared with \$10,563,541 for the second quarter. This large decrease in earnings is explained by the fact that the earnings for the third quarter were computed on the basis of 14.030c. for copper as compared with 27.977c. the previous quarter. During the third quarter there was removed a total of 1,230,677 cu. yd. of cap as compared with 1,129,198 cu. yd. for the second quarter. The Bingham and Garfield hauled an average of 32,019 tons of ore per day. During the quarter a total of 3,439,400 tons of ore was treated, being 141,000 tons more than for the preceding quarter. The average grade of the ore was 1.3059% copper as compared with 1.3881% copper for the second quarter. The average cost per pound of net copper recovered in the concentrate was 10.860c., which is an increase of 1.396c. as compared with the second quarter of 1917, when the average cost was 9.464c. This high cost was due partly to the heavy charge made against operations for increased State and Federal taxes, partly to the increase in wages, and partly to the low grade of the ore. During the month of June mining was resumed at the Utah Apex on a small scale and the working force gradually increased so that by the end of July operations were again on a normal basis. The company benefited by the high price of lead and silver during the quarter, but a sharp decline in the price of lead during the last month makes the outlook much less promising. The Utah Metal & Tunnel Co. has paid dividends to the amount of \$548,140 for the year 1917. Owing to the recent slump in the lead market it has been necessary to reduce the working force.

The Spiro tunnel of the Silver King Consolidated Mining Co. at Park City is now in about 4600 ft. and is being driven at the rate of 10 ft. per day. The smelter embargoes have reduced the company's production from 50 tons to 40 tons per day. The mill is shipping a car of high-grade concentrate each week. A large amount of mill-ore is being taken from dumps accumulated in past years.

Considerable activity is reported in the Gold Strike district. Work is being done by the Baker, Gold Strike, Search Light, Gold Valley Gold, Bonanza, and others.

The Baker is sinking a vertical shaft and is down 170 feet.

**OZOKERITE.** The American Chemical & Ozokerite Co. recently shipped ozokerite wax to the value of \$12,000. The product sells for 75c. per pound at New York. The company is putting in a new crushing and milling plant, which will double the present output.

**POTASH.** The plant of the Minerals Products Co., at Alunite, near Marysville, was destroyed by fire recently, entailing a loss of about \$250,000. The fire was accidental, being caused by an explosion in the coal-dryer. The plant was new, having been in operation only about a year. This is the second fire within that time. About 500 men were employed and the plant was one of the largest of its kind in the United States, and has been producing about six carloads of high-grade potash each week. Re-building has started and it is announced that the plant will be re-constructed with double its former capacity.

**GROWTH** of chemical industry in the United States since 1914 has been phenomenal. The country now manufactures practically everything required in matters chemical. The increase in capital invested in the chemical industries was, in 1915, \$65,565,000; in 1916, \$99,244,000; and up to September 1917, \$65,861,000 over the preceding year. New chemical industries are being started at an unprecedented rate, owing to war needs, under the energy of American chemists and physicists. Sulphuric acid, the chemical barometer, has doubled in production. In 1916, 6,250,000 tons of 50° Baumé acid was produced. The estimate for 1917 is much greater, and the production for 1918 will again greatly increase.

THE first discovery of gold in Montana, according to the U. S. Geological Survey, is accredited to a half-breed Indian, who found 'colors' in gravels near the mouth of Gold creek, a small stream that rises in the north-east corner of the Philipsburg quadrangle, in 1852, and the first workable placers discovered in Montana were found on this creek in 1862. A small quantity of gold was taken out by means of sluice-boxes near the present site of Pioneer. The deposit afterward exploited by the Hope mine was discovered in December 1864, and in 1865 Philipsburg was founded just south of the mine. Since that time the Philipsburg district has produced about \$50,000,000 in gold and silver.

**BY-PRODUCT** coking plants doubled in capacity in the last three years, yet in 1918 the United States will make half her coke in beehive ovens. Light oil, which contains the benzene and toluene needed for explosives, jumped from 7,500,000 gal. in 1914 to 60,000,000 in 1917, and is again being largely increased. Production of ammonia has increased 100% in three years, and the visible supply is insufficient to meet the demands. Gasoline production has increased from 35,000,000 to 70,000,000 bbl. per annum since 1914.

## A Flotation Patent

Herewith we give the text of Patent No. 1,246,665, dated November 13, 1917, granted to Walter A. Scott, of Chicago.

My invention is an improved flotation process. In the flotation process as previously practised, as is well known, certain reagents or modifying agents generally termed oils, although many of such substances are not oils, are added to a freely flowing ore pulp whereupon the introduction of air or some other gas into the pulp gives rise to the formation of bubbles which collect the desired mineral, generally metalliferous sulfids, and reject the gangue.

The modifying agents used for this purpose comprise a great variety of oils, animal, vegetable and mineral oils, coal and wood tar and derivatives thereof, various alcohols, hydroxyl compounds and other substances, all of which I refer to herein, for the sake of brevity, as oils. Air, of course, is the most available gas and the one generally used, but in referring to air herein I include all gases which have a similar action.

Heretofore the air necessary in the operation of the process has been introduced into the ore pulp either by mechanical agitation which has the effect of beating in the air from the atmosphere, or by introducing air into the pulp through a porous medium forming part of the vessel in which the pulp is contained. Detailed explanation of the flotation process as heretofore practised is unnecessary in view of the fact that the process is widely known and described in many patents and publications, among them Patent No. 1,022,085 granted to J. M. Hyde April 2, 1912, Patent No. 1,104,755 granted to J. M. Callow July 29, 1914, and Patent No. 1,125,897 granted to J. M. Callow January 19, 1915.

In the operation described in the Hyde patent above referred to the air is beaten into the pulp by mechanical agitation, and in the operation described in the Callow patents above referred to the air is introduced under slight pressure through a porous medium, the pressure being just sufficient to over-balance the hydrostatic head of the pulp and to overcome the resistance of the porous medium. In the mechanical agitation method of introducing air the mechanical agitation imparted to the pulp for that purpose is sufficient to thoroughly disseminate the oil through the pulp, such distribution of the oil being necessary in order that it may accomplish its function. In the method of introducing air through a porous medium it is necessary that independent means for mixing the oil be adopted and such independent means have heretofore taken the form of mechanical agitation sufficient to disseminate the oil, but not for the purpose of introducing air into the pulp and not having that effect to any appreciable or useful extent, reliance being placed for the introduction of air upon forcing it

through the porous medium after the mechanical mixing of the oil with the pulp.

I have ascertained that the oil performs its principal, if not its only, function in the film surrounding the air bubbles and my invention consists in introducing the oil in such manner that it is supplied directly to the bubble films without the necessity of disseminating the oil through the entire body of ore pulp. My invention consists in using a volatile oil, impregnating the air with the gasified volatile oil, and introducing the gaseous mixture of air and oil into the pulp whereupon sufficient of the oil collects in the bubble films to effect the desired

function. When operating according to my invention the necessity of mechanical agitation for the purpose of mixing the oil with the entire body of ore pulp is dispensed with and the amount of oil necessary for the purpose is greatly diminished in quantity by reason of the fact that the oil is applied directly to the bubble films where it is needed, without the necessity of distributing the oil throughout the body of the ore pulp in order to accomplish that purpose.

The drawing forming part of this application is a diagrammatic representation of means of applying my invention, and is a cross-sectional view of an apparatus designed for applying my invention by introducing the gaseous mixture of air and oil through a porous medium into the pulp.

In the figure A represents a containing vessel for the pulp, the same being provided with launders B into which the mineral bearing bubbles overflow. C represents the pulp contained in the vessel, A and D the column of mineral bearing bubbles represented as filling the upper part of the vessel A and overflowing into the launders B. E is a porous medium spaced some distance above the bottom of the vessel A, this porous medium being composed of several layers of canvas or

other fabric or of some other porous medium such as unglazed porcelain, or other substance. Between the porous medium E and the bottom of the vessel A there is an air space F into which air under pressure is introduced through the pipe G. The air pressure in the space F is sufficient to support the head of pulp in the vessel A and to force the air through the pores of the medium E. H is a vessel containing some volatile oil and I represents a steam coil for heating the same, if necessary.

In operation the air supplied through the inlet pipe G becomes impregnated with the gasified modifying agent which vaporizes from the vessel H and the mixture of air and gasified oil penetrates the permeable medium E and rises as bubbles through the pulp C. The effect of this is to form the bubble column D above the pulp, the bubbles forming the bubble column having collected the metalliferous mineral during their passage through the pulp and subsequently being overflowed with the mineral into the launders B. The bubbles collected in the launders B may be broken down by any suitable means, as by a spray of water and the precipitated mineral collected as concentrate. The concentrate so collected may, as customary, be retreated to further purify it, if necessary.

While I have shown certain specific means for effecting the mixture of ore with gasified oil, it will be obvious that my invention is not restricted to the specific means shown, nor is my invention restricted to the use of any particular volatile oil. A variety of suitable substances are volatile and many others such as coal tar, and the coal tar products contain volatile constituents.

What I claim is:

1. An ore concentration process comprising the operations of vaporizing a modifying agent and forming a mixture thereof with air, introducing said mixture through a fine texture porous medium into an ore pulp and forming bubbles to which certain mineral particles in the ore adhere as said bubbles rise through the pulp, causing said mineral-bearing bubbles to form a column of bubbles above the pulp and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

2. An ore concentration process comprising the operations of vaporizing a modifying agent and forming a mixture thereof with air free from modifying agent in the liquid state, introducing said mixture into an ore pulp in the form of bubbles to which certain mineral particles in the ore adhere as said bubbles rise through the pulp, causing said mineral-bearing bubbles to form a column of bubbles above the pulp and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

3. An ore concentration process comprising the operations of vaporizing a modifying agent and forming a mixture thereof with air free from modifying agent in the liquid state, introducing said mixture through a porous medium into an ore pulp and forming bubbles to which certain mineral particles in the ore adhere as said

bubbles rise through the pulp, causing said mineral-bearing bubbles to form a column of bubbles above the pulp and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

4. An ore concentration process comprising the operations of vaporizing a modifying agent and forming a liquid free mixture thereof with air, introducing said mixture into an ore pulp under pressure not substantially greater than that necessary to sustain the hydrostatic head of the pulp, thus forming bubbles which are impelled upwardly through the pulp by their buoyancy only and to which certain mineral particles in the ore adhere, causing said mineral-bearing bubbles to form a column of bubbles above the pulp, and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

5. An ore concentration process comprising the operations of vaporizing a modifying agent and forming a mixture thereof with air, introducing said mixture through a fine texture porous medium into an ore pulp under pressure not substantially greater than that necessary to sustain the hydrostatic head of the pulp and to overcome the resistance of the porous medium to the passage of the gaseous mixture, thus forming bubbles which are impelled upwardly through the pulp by their buoyancy only and to which certain mineral particles in the ore adhere, causing said mineral-bearing bubbles to form a column of bubbles above the pulp, and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

6. An ore concentration process comprising the operations of exposing a body of liquid modifying agent having a relatively large exposed surface to a current of air thereby vaporizing part of said agent, introducing the mixture of air and vaporized modifying agent so formed free from any of such agent in liquid form into an ore pulp in the form of bubbles to which certain mineral particles in the ore adhere as said bubbles rise through the pulp, causing said mineral-bearing bubbles to form a column of bubbles above the pulp and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

7. An ore concentration process comprising the operations of exposing a relatively large surface of a liquid modifying agent containing a volatile constituent to a current of air thereby vaporizing part of said agent, introducing the mixture of air and vaporized modifying agent so formed free from any of such agent in liquid form into an ore pulp in the form of bubbles to which certain mineral particles in the ore adhere as said bubbles rise through the pulp, causing said mineral-bearing bubbles to form a column of bubbles above the pulp and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

8. An ore concentration process comprising the operations of exposing a relatively large surface of heated liquid modifying agent to a current of air thereby vapor-

izing part of said agent, introducing the mixture of air and vaporized modifying agent so formed free from any of such agent in liquid form into an ore pulp in the form of bubbles to which certain mineral particles in the ore adhere as said bubbles rise through the pulp, causing said mineral-bearing bubbles to form a column of bubbles above the pulp and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

9. An ore concentration process comprising the operations of exposing a body of heated liquid modifying agent having a relatively large exposed surface containing a volatile constituent to a current of air thereby vaporizing part of said agent, introducing the mixture of air and vaporized modifying agent so formed free from any of such agent in liquid form into an ore pulp in the form of bubbles to which certain mineral particles in the ore adhere as said bubbles rise through the pulp, causing said mineral-bearing bubbles to form a column of bubbles above the pulp and separating the mineral carried by the bubbles in the upper part of the bubble column from the remainder of the ore.

## Sponge Iron in California

Many attempts have been made in recent years to manufacture sponge iron from ores and from the calcine left after burning pyrite for the manufacture of sulphuric acid. Rather elaborate experiments of this kind were made a few years ago by Frederick P. Laist, at Anaconda, his effort being to obtain a sponge iron suitable for use in precipitating copper from sulphate solutions. It did not, however, prove economical. In Spain similar attempts were made prior to the War, using large rotary furnaces fired with producer-gas. The results were so successful as to attract wide attention, and a company was formed in England under the leadership of Sir William McKenzie to exploit the process. The enterprise is reported to have advanced to the point of erecting experimental works at Birmingham. The great attraction that the manufacture of sponge iron holds for the world is the possibility of using liquid or gaseous fuel, apart from the merits of the product itself, which are very nearly those of wrought-iron, and to some extent those of mild steel. For the West it is a matter of great importance. California, for example, possesses large deposits of iron ore and an abundance of asphaltic oil, but no coal, nor is there cheap blast-furnace coke available from any source. Among the many that have experimented on the matter one of the latest is Herbert Lang, who has erected a small plant at Emeryville, near Oakland, Cal., where he has produced a good quality of sponge iron direct from Pit river magnetite, an ore containing 65% metallic iron. The ore is ground to 16 mesh, and is mixed into a paste with Kern river, 13° B., crude asphaltic base oil. The paste is molded into cylinders 8 in. diam. by 15 in. long. No flux was used in the earlier experiments, but the necessity for doing so is now seen, although the insoluble constituent in the Pit river

magnetite is less than 2%. The cylinders are charged into the hearth of a reverberatory furnace and heated to the welding temperature of iron, that is, about 2000°F. The furnace is fired for eight hours with crude oil, maintaining a reducing atmosphere. The product holds together as separate masses, each representing an original cylindrical mass or briquette. These are removed from the furnace and squeezed in the same manner as blooms in the making of wrought-iron.

## Phosphate Rock

Prior to 1914 about 40% of the phosphate rock produced in this country was exported. Most of the exported material is high-grade rock from Florida. Some think it unwise to allow more than 1,000,000 tons of high-grade phosphate to go from this country, as it did before the War, to enrich the soils of Europe. They believe American deposits of high-grade rock are exhaustible, and when the rock is sent abroad the phosphorus, on which the agricultural prosperity of a country partly depends, is irretrievably lost to us. When we use phosphate rock on our own soils the phosphorus in it can be removed in crops and in large part returned to the soil again in the by-products of the farm—green manure, farm manure, bone-meal, and tankage. Not only once, but over and over again, the phosphorus may play its part in producing crops. The economic loss in allowing the phosphate to leave the country is therefore manifold. The phosphate rock that is exported to gain a few million dollars annually would, if applied to our land, play its part in producing hundreds of millions of dollars in cotton and corn. Another and broader view, however, may be taken of the situation. The world's annual production of phosphate rock is about 6,000,000 tons. The phosphate reserves in the United States amount to about 6,000,000,000 tons. At the rate of mining during the last few years the high-grade deposits of the Eastern States cannot last long. In the Western States, however, there is 5,750,000,000 tons of high-grade material in the areas that have been examined and classified, no account being taken of rock carrying less than 30% tricalcium phosphate. These figures make the situation seem less discouraging. At the present rate of consumption in the entire world, the deposits in the western United States would supply the demand for about 900 years. The use of phosphate for agricultural and other purposes is bound to increase, but it will be a long time before it reaches 10,000,000 tons per year. Even if the world should demand a quantity so large as that, the Western States could supply it for more than 500 years. How long phosphate could be mined and shipped at prices that could be paid abroad is another question.—U. S. Geological Survey.

BEFORE the War 40,000 tons of barite was imported from Germany for the manufacture of lithopone. Now five companies are producing this article from deposits in Tennessee, Kentucky, Virginia, and Missouri.

## Searles Lake Potash

At the recent annual meeting, in London, of the Consolidated Gold Fields of South Africa, the chairman, Lord Harris, had this to say concerning the Californian potash enterprise in which his company is heavily interested:

"Now, as regards American Trona Corporation, you will, I feel sure, be anxious to hear the latest news of that venture. It has taken a longer time than we originally anticipated to reach the producing stage. We were unlucky in our first reduction plant, which failed to come up to expectations. I am happy to say that the second effort has been successful—I think I may say very successful. The producing stage was reached at the end of October last year, since when the plant at Searles Lake has been in continuous operation. Owing to the fact that the mixed salts produced are required in ever-increasing quantities for fertilizing purposes, and command a satisfactory price, it was decided not to press on with the completion of the refinery at San Pedro, which, consequently, will not be in operation till early in the coming year, by which time the second unit of plant at Searles Lake should be completed. All chemical difficulties have been overcome and the Grimwood process has proved its ability to solve the problem of separating all the constituent salts of the brine. Up to now, however, we have suffered considerable disappointment as regards the output of mixed salts, on which at present the Trona Corporation depends for the greater part of its income. For the seven months ended August 31, the output of these salts has amounted to 8348 tons, or an average of a little over 34 tons per day, as against the 70 tons which we were informed might be anticipated. This reduced output is in some measure due to the abnormal heat obtaining in the desert, where the bulk of the reduction plant is erected, from May to September inclusive, which retards the crystallization of the salts. With the return of cooler weather we may expect a considerably increased production, and that, after certain supplementary plant now on order has been installed, the daily output of the first unit will, it is estimated, amount to at least 70 tons. The most recent telegram as regards production shows that in October we had got up to 43½ tons, and had also sold 55 tons of high-grade potash for the chemical trade. You will be interested to know that the profits for the month of October amounted to \$133,000; that was on an output of about a quarter of what we anticipate it will be when the second unit at Searles Lake and the refinery at San Pedro are complete, which we hope will be the case next April.

"The difficulty of obtaining and forwarding structural steel has greatly delayed the erection of the second unit, and has involved a serious increase of capital expenditure, which, however, is compensated for by the abnormal price of potash now ruling and likely to rule for some time to come. The near approaching completion of the second unit and of the refinery will result not

only in a largely increased production of the mixed salts required for fertilizing purposes, but will also enable the corporation to produce a considerable amount of practically pure potash required by the chemical trade, as well as to segregate and market the borax, which is the most important of the corporation's by-products. The title question is still undecided. The hearing of the corporation's application for patent took place at Washington at the end of September, and we are informed that our representatives await the decision of the Commissioners with complete confidence. The corporation has done good work in helping to allay the potash famine in the United States which the War has caused, and we feel justified in believing that the Government of that allied country will not fail to show some recognition of this fact in its treatment of the corporation. Of course, we have to anticipate a falling off in the price of potash after the War, when its exportation from other parts of the world re-commences, but that will be compensated for by the production of by-products, which we believe has been satisfactorily proved at the San Pedro refinery.

## Compensation Law in California

The legislature of 1917 amended the present State compensation laws in a number of particulars and the changes will become effective January 1, 1918. One of the important changes is that which requires every employer, except the State and all political sub-divisions or institutions thereof, to secure the payment of compensation in one of the following ways:

1. By insuring and keeping insured in an insurance company duly authorized to write compensation insurance in this State.

2. By securing from the Commission a certificate of consent to self-ensure, which may be given when satisfactory proof of the employer's ability to carry his own insurance is furnished.

The Commission will require such employer to deposit with the State Treasurer a surety bond or securities approved by the Commission, in an amount to be determined by the Commission. If an employer fails to secure the payment of compensation, he is subjected to an added liability, as his injured employee can not only claim compensation but may also bring an action at law for damages and shall be entitled in such action to the right to attach the property of the employer, to secure the payment of any judgment that may be obtained. In any such action the employer is denied the defences of tributary negligence, assumption of risk and negligence of fellow servant, and the negligence of the employer is presumed.

Those employers who wish to obtain a certificate of consent to carry their own insurance, or who may desire further information on any question relating to the compensation laws, should make application to the Industrial Accident Commission, 525 Market St., San Francisco.

# Mining Companies and Excess Tax

The American Mining Congress, responding to invitation from the Commissioner of Internal Revenue, outlines a few respects in which the excess-profits tax law will work injustice and inequality of taxation to mining companies, taxing the conservative companies with small stock-issues at a relatively much larger amount than those with inflated capital.

The memorandum says:

A mine or an oil-well is a very different property from any other. Owners of mines and wells must seek, find, and extract their product from beneath the earth. This process generally requires an immense expenditure for development work, which expenditure is not carried to capital account. In the case of the great majority of smaller enterprises each mine is owned by a separate company, which cannot add to the purchase price of its properties expenditures for development work and losses sustained in proving other properties to be valueless, an advantage possessed by the large corporations. When the ore is mined out the capital is absolutely gone.

Now the War Revenue Act takes no account of the peculiar nature of mines and wells, giving them no benefit whatever from the discovery of new orebodies. So far as mines are concerned, the definition of 'invested capital' in section 207 of the Act sets a premium on all of the discreditable devices of the past 20 years intended to work up and inflate book-values as a basis for the issue of watered stocks.

Any technical limitation that prevents a company's fixing as its invested capital the real value of its property works an injustice to that company; and any technical provision that enables one company to fix its invested capital, and hence its deduction, at a larger amount than another company with exactly the same property and exactly the same income, works a great injustice to the latter.

We contend that section 207, unless it be construed as suggested in III below, will be particularly objectionable from either one of these standpoints, and that it will be particularly objectionable from the standpoint of mining companies of small capitalization. We therefore make three suggestions under the following heads:

## I

The words "but in no case to exceed the par value of the original stock or shares specifically issued therefor" should be stricken out of section 207 (a) sub-division 2.

If it remains in the Act it will bring about exactly the opposite result from that intended by the framers of the law. Presumably their object was to prevent companies with inflated capital and watered stock, over-capitalized for stock-jobbing purposes, from taking advantage of their inflated capital to reduce their taxes.

Suppose a company on December 31, 1913, issues only

\$100,000 capital stock specifically for assets worth \$1,000,000, setting up no surplus whatever. Under section 207, its 'invested capital' is only \$100,000; whereas another company with the same assets and the same capital stock, organized on January 2, 1914, just two days later, will be allowed as 'invested capital' \$1,000,000. So that the latter company will be entitled to a deduction of \$93,000 as against \$12,000 for the first company, unfortunately acquiring its assets in the year 1913.

Take the provision that invested capital as to property acquired prior to 1914 shall not exceed the par value of the stock issued therefor. Suppose two companies are incorporated in 1910 each with assets worth \$1,000,000. One issues only \$100,000 capital stock, while the other issues \$10,000,000. And suppose that the property of each on January 1, 1914, is worth \$10,000,000, and suppose the income of each for 1917 is \$500,000. According to the strict provisions of section 207 (a) sub-division (2) the first company will probably be allowed only \$100,000 as its capital invested, while the second will probably be allowed \$10,000,000. If the percentage of deduction is 9%, the first company will be allowed to deduct from its \$500,000 only 9% of \$100,000 in addition to the \$3000 fixed deduction, or \$12,000 in all; while the second company will be allowed to deduct \$903,000. In other words, the first company will have to pay an excess-profits tax on \$488,000 income, while the second will pay no excess-profits tax whatever.

The injustice is particularly great to conservative mining companies, for many mining companies are largely over-capitalized, capitalized largely on their trust in the future. We simply ask that these companies should be compelled to pay exactly the same tax as the conservative ones owning properties of the same value and receiving the same income.

Par value of capital stock is in no sense a criterion of real value. In fact, the question may well be raised whether this provision which makes your excess-profits tax depend on the par value of your capital stock is not so artificial and unjust as to be unconstitutional.

## II

The words "at the time of such payment" should be omitted from section 207 (a) Sub. 2 and (b) Sub. 2.

The attempt to limit 'invested capital' to the value of property at the time of its acquisition is peculiarly unjust in the case of the smaller mining company. This provision clearly discriminates against the mining company which only after the expenditure of large amounts of money and time finally succeeds in putting itself on a paying basis, which increases the values of its properties not by sitting and watching them grow, but by the expenditure of large amounts of money and labor and energy. As it has by these means increased the value of

its properties, it should in all justice and fairness be permitted to use these values in determining its 'invested capital.'

Suppose a manufacturing plant worth \$1,000,000 to be acquired for \$1,000,000 stock in 1910, that it was worth \$1,000,000 on January 1, 1914, but that by reason of wear and tear, falling off in business or other causes, it is today worth only \$250,000. Under section 207 the 'invested capital' of this company is today \$1,000,000, whereas its real assets are worth \$250,000.

It is difficult enough to determine the value of a mining property as of today, but this provision makes it necessary today to attempt in some way to determine the value of all sorts of property as of four years ago, a task that will be productive of endless disputes and probably much litigation.

Finally, the Government itself, in its capital-stock tax-law, yearly makes a rough attempt to value the assets of a corporation by fixing the value of its capital stock. Surely it is not unreasonable to ask that the same principle be adopted when there is an effort to fix the ratio of income to invested capital or the amount of invested capital to be used in determining the amount to be deducted from income before applying the excess-profits tax.

### III

The words "earned surplus" in section 297, Sub. 3, of the Act should be construed to include the values of ores and mineral deposits discovered, located, and developed in any mine since the organization of the company, and should be considered as 'invested capital' within the Act, to the extent that such developments add to the net values of the company in excess of its capital stock. Such values are 'earned' and constitute surplus.

Life of all mineral properties is limited, and in most, great fluctuation and differences in the value of the ore and mineral deposits occur over limited periods, due to exhaustion on the one hand of its ore by the ordinary process of mining, and the discovery of ore due to the expenditure of money and time in development work, on the other. For this reason the values of the mining properties are subject to constant change.

This is not generally so, however, in the case of manufacturing and mercantile corporations.

A mining corporation, therefore, differs from a manufacturing or mercantile business in that its source of supply (its ores) is a question of uncertainty; and the values of its assets dependent on the discovery of ore or mineral deposits through the expenditures of moneys and work, are subject to increase or decrease within limited periods of time.

The discovery of ore or mineral is not, however, in any sense to be considered unearned increment. Mining values discovered and so developed as to be readily valued within reasonable limits are values earned and produced as the direct results of (a) mining and engineering skill, (b) the expenditures of moneys and time in opening up the mine, and (c) the employment of labor. The fact that there is a hazard or chance incident

to every such discovery does not make the discovery, when successful, any the less earned as the reward of and as the result of industry. There would be no discovery if there was no work done.

It would, therefore, follow that if through the discovery of mineral in place, such a substantial increase in the values of the company's property would occur that there would be a surplus of value over "the actual cash value of tangible property paid in other than cash, at the time of such payment" (section 207), that such value should be considered first as 'earned' for the reasons set forth above, and second, as 'surplus' or increase over the original capital invested, and should become within the definition of section 207 of the Act 'invested capital' and 'earned surplus.'

Unless a broad construction be given to the words "earned surplus" so as to include ore discoveries, as above, many mining companies will pay from 50% to 60% as a war tax, while companies in other lines will pay but 25% to 40% on the same value.

If, however, the value of this ore, so discovered and developed as the result of underground work, be considered 'invested capital' under the heading 'earned surplus,' a more uniform rate of taxation would be placed on the various mining industries, and the basis of taxation would become scientifically fixed at the present value of the mining property and not on a value fixed some time in the past nor based upon a 'value created' by the whim of the original incorporator of the company.

For the reasons given, it is submitted that ore so found and valued be considered as 'earned surplus' and 'invested capital.'

If the construction of the law above suggested be adopted, then it will not be necessary to amend the law as indicated in I and II above. It is therefore highly desirable for all interests that such a construction be adopted.

PRIOR to the War China had contributed largely to the supply of antimony, and the Chinese, considering the exceptional demand that would be created for this mineral for use in the manufacture of ammunition, proceeded to further development and production. For a time it was in prime demand, and the Chinese were able to dispose of their output at satisfactory profits. Large stocks were accumulated by speculators, but they failed to take into consideration the impetus that would be given to the antimony industry in other parts of the world through an increased demand. When large shipments from Bolivia and Spain began to arrive in the markets, prices began to fall, and continued steadily to decline during the year 1916. The result was that the speculators suffered heavy losses, and many Chinese mines and works had to discontinue operation.

NEW ZEALAND has offered a bonus of 8s. per pound for the first 100,000 lb. of retorted quicksilver that the mines in New Zealand produce under certain restrictions and conditions. There are said to be several rich deposits of quicksilver in the Dominion.

# REVIEW OF MINING

## ANCHORAGE, ALASKA

### DEVELOPMENT AT CACHE CREEK.

The Cache Creek Dredging Co., of which Bulkeley Wells is president, operated from May to September most satisfactorily. The season was cut short by floods about September 8. This marked the highest water in the district for 18 years. Thirty new buckets were taken up the Susitna river this year. The Government, through the Alaska Engineering Commission, offered great assistance to these placer operators by allowing them use of boats and crews to pull their freight up the river to McDougall. This company leases about 12 miles of the lower stretches of Cache creek from the Cache Creek Mining

Co. This tract averages 600 ft. in width. It has a depth of about 7 ft. of gravel and a grade of  $1\frac{1}{2}\%$ . The 7-cu. ft. steam-driven dredge, which was installed at the mouth of Cache creek, has worked its way almost out of the large boulders that were so troublesome at first. At the time of starting work last spring the ground was found to be frozen almost three feet deep, which was unusual, as ordinarily it freezes only about six to eight inches. The altitude of these properties is about 2000 ft. and if the snow falls early in the fall before the ground freezes, and covers the ground like a blanket, the gravel can then be mined in the following spring without thawing by steam-points. During the season of 1917 it was practically impossible to secure any quantity of good

U. S. GEOLOGICAL SURVEY

BULLETIN 607 PLATE I

PART OF ALASKA, SHOWING POSITION OF CACHE CREEK

labor, although the men were paid \$4 per day and board, amounting to \$5 for common labor. The abundance of work all through Alaska and the States, and particularly the excessive wages paid in the base-metal mines, have made it difficult to secure men for work in isolated camps like the Cache Creek district. The men were restless, quitting without notice, and it required two weeks to make the trip to Anchorage to secure substitutes for those that had gone. The Cache Creek Dredging Co. is also operating properties 60 miles overland from McDougall. Cache creek is a tributary of the Kahlitna river, which flows into the Yentna and thence into the Susitna; the Susitna flowing into Cook's Inlet. This district is about 40 miles directly south from Mt. McKinley. The Government is building a wagon-road from Talkeetna, a station on the new railroad, into the district, and it is hoped that it will also erect a telephone line, which will mean a great deal to the operators in securing men and filling emergencies. The construction of this new wagon-road should effect a great saving for all the mines of the Cache Creek district, as at present supplies have to be transferred to small vessels, thence into boats, and then landed and hauled into the mines.

The Cache Creek plans to electrify the dredge next year, good for six months of the year, installing a hydro-electric plant on Cache creek. Up to this time, the dredge has been operated by steam generated by coal, which is mined from a five-foot bed of lignite outcropping about a quarter of a mile below the dredge. It has been necessary to employ ten men in the coal mine to get out the necessary supply, and ten men to handle coal between the mine and the dredge. The coal seams have a dip of only 18° and form part of the bedrock, together with sandstone and shale. It is believed by local miners that there is an enrichment of the placer over these coal croppings. Small quantities of scheelite and platinum occur in the gravels of this section and the U. S. Geological Survey is endeavoring to assist in every way in the development of these rare minerals.

T. D. Harris, manager for the Marysville Dredging Co. of California, with which the Cache Creek Dredging Co. is affiliated, has been looking over the plans for electrical installation. One of the great advantages of electrification is that the dredge will draw only three feet with electric motors, whereas with steam-boilers it drew four feet. It will also effect a great saving in labor. The plan is to dam the tailings in the fall of each year, closely behind the dredge and entirely across the river-bottom, so high that the dam will hold the water for a considerable distance ahead of the dredge and thus prevent the gravel from freezing. At the approach of summer the water from the pond will be liberated, and the gravel, having been protected, will require no thawing.

The Thunder Creek Mining Co., on which M. A. Ellis of Seattle is the principal owner, operated two hydraulic plants on Thunder creek and one on Windy creek. Both of these creeks are tributary to Cache creek. The season was good with the exception of the troubled period of the flood early in the fall, when pipe-lines and ditches were washed out. On the upper reaches of Thunder creek, Mr. Ellis has uncovered a large quantity of angular quartz, broken up and mixed with rounded pebbles. This condition on bedrock has been found to exist for 2000 ft. up and down the stream and extends from one rim-rock to the other, 600 ft. across. The owner is puzzled by this peculiar condition, and so far has not been able to find a satisfactory explanation. [It may be glacial drift.—EDITOR.] He is opening up the deposit on one rim by trenching and by an adit. The angular quartz contains particles of free gold and occasionally a piece of quartz will be cracked into two parts held together by free gold. Mr. Ellis hopes to uncover the vein that is the source of this gold and then to sink on it. However, it is possible that the stream has eroded its bed down to a quartz vein that dips at nearly the same angle as the bed of the stream, so that the vein-quartz may

spread over the stream bed. This company employed about 20 men. In 1918 the placer mines of Alaska will have to operate under the 8-hour law, as the quartz mines do now. It is feared that this may cause the abandonment of many small properties, particularly in outlying districts where labor is scarce, at best, and where the margin of profit is already small.

The Annabubb Mining Co., for which Louis Bubb of Susitna, is general manager, operated four hydraulic giants on Dollar creek, which is another tributary of Cache creek. At this property, as on Thunder creek, the lower 40 ft. of a 105-ft. gravel bank was found to be formed principally of angular quartz. The quartz here differs, however, in that it carries little, if any, gold, while the Thunder creek quartz is heavily mineralized. Floods spoiled an extraordinarily good season at this property. The face of the gravel-bank, which is worked for 100 ft. high, caved, covering part of the clean-up and some of the equipment of the company. Next year the owners hope to extend their ditch to Dutch creek, about 8 miles, on the opposite side of the watershed, whence they expect to secure a greater and more constant supply of water. All the mining operations are conducted at the head of Dollar creek, the tailing being dumped into Lower Dollar creek. This is not in accordance with the best practice, as the gravel at the lower end of Dollar creek has not yet been mined and the virgin ground there is being covered with worthless tailing. It is, however, the only feasible way to operate this creek until dredges can be set to work on the lower reaches of Dollar creek. The company employed 12 men during the season. It is probable that the placer miners of this district will ask \$5 per day and board next season. The law provides that no miner shall work more than 8 hours during any 24, even though paid for such additional work.

## MANHATTAN, NEVADA

WHITE CAPS.—UNION AMALGAMATED.—MANHATTAN CON.

The work at White Caps as reported for last week is as follows: On the fourth level raise 407 made 18 ft. for the week, and connection was made with the hanging-wall drift on the 300-ft. level on the shaft vein. This raise has been made for the entire distance between levels in good-grade ore. Stopping operations have commenced from this raise and the stope will be known as 407 stope. From the fifth level the 503 cross-cut has progressed for the week a distance of 23 ft., in shale for 190 ft.; this cross-cut is being extended south and west to reach the shaft orebody. In the mill several minor changes have been made with the object of reducing cost. These improvements produce a more uniform output with an increased tonnage. Conveyor belts from the roaster distribute the roasted product over the mill vats automatically. The mine has added to its accumulation of fuel-oil for the roaster; the local storage tanks have a capacity of 45,000 gal. and these will be filled to capacity in less than ten days. The Butters filter is being put in place and should be in running order in three days.

The week's work at the Union Amalgamated property is as follows: Cross-cut No. 601 advanced five feet in limestone. Drift 609 west in foot-wall advanced 12 ft., starting from 601 cross-cut and following the bedding planes of the formation. This drift is exposing oxidized quartz carrying free gold. The work of enlarging and timbering the Earl shaft for use as an operating shaft is progressing well. The shaft has been enlarged to two-compartment, straightened in the foot-wall, and re-timbered to the 256-ft. level. The new six-drill compressor is on its foundation and the motor is now being set in place for driving it. The building covering the compressor is completed. The company should be operating through the Earl shaft by January 1. Notice has been issued for a special stockholders meeting on December 29 to vote on re-organizing the company into an assessable corporation.

At the White Caps Extension property a sump is being sunk

in the shaft below the 400-ft. level. The timbers for the station at the 400-ft. level are in place and mining will be started east as soon as the sump is completed. The drift east will follow the formation bedding-planes and its objective will undoubtedly be the blue White Caps limestone belt, similar to the limestone that has carried the great orebodies developed by the White Caps company.

At the Manhattan Consolidated a station is being cut on the bottom level, preparatory to sinking a shaft. A sump back in the drift is being cut to hold the water, accumulating during the shaft-sinking. From this sump the station pump will handle the water direct to the surface. A 5 by 8 Gould triplex pump has been purchased by the company, which will handle 100 gal. of water per minute under a 500-ft. head. The miners have been taken out from the development of the east orebody from the 400-ft. level. The present dimensions of the east orebody shows a length of 125 ft.; the last 10 ft. the ore has been narrowing until the face of the drift shows only three feet of ore. A raise from the fourth to the third level on the hanging wall has been started for the purpose of providing better ventilation in the underground workings. The south-west drift from the third level on the free gold orebody has developed one good ore-shoot and three feet of vein material now shown in the face of the drift. The ore south from the shaft is found in pipes or chimneys so that as long as the development follows the ore-zone additional ore may come into the drift at any time.

## TORONTO, ONTARIO

PETERSON LAKE TAILING.—KIRKLAND LAKE MINE.—BOSTON CREEK.

A decision of much interest to mining companies was rendered by Justice Middleton at Toronto on November 29 in an action brought by the Peterson Lake Mining Co. against the Dominion Reduction Co. over the ownership of a large quantity of tailing deposited by the Dominion Reduction Co. and its predecessor, the Nova Scotia Co., in Peterson lake. The tailing, which was formerly regarded as valueless, owing to the high price of silver and the feasibility of its recovery by flotation, may be worth now \$1,000,000. The Peterson Lake Co. owns the bed of the lake, and the Nova Scotia Co., which erected a reduction mill in 1909, deposited its tailing there. When the property of the Nova Scotia passed to the Dominion Reduction Co. in 1912 this practice was continued with the consent of the Peterson Lake management. In 1915 the Dominion Reduction Co., thinking that the tailing might become valuable, obtained from the Peterson Lake permission to remove the deposits if ever they acquired value, provided the Peterson Lake had the right to direct the point of deposit. The claim of the Dominion Reduction to all tailing dumped subject to this agreement after July 2, 1915, was admitted, but the Nova Scotia claimed the ownership of all tailing deposited during the five years prior to that date. The judgment was in favor of the plaintiff company, the judge regarding the case as analogous to that of a land-owner dumping earth from an excavation on a neighbor's lot to fill up a hollow. As the practice of dumping tailing on adjacent properties has been a frequent one, several Cobalt companies, including the Coniagas, Beaver, Hudson Bay, Temiskaming, and McKinley-Darragh are adversely affected by this decision.

The mining companies have done their share in subscribing to the Canadian Victory Loan, the leading contributions from this source being as follows: Nipissing, \$500,000; Mining Corporation of Canada, \$500,000; Hollinger Consolidated, \$500,000; Kerr Lake, \$250,000; Temiskaming, \$200,000; McIntyre, \$100,000; Dome Mines, \$50,000; Coniagas, \$50,000; and McKinley-Darragh, \$50,000.—At the Davidson the mill machinery is on the ground and construction is progressing rapidly.—The Newray, now under option to the Crown Reserve, has a 10-

stamp test mill in operation, and exploration is being systematically undertaken.—The Beaver Consolidated has made its final payment on the purchase of the stock of the Kirkland Lake. On each payment of about \$75,000 a block of stock passed to the purchasers, the first three payments being made in full. The last installment, however, was not fully met, owing to the heavy drains on the resources of the Beaver for development and the new mill so that a small amount of stock remains in outside hands.—The management of the Tough Oakes mine has been assumed by D. H. Angus, formerly of the Right-of-Way at Cobalt. Charles O'Connell, the late manager, has been placed in charge of the Patricia Syndicate at Boston Creek.—The Mondeau claims in the Boston Creek area are under option to the Kerr Lake of Cobalt. Sinking has been commenced and a mining plant will be erected as soon as possible.—The Lake Shore has completed its mill building, and machinery is being erected. Interests associated with the Lake Shore have taken an option on a group of claims in the new Lightning River gold camp near Lake Abitibi.—A winter road is being cut from Kirkland Lake to this field, about 30 miles distant. Many additional claims in Lightning river are being staked and a great rush is anticipated in the spring.

The Miller-Independence mine of Boston Creek is the first gold mine in Ontario to adopt flotation, which for the last two months has been in successful operation at its 35-ton mill. A Blake rock-crusher delivers into a 4 by 5-ft. ball-mill and the latter into a Grotch flotation machine.—The company is treating \$8 ore and obtaining a 94% recovery. The amalgamating plates recover 30%, and the mercury traps a like proportion, the balance being in the form of a flotation concentrate that assays \$200 per ton.

## MAMMOTH, UTAH

BINGHAM DIVIDEND.—NORTH TINTIC MINES.

Just at the time when the Gemini and the Ridge mines were making an effort to clear up the accumulation of ore the smelting company came out with another embargo which limits the shipments from each of the properties to one carload per day. Officers of the mining companies are now trying to line things up for another smelting contract, and it is thought that the new contract, when it becomes effective, will permit of heavier shipments even though it is not as desirable as the one which now exists and which expires this month. Considerable ore is now blocked out in the Gemini, Ridge, and Valley mines.—Last week the Tintic Standard mine shipped eight cars of ore. The ore is being sent to the surface through the new working shaft, new and old workings are now being properly connected, and everything is in shape for economically and rapidly handling the output.—Joseph S. Berry has succeeded John D. Dixon as a director in the Provo Mining Co. Mr. Berry has bought Mr. Dixon's stock of 50,000 shares, and also has acquired other large blocks of stock in the company.—A discovery of scheelite has been made in the raise above the main adit at the Frankie mine of the Woodman Mining Co.—The Bingham Mines Co. has declared a dividend of 50c. per share payable on January 1 to all stockholders of record December 20. Most of the Eagle & Blue Bell stock has now been exchanged for shares in the Bingham Mines. Six carloads, or about 300 tons of ore, left the Scranton mine in the North Tintic district last month. Work is carried on by lessees. R. J. Deighton of Salt Lake is manager.—At a meeting held at Provo on December 8 the stockholders of the Sioux Consolidated Mining Co. voted to sell the property to the Sioux Mines Co., recently organized with 1,000,000 shares of a par value of 10c. per share. Stockholders of the old company will receive one share of Sioux mines stock for two shares of Sioux Con.; 500,000 shares will remain in the treasury and will be used to liquidate the old company's debts, amounting

to about \$20,000, and to push development at the Sioux mine. The directors of the new company are Reed Smoot, C. E. Loose, P. G. Peterson, J. T. Farrer, and Reed L. Anderberg. With the exception of Mr. Peterson, who takes the place of T. R. Cutler, the board is the same as that of the old company.—A body of excellent galena has been opened at the Lehi Tintic and 900 sacks are awaiting shipment. The ore-body has been opened in three different places.—M. K. Nebo has a small force of men at work on the North Tintic Mining & Milling Co. ground, north of the Homansville holdings of the Chief Con., endeavoring to find the continuation of the Chief's manganese vein.—An inclined shaft has been sunk in the North Iron Blossom to a depth of 200 ft., where a small cave was discovered. This cave is well mineralized and assays show the presence of iron, silver, and gold.—The double-compartment shaft being sunk on the Eureka King property is down nearly 300 ft. Salt Lake people are in control of the Eureka King, which is one of the most promising in the North Tintic district.—When the donkey-engine is erected on the 500-ft. level, where a winze is being sunk, another shift will be put to work at the Zuma. This winze is down 35 ft. and has been in excellent ore the entire distance.—Owing to an accident in the shaft the Chief Con. mine lost a couple of shifts work this week. One of the cars became loose while it was being hoisted to the surface and before the engines could bring the cage to a stop the wall plates in the shaft had been torn out for a distance of 50 ft. Cecil Fitch, superintendent, states that some of the development work, which has been going on at the Chief Con. mine, has been discontinued temporarily and that more attention will be given to the mining of the ore during the remainder of the year. He states that this new arrangement does not affect the Plutus, which is being developed through the Chief Con. mine.—Work has been discontinued at the Sioux-Alex adit, controlled by a Bingham corporation. During the past year the prospecting has been done by diamond-drills; seven holes have been put down. The deepest hole was sunk from the 800-ft. level, the drill penetrating the formation for a distance of 1600 ft.—The total shipments from the Tintic district amounts to 190 cars, twenty mines contributed to this amount, together with one car of bullion from the Tintic Milling Co. at Silver City.

### SONORA, MEXICO

#### MOLYBDENUM AND TUNGSTEN ORES.

The St. Saba Mining Co., which is situated some 18 miles south of Douglas, Arizona, has resumed operations after being closed down for several years. Considerable development work has been done on this property and some high-grade lead-silver ore has been shipped in the past.—Several carloads of copper-silver ore are being shipped monthly from the Belen mine, which is situated in the Moctezuma district. S. M. Greenidge is in charge.—A large number of claims containing molybdenum have been denounced recently in the vicinity of Nacozari, Sonora. The molybdenum ore in the form of molybdenite is found in the mountains surrounding Nacozari, most of the mines being within a radius of 20 miles from that place. There is a great deal of disseminated ore in granite formation carrying one or two per cent molybdenum sulphide while numerous quartz stringers are found in the same formation carrying up to 30 or 40% of the sulphide ore. Options upon a number of claims are said to be held by Texas mining men who contemplate erecting a mill to treat the lower-grade ore. In the district of Sahuaripa, 200 miles south of the International line, George Fast and associates are working high-grade molybdenum and tungsten deposits. The ores occur as scheelite and molybdenite and considerable ore of both classes has been shipped during the past year. A carload of molybdenite which has just been shipped is said to have

brought \$38,000.—In the same district are the tungsten and molybdenum mines of J. S. Douglas and associates, from which a large tonnage of high-grade ore has been shipped in the past few years. This ore is packed overland on mule trains for a distance of 150 miles. The Cinco de Mayo group of mines, six miles north of El Tigre, is now being worked by the Mexican government, 50 men being employed. The property formerly belonged to the late Colonel Garcia but was confiscated by the Mexican government several years ago. It has produced several millions of dollars in high-grade silver ore.

The famous Chispas mine, in the Arispe district, is now being worked by its owner; high-grade silver ore is being shipped. This property was taken over and worked by the Mexican government for some time but several months ago was returned to its owner. It is reputed to be the richest silver mine in Sonora and has produced a large tonnage of high-grade ore.

### PLATTEVILLE, WISCONSIN

#### LEAD, ZINC, AND PYRITE SHIPMENTS.—LINDEN DISTRICT.

Complete returns from the Wisconsin zinc-lead field for the month of November show it to be one of the best operating months of the year. While the labor situation had improved for several of the larger operating groups due to the closing down of a number of low-grade producers, weather and road conditions and lowering prices for ore militated against those isolated from immediate railway facilities. Published quotations on zinc ore remained stationary, namely \$62 per ton, base, on premium and high-grade ore with the range down to \$57 per ton on the medium and second grades.—Lead production through November showed decided improvement and the reserve in the field at the end of the month was estimated in excess of 2000 tons. Price offerings remained firm all through the month at \$75 per ton, base, of 80% metal content, but little lead cleared.—Deliveries of ore from mines to refining plants in the field and from mines to smelter direct for the month were made as follows, by districts:

Districts	Zinc lb.	Lead lb.	Pyrites lb.
Benton .....	29,454,000	170,000	750,000
Miffin .....	8,584,000	.....	80,000
Galena .....	4,642,000	66,000	.....
Linden .....	2,724,000	88,000	260,000
Shullsburg .....	1,444,000	90,000	.....
Hazel Green .....	1,300,000	.....	.....
Highland .....	1,080,000	328,000	.....
Platteville .....	986,000	.....	.....
Cuba .....	488,000	.....	4,574,000
Dodgeville .....	346,000	.....	.....
Potosi .....	290,000	.....	.....
Mineral Point .....	114,000	.....	.....
Totals .....	51,452,000	742,000	5,664,000

High-grade blende from separating plants in the field was shipped in volume from the following works.

	Lb.
Mineral Point Zinc Co. ....	6,900,000
National Separators .....	5,350,000
Wisconsin Zinc Co. ....	4,294,000
Benton Roasters .....	260,000
Linden Zinc Co. (Linden) .....	104,000
	16,908,000

The gross recovery of crude concentrate from all mines for the month aggregated 25,728 tons; net deliveries to smelters, including refinery ore and ore sent from mines to smelters direct 14,598 tons.

Sales and distribution of zinc ore were made during the

month to representatives of the following buying agencies. Mineral Point Zinc Co., 8968 tons; Grasselli Chemical Co., 6717; National Separators (Cuba), 5346; Wisconsin Zinc Co., 4798; American Zinc Co. (Hillsboro, Ill.), 1287; M. & H. Zinc Co. (LaSalle, Ill.), 960; Illinois Zinc Co. (Peru, Ill.), 616; Benton Roasters, 711; Linden Zinc Co. (Cuba), 538; Lanyon Zinc Co., 385; Edgar Zinc Co., 324; American Metals Co. (Langeloth, Pa.), 182 tons.

Considerable activity was seen in the Linden district where Kletsch Bros., of Milwaukee, purchased the Vial mine and the Wickes mine equipment. The latter was hastily dismantled and removed to the new mine site. On the Kickapoo lease the Milwaukee-Linden Development Co. drove a cross-cut to develop disseminated ore deposits. Rich borings on adjoining leaseholds was the main objective in this drive. Work of building a new mill on Optimo mine No. 4 has been suspended for the winter. This followed the shutting down of the Spring-Hill Mining Co., which became involved and was placed in the hands of a receiver, and it was stated that the Optimo company was negotiating for taking over the Spring-Hill mine and equipment. The Gilman mine, one of the best producers in the district, has nearly run its course, and the miners are pulling pillars. The mine is owned by the Milwaukee-Linden Development Co., formerly known as the Saxe-Pollard company.

A new industry spur about three miles long has been completed to the big zinc-ore refinery of the Wisconsin Zinc Co. at New Diggings, the cost of construction being borne by the main operating groups found in this section, namely, Wisconsin Zinc Co., New Jersey Zinc Co., Vinegar Hill Zinc Co., and the Fields Mining & Milling Co. of Chicago. Trains are in operation, connection having been made with the main line of the Chicago & Northwestern, three miles south of Benton. The new spur is giving great impetus to zinc mining in this section and many outlying producers are already engaged in building macadam roads to connect with the terminal of the new spur.

## HOUGHTON, MICHIGAN

QUINCY.—MOHAWK.—ISLE ROYALE.—ALLOUEZ.—LA SALLE.

The one absorbing topic of conversation among the copper-mining interests of the Lake Superior district is the attitude of the Government in the regulation of prices for the output after January 1. While every effort is being made to main-

tenance underground man can earn is at least 25% higher than at any previous time the fact remains that a shortage of labor continues. At Calumet the trammer that cannot average \$100 per month now is a pretty slow worker. A man with a good physique can earn more money than the man who has the engineering ability to map out his work for him. Yet the shortage continues at most of the mines.—The costs of producing copper at all of the mines in the Lake district will be higher in 1917 when the books are made up than ever before,

MASS COPPER IN THE QUINCY

not even excepting the year of the strike 1913, in most of the mines. In addition to the top notch wages, to the 100% average increase in practically everything that the mining companies have to buy, to the shortage of labor, most of the mining companies during the year have laid out enormous sums for high-cost construction-work. While homes for employees and buildings for surface use cost more this year than ordinarily, the fact is that these improvements were absolutely necessary, especially the buildings for the higher-class workmen. And the advance contracts made early in the year assured the corporations profit enough to pay for these necessary expenditures.

Never in the history of Quincy has there been such an unusual amount of mass copper secured as is now going directly to the smelter from this mine. It is coming in such large pieces that special methods for handling it, including a block and tackle at the shaft-house, are necessary. Chunks weighing eight tons are not unusual. The extent of this rich showing is not yet realized. It has been opened at 6500 ft.—Tonnage from the Kearsarges is increasing, the North Kearsarge contributing materially to the increase and the total from the Kearsarges and the old Osceola makes an average contribution in ore output equal to that which the Ahmeek secures, although, of course, the copper output is not as large. Last week the Kearsarges showed better than 80 cars per day, the grade of ore being a little better than average.—Mohawk is securing more men and increasing its output of ore; unless held up by snow storms it will make a better average in December. At present it is handling 70 cars of ore per day. Wolverine, the other producing Stanton property, is running 40 cars per day.—Production from the Isle Royale constantly increases. The three-stamp mill on the south side of Portage lake is running to full capacity. In addition to this the ore handled at the Point Mills plant, across the lake, has been increased from 12 to 20 carloads per day.—Ahmeek maintains production at 4700 tons per day.

Allouez has a substantial amount charged to plant improvements this year. Many new boilers have been added, and the whole surface plant gradually is being rehabilitated. An output of 1800 tons per day is being maintained.—Cherokee continues to find small mass and shot copper east of the 420-ft. level. East and west drifts on this level are in 70 ft.—The

MINING COPPER IN MICHIGAN

tain production up to normal conditions this is quite out of the question at the present time for two reasons. One is the shortage of men, 2000 having left to join the army; the other is the impossibility of securing good men by importation. The natural source of trammer supply, Europe, has been shut off for four years. Notwithstanding that the wage an av-

operations discontinued on account of lack of money and inability to interest capital. The property is owned by Duluth people. The land comprises 340 acres south-east of the Phoenix.—Stoping is being done only from the No. 1 shaft to the 15th level at the La Salle. Ore shipments run 500 tons per day, half from this shaft and half from No. 2. At No. 2 shaft driving is being done on the bottom on the 21st level. The La Salle shipped 15,600 tons in November.—The three mines of the Copper Range Co. are maintaining their production of copper. There may be a slight falling off for the November output but the total ore-tonnage for the month was the same as for October, both under the monthly average for 1916. Champion is now running better than 60,000 tons per month, Baltic 30,000, and Trimountain 20,000 tons. There was a slight increase in tonnage from Trimountain last month and a comparative falling off in Baltic. The general grade of ore was therefore not any better in November than in October. General underground conditions at the Champion are good. In the southerly shafts the showing has not improved of late but in the lower levels there are bunches of spectacular richness.

Production of ore from South Lake last month was 2345 tons.—The Lake output last month was 6000 tons.—Following the suspension of work at the Adventure the mine shipped 35 tons to the mill.—Ahmeek continues to break records. Its total output of ore now runs close to the combined output of the three Copper Range mines. Last month Ahmeek shipped 104,000 tons.—November showed a slight falling off in Franklin's output, which was 27,720 tons.—Mass is gradually increasing its output, now running 1000 tons per day; last month the output was 19,000 tons.—Superior shows a small increase for November. During November, Calumet & Hecla shipped 245,000; Isle Royale 13,000 to Point Mills plant and 54,000 to its own mill at Pilgrim; Osceola 97,500 tons.—At Seneca one boiler is working, one stack up and another ready to set up, and part of mining crew assembled. All machinery has been erected. Mining will start January 1.

The output of ore from Hancock Consolidated was 22,879 tons for November, a decline from the October one, due to shortage of labor. Indications point to better record for December.—There is no immediate intention of suspending operations at the Michigan, which now has its shaft down 120 ft.; a loading-station will soon be cut. Developments on the seventh level have been fairly good, particularly the drift and the cross-cut. This work is on the Ogimah lode.—While no Calumet & Hecla official is willing to admit that the White Pine, its Ontonagon county subsidiary, has little more than a fighting chance to become a big profit-maker, the assertion I made three years ago that the White Pine might some day take the place of the Calumet conglomerate is now more likely to be verified than at any time since this property was opened. The truth is that the Calumet & Hecla has got back the money it paid out for the opening of the White Pine.—There will be no further shipments of copper from this district by water this year. But rail shipments already are going forward for Government use.

### TONOPAH, NEVADA

TONOPAH MINING.—TONOPAH EXTENSION.—TONOPAH BELMONT.  
—WEST END CONSOLIDATED.—MACNAMARA.—JIM BUTLER.

Last week the Tonopah Mining Co. milled 2650 tons of ore averaging \$10.50 per ton. At the Silver Top 93 ft. of development has been done, 22 ft. at the Mizpah, and 90 ft. at the Sandgrass. At the Silver Top on the 340-ft. level the big stope on the Valley View vein has been filled with waste drawn from the surface, and high-grade ore is being taken from the hanging wall. Last week's production was 3050 tons.—The Tonopah Extension Mining Co. shipped 24 bars of bullion, valued

at \$47,000. This is the final November clean-up. At the No. 2 shaft 96 ft. of development, has been done and 144 ft. at the Victor. On the 550-ft. level of the No. 2 shaft, raise No. 814 continued to advance on a 2-ft. face of ore. On the 1350-ft. level cross-cut No. 510 cut a vein showing 3 ft. of ore. East intermediate drift No. 505 continues on a 3-ft. face of ore. At the Victor on the 1440-ft. level cross-cut 608 cut a 2-ft. vein of ore. On the 1540-ft. level winze 1501 continued to advance on a full face of good ore. On the 1680-ft. level 1600 south cross-cut advanced 51 ft., while 1600 west drift advanced 24 ft., showing 5 ft. of ore. The production the past week was 2380 tons.—The Tonopah Belmont Development Co. declared the regular quarterly dividend of 12½c. per share. The plant at Millers is being dismantled and the machinery distributed between the Belmont mill at Tonopah, the Belmont-Wagner mill at Telluride, Colorado, and the Eagle Shawmut mill at Tuolumne, California. Considerable development is being done on the 800-ft. level. On the 1100-ft. level raise No. 91 on the Belmont vein holed through into the 1000-ft. level, exposing medium-grade ore. Raise No. 93 on the Western vein is unchanged. Development has been resumed on the 1200-ft. level, which is the deepest level. Raise No. 58 from the west cross-cut No. 6 is prospecting for the faulted segment of the Shaft vein. Last week's production was 2767 tons.—The West End Consolidated Mining Co. shipped 30 bars of bullion, valued at \$49,845, which represents the final clean-up for November. At the Ohio shaft drift No. 526 made a connection with the 512 cross-cut. Drifts 535 and 536 continue in good ore. Winze 534, which has been sunk 35 ft. below the drift, shows excellent ore. Raise No. 814 on the 800-ft. level has advanced 60 ft. At the West End preparatory work on the 800-ft. level has been finished, and a cross-cut will be started to the Ohio. The output the past week was 1099 tons. At the Halifax Tonopah cross-cut 1708 on the 1700-ft. level has been started to avoid the heavy ground and large flow of water in the 1704 cross-cut. Cross-cuts 1018 and 1256 continue to make good progress.—The MacNamara Mining Co. shipped the final clean-up of bullion for November. The value of the shipment was \$10,804. Cross-cut 700 on the 700-ft. level advanced 54 ft. in Montana breccia the past week. On the 725-ft. level drift No. 19 advanced on good ore, while raise No. 815 on the 800-ft. level continues in low-grade ore. The production for the past week was 541 tons.—The Jim Butler Tonopah Mining Co. is now shipping its ore to the Belmont mill for treatment, instead of shipping it to the plant at Millers. This arrangement will benefit both companies, as the Jim Butler saves the railroad haul to Millers, and the Belmont mill will more nearly reach its full capacity. Raise No. 369 on the 2nd level of the Wandering Boy continues on a 3-ft. face of fair ore. Raise No. 372 on the same vein is making good progress on a 2-ft. face of medium-grade ore. Raise No. 373, which was started to pick up the faulted segment of the vein, shows a full face of low-grade ore. The production the past week was 247 tons.—The Montana produced 122 tons, making the week's production at Tonopah 10,206 tons with a gross value of \$178,605.

At the Cash Boy the west drift from the winze on the 1700-ft. level has been extended in the foot-wall and stoping is now being done in good ore. With the completion of the raise to the intermediate above, stoping has commenced on the east side of the winze as well. Lack of cars has prevented shipments of ore.—The North Star continues to raise from the 1050-ft. level on a good grade of ore. The production the past week was 56 tons.—The strike at Gold Mountain, on the Tonopah Divide Mining Co. estate, was made at a depth of 150 ft. It is reported that the vein has been cross-cut for 27 ft., showing good silver-sulphide ore. The orebody does not outcrop. The property is equipped with a compressor and jack-hammer drills. The Taylor-Govan claims on the west have been purchased by the Tonopah Divide Mining Company.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—It is reported that several thousand tons of good-grade vanadium and gold ore have been blocked out by the Dragon Mining & Development Co.—A serious break-down of the hoist at the boundary shaft of the Dragon copper lease will cause a shut-down of 30 days.

Bisbee, December 7.

(Special Correspondence.)—The Trinity Copper Co., which has been organized recently, is doing considerable development and construction work on its property in the northern part of the Swisshelm mountains. A 3-ton motor truck and hoist have been purchased and are on the property and a compressor and drill sharpener have been ordered. The ore carries silver, copper, lead, and zinc, while at one point high-grade bismuth ore has been exposed. About 20 men are employed under the superintendence of D. H. Crane.—Adjoining this property to the north is the Scheerer property, which has produced considerable lead-silver ore in the past. The property is now being worked under lease and bond and several carloads of lead-silver ore have been shipped during the past few months from the 200-ft. level. Some high-grade wulfenite has been mined and shipped from this level.—To the east of the Scheerer property is the Heney, from which is being taken high-grade silver-lead ore while high-grade zinc ore, in the form of calamine, has recently been discovered.—The Central Butte Mining Co., four miles south of Pearce, has seven men at work. It has widened the main shaft to the 200-ft. level and is now cutting a station. High-grade silver-copper ore is being taken from some surface workings.—The Warren Basin Copper Mining Co., in the Mule mountains, about five miles east of Warren, has started development work. Contractors have been engaged to sink a shaft to intersect a vein showing good copper-silver ore at the surface.—To the south of this property, Alfred Paul and associates of Douglas have shipped several carloads of manganese ore during the past few months.

Douglas, December 11.

### GILA COUNTY

(Special Correspondence.)—The Old Dominion Copper Co. is working at full capacity in all departments. The smelter produced 3,000,000 lb. of copper for November. The cutting of the 1900-ft. station of the A shaft has been started, and as soon as completed sinking will be continued to the 2100-ft. level.—Lawton and Pollard have purchased the Burro pack outfit of the Ray Silver-Lead Mining Co. and have moved it to the McCallum claims from which five carloads of high-grade ore will be shipped per month.—The steel-work of the addition to the Hayden smelter will be completed in January; the brick-work of the furnace is almost finished. Excavation for the erection of the coal-grinding plant is under way; in future coal dust will be used as fuel throughout the smelter.

Globe, December 8.

### MARICOPA COUNTY

(Special Correspondence.)—It is reported that the mine of the Consolidated Arizona Smelting Co. is ready for a larger production of ore, and the mill has been producing more con-

centrate than can be handled at the smelter. This excess, however, will be taken care of when the new roasting-plant is completed. At the Blue Bell mines the shaft is now down 1200 ft., the station cut, and development on that level about to commence.—The Noble Electric Steel Co. is working a large force of men on its manganese property, near Aguila, which was purchased last summer.—The Dolbeer interests are also pushing development on their property in the same district.—It is rumored that a smelter will be erected for ferro-manganese in the Aguila district.

Phoenix, December 7.

### MOHAVE COUNTY

(Special Correspondence.)—Two different companies are operating on different parts of the Old McCracken mine. A road is being built from the mine to Yucca, the nearest railroad point.—The Hercules mine has commenced stoping on the 250-ft. level, and a good grade of ore is being hoisted.

Kingman, December 7.

(Special Correspondence.)—The discovery of ore made in the Gray Eagle claim of the Tom Reed Gold Mines Co. is regarded as the most important made in the district since the Aztec orebody was opened up last year. The Gray Eagle is directly south of the Big Jim claim of the United Eastern Mining Co. Oscar H. Hershey, who has made a study of the Tom Reed property, reported that in his opinion the Aztec-Big Jim vein was faulted and thrown to the south several hundred feet. To explore the faulted apex, the Gray Eagle shaft was sunk and a cross-cut run south to the vein. When first cut it gave little promise, being narrow and barren, but a drift was started toward the south and the vein was found to widen and at 25 ft. from the cross-cut to carry commercial ore. The drift is now in about 75 ft.; for the last 50 ft. the ore has averaged \$20 per ton in gold. The vein runs in a north-westerly direction and the drift is still about 500 ft. from the end-line of the Red Lion Mining Co.'s property. The probability is that the ore-shoot extends farther than the property line, as a similar orebody on the lower portion of the vein extends for over 1000 ft. on Aztec and Big Jim ground. Since the discovery the stock of the company has more than doubled in value, and is now selling at 79c. per share.—The Telluride will start exploration work with drills very soon, and the Red Lion shaft, already down nearly 100 ft., will be sunk to the 400 or 500-ft. level within the next few months. Shaft-sinking is now under way at the Gold Ore, the Record Lode, and the Oatman Southern; cross-cutting is proceeding at the United Oatman, the Oatman United, the United Northern, and the old Gold Road property. Development work will be resumed on the Gold Road Bonanza and the Arizona Moss Back.—The United Eastern main shaft has reached its objective. As soon as a sump is sunk and a station prepared, cross-cutting will be started.

Oatman, December 10.

### PINAL COUNTY

(Special Correspondence.)—It is reported that a high-grade gold strike has been made by the Queen Creek Copper Co. at Superior. A rich strike has also been made at the Fortuna Consolidated.

Florence, December 8.

## SANTA CRUZ COUNTY

(Special Correspondence.)—It is reported that J. W. Bible of New Mexico has purchased the Australitz mine in the Oro Blanco district.

Nogales, December 6.

## YAVAPAI COUNTY

(Special Correspondence.)—A motion has been made to throw the Hull Copper Co. into the hands of a receiver that will handle the affairs of the company during the litigation now on. The Blue Jacket mine has started to ship to Humboldt, and development work has been resumed.

Prescott, December 7.

## YUMA COUNTY

(Special Correspondence.)—N. D. MacMyers of Prescott has taken a two-years bond and lease on the Dream Creek Copper Co., five miles west of Salome.

Yuma, December 8.

## CALIFORNIA

## ELDORADO COUNTY

(Special Correspondence.)—The Christiana Copper Co., which for the last two months has been unwatering and developing the old Seven Bells copper mine on the Charles Worthington place, has uncovered a fair-size body of high-grade copper ore and is erecting machinery. Frank C. Fox, manager, has purchased and will erect crushing and jig-concentrating machines.—The principal mines, mining properties, and ore deposits, in the county are being tabulated and indexed by Burr Evans, mining engineer of Placerville. Mr. Evans reports there is considerable inquiry and a good demand for properties containing gold, silver, copper, cinnabar, lead, zinc, cobalt, nickel, molybdenum, tungsten, manganese, chrome, strontium, barytes, bauxite, and magnesite.—As soon as the necessary equipment can be obtained a new double-compartment shaft will be sunk to the 600-ft. level, with three-shift crews sinking continuously, on the Shan Tsz gold-quartz mine, situated just four miles south-west of Placerville. H. DeC. Richards, of San Francisco, the supervising engineer, was on the property on November 25 to put things in readiness for starting the work. The Shan Tsz mine, which is owned by New York capitalists, is one of the best equipped gold quartz mines in Eldorado county. It contains a modern electric power and light plant and a 60-ton mill.

Placerville, December 7.

## FRESNO COUNTY

(Special Correspondence.)—The Copper King Mining Co. has merged the Copper King mine with the Wabash, Copper King Extension, Kneiper, and Davis properties, giving the company control of 745 acres of land on the foothill copper belt of California. The work of developing the property is being pressed; several shipments to the Kennett and Tacoma smelters have been made and the property is expected to be shipping 50 tons of ore daily inside of 90 days. Ore shipped averages 7½% copper, 16% sulphur, 28% iron, with \$1.80 in gold and one ounce of silver per ton. N. Treloar, of Salt Lake City, formerly manager for the Calaveras Consolidated, has been appointed general manager and engineer, having arrived at Copper King and taken charge of the property on December 12.

Fresno, December 12.

## INYO COUNTY

(Special Correspondence.)—The Friday silver-lead property, 2½ miles from Queen station, has been purchased by Michael Yalovica and associates of Goldfield for a reputed price of \$40,000. A cash payment has been made. A little work has been done near the surface, and a 30-in. shoot of \$50 ore exposed. One shipment, averaging \$140 per ton, has been made. Silver predominates, but some lead and a little gold occurs.

Bishop, December 4.

## NEVADA COUNTY

The North Star Mines Co. has declared a dividend of 60c., payable December 22. During the current year the company has disbursed \$250,000, bringing its total disbursement to \$5,337,040.

## TRINITY COUNTY

(Special Correspondence.)—The dredge of the Pacific Gold Dredging Co., which was moved four miles from the mouth of Morrison gulch to Carrville, has been running a week in its new location. The all-steel craft had to be torn to pieces to move it to the new site.

Carrville, December 11.

(Special Correspondence.)—The Bablew Mining Co. is equipped for steady production during the winter. One giant will be operated on the gravel bank, and a second monitor employed to clear away tailing. Extensive development work has been carried on under the new management and a large area of productive ground proved. The holdings are on the west end of the Paulsen ranch. V. P. Demens is manager.—The Jennings Gold Mining Co. is preparing for extensive hydraulicking along the Trinity river, five miles from Lewiston. Water is pumped into a reservoir 220 ft. above the mine, the pump being operated by a 200-hp. electric motor; 12 men are employed under Fred Dorman.—Dredging is quite active in this county. The Pacific Dredging Co. has re-built its steel dredge near Carrville. The deposits have been thoroughly tested and can be advantageously worked.—The Trinity Dredging Co. is operating near Lewiston with good results.—Near Trinity Center the Estabrook Gold Dredging Co. is building a large boat. Unlike the newer dredges, the Estabrook dredge will have a wooden hull.—Prospecting of placer ground by dredging companies is active along the Trinity and tributary streams.

Lewiston, December 10.

## COLORADO

## CLEAR CREEK COUNTY

The Wasatch-Colorado Mining Co. at Silver Plume is working three shifts continuously and shipping 200 tons of lead-zinc ore per week.—The Scepter Mining Co. has completed its tramway from Democrat mountain to Georgetown, a distance of nearly two miles, and expects to start shipping shortly. J. C. Hershey is manager.—The Smuggler is making regular shipments to the Idaho Springs mill. J. Simpson is manager.

Grading for the new concentration-mill at Urad for the treatment of molybdenum ore has been completed and some of the foundations are in place. A 2000-ft. adit is being driven, and from the end a raise will be put up to connect with the surface and give ventilation. The ore occurs in a porphyry dike which seems to be impregnated through its whole width with molybdenite. The ore, after coarse crushing, will be ground finely in ball and tube-mills and then subjected to flotation.

## LA PLATA COUNTY

(Special Correspondence.)—In the issue of November 17 it is stated that the American Smelting & Refining Co. had closed its plant at Durango on November 1. Mr. Gilbert's statement refers to the Silver Lake mill at Silverton, which has been run as a custom mill for the last few years, and not to the Durango smelter.

Colorado Springs, December 4.

## TELLER COUNTY

(Special Correspondence.)—The production by lessees of the El Paso Consolidated Gold Mining Co. during November totaled 300 tons of \$18 to \$20 grade.—The properties of the Sedan Gold Mining Co., on Galena hill, were sold under a judgment issued from the District Court of El Paso county on December 8 to Hildreth Frost of Cripple Creek and Colorado

Springs for \$20,257, including costs.—The shaft on the Rose Nicol property, on Battle mountain, was sunk 75 ft. during November by John Nichols, superintendent for the Camp Bird M. L. & P. Co., holding a 6-year lease on the property. It is a two-compartment shaft 4½ by 9 ft. in the clear.—The Victory Gold Mining Co., operating the Prince Albert group on Beacon hill under bond and lease, has commenced shipping from the Beacon claim.—The shaft on the Index property on Gold hill is being re-timbered and the mine machinery overhauled. The property has been leased to the El Paso Extension Co. Al Campbell is superintendent.—The Roosevelt tunnel of the Cripple Creek Deep Drainage & Tunnel Co. was advanced 115 ft. in November and in addition the Cresson drifts extended 43 ft., making a total of 158 ft. with only one shift working. The flow from the tunnel has decreased to 4150 gal. per minute. Cripple Creek, December 12.

C. H. Hays of Parkersburg, acting for the El Paso Extension Co., has taken a five-year bond and lease on the Index mine, and expects to start development shortly. The Index was formerly operated by the Index Mining Co., and there is said to be a considerable body of low-grade ore in the mine.

#### WASHINGTON COUNTY

The Akron Oil & Gas Co. has struck a six-foot stratum of oil-sand at 1992 ft. that is giving a flow of oil, estimated at over 100 bbl. per day. It is the intention of the company to continue sinking in the hope of getting a more extensive flow.

### IDAHO

#### BONNER COUNTY

The Armstead Mines, operating at Blacktail, on lake Pend Oreille, has broken another record for adit-driving. The main adit was advanced 489 ft. in the 28 working days of November. This performance beats the former record of 488 ft. in 29 working days of October.

#### LATAH COUNTY

A short course at the Idaho School of Mines, at Moscow, this winter is being planned with a view to preparing substitutes for the young professional and technical men who have gone to the army.

#### SHOSHONE COUNTY

The Hecla Mining Co. has declared a dividend of 5c. per share for December. The company has been paying 15c. per share but the low price of lead and uncertainty of the war-tax caused a reduction in the dividend rate for this month.

### MONTANA

#### FERGUSON COUNTY

(Special Correspondence.)—The plant at Hanover, being built by the Three Forks Portland Cement Co., is nearing completion.—The gypsum mill at Hanover has been operated regularly. The U. S. Gypsum Co. has done a considerable amount of development at its new Casofour plant, 10 miles east of Lewistown, and it will have a gypsum mill in operation next year.—At Kendall, North Moccasin mountains, the Barnes-King Development Co. is the chief operator. Work has been curtailed at the North Moccasin property on account of a labor shortage; nevertheless the company's output has averaged about \$18,000 per month during the past six months. The Kendall mine, owned by the Barnes-King, has been worked successfully under lease. Development work has been done at the West Kendall, the North Kendall, and some other properties.—The Spotted Horse, Maginness, and Cumberland mines at Maiden, in the Judith mountains, have been operated by lessees. The Cumberland has made a successful record, the lessees having found a large body of high-grade ore. Development work has been done at the War Eagle and other properties near Maiden. A new cyanide mill has been built

at Giltedge to treat low-grade ore and tailing from the old Gold Reef mill. N. J. Littlejohn, of Lewistown, has purchased the Mammoth property near Giltedge. It is equipped with a 50-ton cyanide plant. Development work this summer disclosed sufficient ore to justify operation of the mill next spring.—A good grade of copper ore has been found on the Sutter claims on Armell creek.—Silver-lead and zinc properties are active at Nelhart in the Little Belt mountains. Production is also coming from Wolf creek and near Monarch. Several properties that have been idle since the early nineties have been purchased or leased and re-opened this summer.

Lewistown, December 6.

### NEVADA

#### CLARK COUNTY

(Special Correspondence.)—From 75 to 100 tons of manganese ore is being shipped daily to Pittsburgh steel mills from a deposit recently opened 15 miles east of Las Vegas. The property is operated under lease by Connor, Gillin & McCoy, and a large tonnage of ore is exposed.—The main orebody has been recovered on the lowest level of the Yellow Pine Extension and is developing favorably. It ranges from six to seven feet wide and assays 35 to 40% zinc. A. J. Robins is manager.—High-grade copper ore has been uncovered in the adit of the Red Streak. The ore carries copper glance, and is said to be among the richest ever opened in this district. Alex. Anderson is superintendent.—Copper ore has been found in the lower adit at the Platino, 300 ft. below surface. In the upper level development of high-grade ore continues.—Development of the main lead-zinc orebody on the 700-ft. level of the Yellow Pine group, north of the shaft, is progressing satisfactorily. The ore assays as high as on the upper levels. A four-inch vein of high-grade copper has been found on the 700-ft. level; the first appearance of copper in the deep workings of the mine.

Goodsprings, December 3.

#### LANDER COUNTY

(Special Correspondence.)—The Mercury Mining Co. has opened an extensive deposit of cinnabar near Ione. The furnaces are being repaired, more workmen engaged, and arrangements made for a steady output.—A promising cinnabar deposit, carrying a little gold, has been found near Phonolite by Joseph Beck.—Lessees are opening high-grade silver ore on the Kattenhorn group, near Maysville.—The Kenzevich-Govich lease has shipped a car of selected ore assaying 100 to 400 oz. of silver. The Kenzevich-Sly lease is developing a shoot assaying 200 oz. of silver.—Shipments of copper ore are going to the Kennett smelter from the Edison lease at Copper Basin, near Battle Mountain. The shaft is down 170 ft. and at 160 ft. the orebody is 22 ft. wide and averages 12% copper; 70 cars have been shipped.—The Copper Canyon Co. has erected a hoist.—The Goff & McDonald leases are shipping high-grade ore.—At Galena, Johnson & McGregor have erected a small concentrator to treat their silver-lead ore. A large vein of medium-grade ore has been developed and silver-lead concentrate is being shipped to custom plants. Several properties in this section are active, and some good discoveries have been reported.

Austin, December 1.

### SOUTH DAKOTA

#### LAWRENCE COUNTY

(Special Correspondence.)—Announcement is made that the special dividend of \$1 per share will be paid to Homestake stockholders with the regular payment during December. This will make \$1.65 for the month and \$8.80 per share for the year. The total distributed to stockholders during the year will reach \$2,210,208. The second power plant on Spearfish creek has been completed and water will be turned into the

flume about the middle of December.—The Trojan company has completed changes in its milling plant enabling it to handle 500 tons daily. The Two Johns mine has been added to the Trojan present holdings and regular shipments of ore are being made. In addition to this some custom ores are being handled. The Republic property in Black Tail gulch, which is leased by the company, is supplying ore to the Trojan plant. Motor-trucks are used in transporting the ore from the mine to the nearest railroad point.—At the Montezuma & Whizzers, which is under bond to J. T. Millikin, diamond-drilling continues. Mr. Millikin recently purchased the Oro Hondo property, which he has been developing for the past two years. The Golden Reward Co. has men at work at the Gilt Edge Maid in the Galena district and the property will be thoroughly developed.

#### PENNINGTON COUNTY

The Homelode Co. has suspended mining and milling temporarily and will prospect by means of diamond-drilling.—The Blue Lead copper property near Hill City will be worked by the new owners. One car of ore has been shipped to the smelter.—One car of copper ore has been shipped from the Black Hills copper property near Rochford.

#### WASHINGTON

##### FERRY COUNTY

(Special Correspondence.)—During the month of November the mines of Republic yielded 7150 tons of ore, as follows: Northport Smelting & Refining Co., from the Lone Pine mine, 4000 tons; Lone Pine-Surprise Consolidated Mining Co., from the Last Chance mine 1250 tons, Knob Hill mine 700 tons, lessees from the Quilp mine 1000 tons, Rathfon Reduction Works 200 tons.—The Last Chance mine is now in excellent working condition. A drift on the 500-ft. level has been driven 200 ft. on the vein. The vein is from 6 to 14 ft. wide. A raise has been carried up from the 500-ft. level 40 ft. to the old Harper workings; the pay-shoot is 180 ft. long, the ore averaging around \$11 per ton. Stopping ground is now open from the 500-ft. level to the surface, and the ventilation is perfect throughout.

Republic, December 13.

#### STEVENS COUNTY

The first dividend to be declared by a magnesite company operating in this county is a 2% return to stockholders of the American Minerals Production Co., making a total of \$30,000. The company is quarrying on a big deposit west of the town of Valley, and has been shipping both crude and calcine material for several months. It is headed by Thomas W. Cole of Chicago. Work on the railroad from Valley to the quarries is being rushed.—A disputed point over magnesite operations on account of industrial insurance applying has been ruled upon by the State Insurance Commission, with a decision that taking out magnesite is quarrying and not mining and the hauling of the product to kilns is incidental to the quarry work. However, it is expected that magnesite operations will be classified as mining in the public mind regardless of the decision by the commission.

#### WHITMAN COUNTY

The School of Mines of the State College of Washington announces that beginning January 7, 1918, a 12-weeks course in mining will be offered to prospectors and mining operators of the North-West. Instruction will be given in mining, metallurgy, geology, and ore deposits, assaying, chemistry, surveying, and ore testing. These courses will be given in the winter School of Mines under a faculty of seven professors from the School of Mines, and the Departments of Geology and Chemistry. Certificates will be issued to those satisfactorily completing any of the courses. A fee of \$25 is charged. This is the only charge.

## PERSONAL

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

CARLOS W. VAN LAW is here.

ROBERT M. RAYMOND has returned to New York from Mexico.

C. F. BRANDT has returned to San Francisco from the Dutch East Indies.

JOHN BALLOT, chairman of Minerals Separation Ltd., is in San Francisco.

W. J. SHARWOOD, metallurgist at the Homestake, is here on a short holiday.

C. A. HOFFART has returned to Oroville from the Amur region of Siberia.

HARLOWE HARDINGE is First Lieutenant in the Signal Corps, A. E. F. in France.

W. A. PRICHARD has returned hither from New York, on his way back to Colombia.

RENSSELAER TOLL is at Secret Pass, near Kingman, Arizona, constructing a gold mill.

C. A. THOMAS, resident manager for the Yukon Gold Co., is now at Berkeley, California.

GELASIO CAETANI has been promoted to captain in the engineer corps of the Italian army.

E. L. S. WRAMPELMEIER, of Tucson, Arizona, has opened offices in the Hobart Bdg., San Francisco.

N. I. TRUSCHKOFF sailed on the 'Nippon Maru' for Yokohama on December 15, returning to Russia.

A. B. APPERSON, L. S. DINWOODY, and WILLIAM FOSTER, of Salt Lake City, were here during the past week.

DANIEL C. JACKLING has been selected by the Secretary of War to direct the construction of explosive-plants.

ANDREW NISBET has returned to California from the Federated Malay States, where he has been for the past three years.

C. J. HALL has returned from the Spassky copper mine, Siberia, and is now with the Garfield Smelting Co. at Garfield, Utah.

JACOB W. YOUNG has returned to Oakland from Alaska, having spent the summer on Slate creek, below the Chestochina glacier.

F. W. DRAPER has returned to San Francisco from the Verk Isetz copper mine, in the Ural region of Russia, and is now in New York.

P. G. BECKETT, who recently resigned as manager of the Dominion mine, has been appointed assistant to the president of the Phelps-Dodge Corporation.

N. TRELOAR, formerly manager of the Calaveras Con., has been appointed general manager and engineer of the Copper King mine in Fresno county, California.

AUGUSTUS MACDONALD has been appointed general superintendent of the mining and milling operations for the Primos Mining & Milling Co. at Lakewood, Colorado.

An unsigned letter from Washington, dated December 5, on 'Flotation Physics' has been received. The Editor desires to know the name of the writer.

JOHN H. BROWN died at Oakland on December 14. He was born in Pennsylvania 78 years ago and came to California across Panama in 1859, starting to mine at North San Juan in Nevada county and becoming superintendent of the American mine. In 1892 he went to Idaho and in 1893 he was appointed superintendent for the Leesburg Gold Mining Co. retaining this post for 10 years. In 1907 he went to Cobalt, Ontario, to take charge of stripping operations for the Nipissing company.

# THE METAL MARKET

## METAL PRICES

San Francisco, December 18

The production of copper at the Inspiration is only 2,500,000 lb. per month as compared with the nominal output of 10,500,000 to 11,000,000 lb. The shortage of labor is the cause. We understand that the company is engaging only the better type of American workmen.

Plans of the Guggenheims for the re-opening of the Chihuahua smelter in Mexico have been delayed owing to recent depredations of marauders in that section. At the operating points in Mexico which the American Smelting & Refining Co. has maintained none of the plants has been able to operate at capacity. With the demand for silver exceeding supply, enlarged operations by the Guggenheims in Mexico would result in some relief in this direction, although the greatest silver yield of Mexico comes from the southern part, practically inaccessible at present. Operations of the tin smelter of the American Smelting & Refining Co. in New Jersey have been showing a gradual increase and January output should be nearly up to capacity of 800 tons compared with 600 tons in October. Raw material comes from Bolivia in the shape of 60% product which the smelter—the only one in the United States—reduces to marketable form.

Samuel Montagu & Co. says: It has been reported from America, but not yet officially confirmed, that the British and United States governments have bought jointly 100,000,000 oz. of silver for delivery in 1918, of which 60,000,000 oz. is intended for India (at the rate of 5,000,000 oz. per month) and the remainder for the financing of troops in France and elsewhere. The rate indicated is 86c. for delivery in New York, and 85c. in San Francisco. The former figure works out at 40.11d. per standard ounce (based on 476¢, the present U. S. exchange). This would compare

favorably with 43.05d. per ounce standard, the minted value of the rupee, calculating at 15 rupees to the sovereign. Should the news be correct, the assurance of so substantial a price for silver should stimulate individual mines to increase their output and it is quite possible that the total of 100,000,000 oz., large though it be, will not represent half of the world's output for next year.

Under arrangements being made by the Tin Committee of the American Iron and Steel Institute, moderate amounts of Banca tin at 72c., Pittsburgh, continue to be supplied to those who can show that the metal is urgently required for work on Government orders. It transpires that the amount of tin commandeered by the Navy Department in store, New York, was comparatively small, and only represented lots stored in warehouses under bond to the Government. It is believed the Navy requirements are being arranged for by the Tin Committee, and that tin not required from said commandeered lots will be released.

The situation is serious, and the relief must come from new arrivals, therefore what the trade is eagerly praying for is news of free granting of permits for the stocks they have coming to them from London. Large shipments are expected from London, as a result of the successful negotiations of the Tin Committee. There must be a great curtailment in the production of non-essentials into which tin enters, and manufacturers should see to it that this is continued until the situation is relieved.

Neither spot Straits nor No. 1 Chinese tin is offering. A very small quantity of English Lamb & Flagg is on the market at 80c. per pound. Tin for shipment from London or Liverpool as soon as permit is obtained has been advanced sharply, 72c. now being asked. Tin for shipment from the East Indies, as soon as permit is obtained, is nominal at 71c., and February-March shipment at 70 cents.

# Eastern Metal Market

New York, December 12.

Price-regulation is the principal topic in the metal markets. With copper and tin under Government control, lead is soon expected to follow, and spelter next. Activity is limited in all markets.

Copper is unchanged at the controlled prices.

Tin continues to be scarce and to advance nominally.

Lead is inactive, but firm, at unchanged prices.

Zinc is lifeless and lower.

Antimony is dull but steady.

Aluminum is quiet and unchanged.

The chief topic in the steel circles is the question of a further revision of prices, those now in effect having been fixed to January 1. A conference was held in Washington this week, but the result seems to indicate that few, if any changes, will be made, and that present levels will continue for a considerable time, despite the desire of some in authority for lower prices in basic products. The severe weather has interfered with traffic and production. Hundreds of thousands of tons of steel for Europe are held up at Atlantic ports or elsewhere by freight congestion.

## COPPER

The market has settled down in such a routine of 'controlled activity' that no interest is taken in it. Practically it is bare of news. From indications the regulated Government distribution, as carried out by the Copper Producers' Committee, is working smoothly and to the entire satisfaction of consumers. Sales are being made rather freely to all consumers in large quantities at 23.50c. per lb., New York, for delivery in the first quarter, but very little is available for December except to those having Government contracts. The jobbing business is also proceeding smoothly at 24.67½c. per lb. or 5% above the Government price, and it is not unlikely that some sales are made at higher prices where the original cost was higher. The principal topic of interest now is the question of a revision of the fixed price of copper after January 31. In the original fixing of a price the end of January was put as the time limit for the application of the present 23.50c. price. A meeting is scheduled for Friday, December 14, to discuss the copper situation with the Government, including possibly the price question. The feeling in the trade is strong that if any re-adjustment is made it must be upward rather than downward, so as to stimulate production as much as possible. The sentiment, however, now seems to be that no change will be made at this time.

## TIN

It develops that many consumers are short of tin, some of them being large ones. On the other hand, it is a fact that one large consumer has lately sold spot Banca tin to needy users, refusing any to all others. In general, the market is extremely dull, due to lack of offers, and quotations have continued to advance; but in all cases they have been and are nominal. On December 5, 6, and 7 spot Straits sold at 85c., New York, and on December 10 and yesterday at 86c., New York, the highest ever recorded. Business yesterday and Monday was very light. Cables are abominably late, greatly retarding business. The American Iron and Steel Institute took actual control of the market on Monday, December 10, without any official announcement. There are urgent advocates that import restrictions and licenses on tin be done away with as superfluous, leaving absolute control of the metal in the hands of the American Iron and Steel Institute. Without doubt there are serious

delays and annoyances in this phase of the situation. There has been a moderate inquiry for prompt shipment from England, and a little business is reported at 71 to 72c., New York, subject to license. Arrivals to date, inclusive, have been 460 tons, with 4840 tons reported afloat. The London market is again higher. Yesterday the quotation for spot Straits was £299 per ton, or £5 higher than last week.

## LEAD

It is understood that the Government has closed for its requirements for the next 30 days, but the quantity and price are not announced. It is also expected that the price of lead will be fixed in a few days, but on what basis is still conjecture. The market in general has been quiet and without interest during the past week. It has been firm, with quotations unchanged at 6.50c., New York, or 6.37½c., St. Louis, in the outside market for early delivery. The 'Trust' price still stands at 6.25c., New York. Activity has been in spots, but the quantity sold has not been large. Producers are well sold up for six weeks to come.

## ZINC

Dealers are decidedly pessimistic and call the market an absolutely lifeless one, with the prospects not of the most encouraging nature. Until there is a balance between supply and demand conditions are likely to remain as they are, with buying at a low ebb and with prices falling. Some think that, because of the general dropping out of smelters here and there, this balance has about been reached. It is estimated by some that production has fallen off 30%, while others put it at 50%. It is probable that an accurate survey, were this possible, would put the reduction in output at 40%, but there are still enough producers to meet the poor demand so that quotations have gradually declined again until yesterday prime Western was quoted at 7.50c., St. Louis, or 7.75c., New York, for early delivery, with forward positions ¼ to ½c. higher. Galvanizers and brass makers are not in the market nor has the Government's programme for shells had any effect. When this materializes in orders, its volume will be large, but just what effect it will have on the market is a matter of speculation. Price-fixing has made no progress publicly, neither is it known how much the Government will need of the various grades. The entire situation is uncertain and unsatisfactory.

## ANTIMONY

The spurt in the market last week was short-lived. Attempts were evidently made to lift it on the strength of the effect of the embargo on imports, but this did not work out. Today the market is quiet at 15.25 to 15.50c. per lb., New York, duty paid, for the brands available.

## ALUMINUM

The market continues dull and quiet at 36 to 38c. per lb., New York, for No. 1 virgin metal, 98 to 99% pure.

## ORES

Tungsten: There is practically no change in prices, the range being from \$26 per unit for scheelite down to \$20 to \$24 per unit for wolframite and other grades as 60% concentrates. Sales have been made at these prices, but there is a tendency to quietness as the end of the year approaches.

Molybdenum and antimony: Molybdenum is strong, with the demand active. Small sales are reported at from \$2.20 to \$2.30 per lb. of MoS<sub>2</sub> in 90% concentrates. There is nothing new in antimony ore.

# INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

## ORONITE TO PREVENT DETERIORATION

In the State of Washington, on the Nisqually river near La Grande, is a municipal electric plant where current for light and power is manufactured for the city of Tacoma. From a dam higher up the river water is brought to the power-house

APPLYING ORONITE PAINT TO WATER-MAIN

MUNICIPAL WATER-MAIN PROTECTED BY ORONITE PAINT

by an aqueduct that passes through a mountain and spans the canyon. This conduit is 10 ft. diameter and 360 ft. from pier to pier. Two and one-half million cubic feet of water per hour flows through it, developing 20,000 kilowatts. Watchmen guard it night and day, for should anything happen to put it out of commission the Tacoma municipal light and power plant would cease operation. To safeguard this important link in the system against deterioration from atmospheric influences, were

the pipe unprotected, it was recently covered with 'Oronite' paint, which is especially adapted for use on metal surfaces.

## GAS AND GASOLINE-DRIVEN COMPRESSORS

The Chicago pneumatic 'simplite' valve, enclosed frame, self-oiling, gas and gasoline-driven compressors comprising classes N-SG and N-SGL are designed to meet the requirements of shops, mines, quarries, and construction projects where ease of management, dependability, and economy of operation are desired. They are particularly suited for the hard service conditions often encountered in connection with the use of rock-drills, pneumatic-tools, air-lift for water, and other appliances.

The compressors are of the horizontal, straight-line, single-stage, double-flywheel enclosed-frame type and are without delicate or complicated parts. Power and air-cylinders are closely connected tandem. Substantial cast-iron sub-bases, oak skids, or portable tanks are furnished as desired. Splash lubrication is employed for the main bearings, cross-head guides, wrist-pin and crank-pin, making the compressor practically self-oiling. The power-cylinder of the N-SG gas-driven machine is of a special design, valveless, two-cycle type with high-tension electric ignition. Close regulation is secured by means of a fly-ball governor, which regulates the gas and air admitted in accordance with the load-demand. Thorough scavenging of the cylinder is assured by a deflector on the piston. On the N-SGL a combined speed and pressure-governor regulates the amount of gasoline admitted to the cylinder. The outstanding feature of the air-end is the use of 'simplite' valves, which make small clearances and high efficiencies possible. The N-SG compressor will run satisfactorily on any natural or artificial gas containing 600 b.t.u. per cubic foot or over. This should not cause difficulty, since most artificial gases contain at least this

number of heat-units, and since natural gas for the most part has between 900 and 1100 b.t.u. The N-SGL is guaranteed to run satisfactorily on any grade of gasoline. These machines require little attention, being well suited to rough heavy duty under conditions which prevent the employment of a highly trained attendant.

Details will be found in bulletin 34-Y, which the Chicago Pneumatic Tool Co. will supply on request.

## IMPACT SCREENS

The Colorado Iron Works Co. states that, "the publicity given in your November 10 issue to the statement made in A. P. Watt's paper on 'Concentration Practice in South-East Missouri' that 'the impact-screen, as manufactured by the Colorado Iron Works Co., is being tested in one mine in the district' suggests that a correction might be made to counteract the probable impression that this apparatus has not yet taken its place as standard mill-equipment. The fact that the district has already made a decision in this direction is exemplified by the action of the St. Joseph Lead Co., which ordered its first 3 by 4-ft. impact-screen in December 1916, and speedily followed this with repeat orders for six screens in January 1917, three in August 1917, and three in November 1917."

## WOOD SELF-ROTATING HAMMER DRILL

The accompanying cut illustrates the construction of this light and efficient mechanism which is adapted to every purpose for which a hammer-drill can be employed. It is useful in road construction, quarrying, block-holing, and shaft-sinking. It can be operated either with steam or air, the drill-

steel is automatically rotated, and it is provided with an automatic lubricating device. The balanced valve travels only  $\frac{1}{8}$  in. from the centre in either direction, thus giving great length of wear. The drill-hole is automatically cleaned by pressure on the up-stroke of the piston. By pressing the button on the top of the chest full pressure is applied to the bottom of the hole through the steel, thus blowing out the cuttings. No collars are required on the steel. The drill-steel must rest against the anvil-block, not against the steel rotator, when collars are used. The piston is bell-shaped and does not crack or splinter at the end of the stroke as the force of the blow is received in the centre of the piston. Its length over-all is 22 in., the stroke is 2 in., the cylinder is 2 in. diam., and it takes a  $\frac{3}{4}$ -in. steel. The steam or air-connection is  $\frac{1}{2}$  in. It will drill a 6-ft hole with steam, and a 10-ft. hole with air. It weighs 44 lb. It is made by the Wood Drill Works, Paterson, New Jersey.

## INDUSTRIAL NOTES

The TUNGSTEN MINES Co. has removed its general offices from Los Angeles to San Francisco, and its headquarters are now at 58 Sutter street.

The LINK-BELT Co. has just issued an attractive pamphlet on 'The Ideal Drive for Clay-Working Machinery.' It describes the 'Link-Belt Silent Chain' as applied to the ponderous machinery used in the clay-working industries. This chain drive is guaranteed to maintain over 98% efficiency. The booklet is handsomely illustrated.

The Homestake Gold Mining Co., of South Dakota, has placed an order with the HARDINGE CONICAL MILL Co. for an 8-ft. conical ball-mill. This mill will work in competition and in conjunction with stamps. The Homestake plant now has over 1000 stamps in operation. The Hardinge company believes that this mill, occupying the space of 10 stamps, will do the work of 80 to 100 stamps.

'Turning Waste Into Profit' is the title of a book just issued by the PREST-O-LITE Co., Inc., of Indianapolis, Indiana. It is devoted to the possibilities of reclaiming broken and worn machinery and metal-parts for service by the oxy-acetylene process, and is the most complete and comprehensive book ever issued on this subject. Containing 82 illustrations, it pictures and describes representative examples of reclamation welding in practically every field of the industrial world.

The second of a series of catalogues of industrial motors has just been issued by the WESTINGHOUSE ELECTRIC & MANUFACTURING Co. of East Pittsburgh, Pa. This is known as Catalogue 30, and covers all the direct-current motors and generators made by this company for industrial service. Several pages are given to general information regarding questions of ordering, classification, and the selection of direct-current motors; there then follows complete description, rating, and dimensions for type SK commutating-pole motors, modifications of type SK elevator-motors, reversing-planer motor equipment, type CD motors, head-stock equipment for wood-working plants, type SK and CD motor-generators and arc-welding equipment. Much new information is given, especially on such subjects as arc-welding, head-stock equipment, motion-picture service, and battery-charging service.

'Du Pont Products' is the title of a handsomely printed and bound booklet, issued by the E. I. DU PONT DE NEMOURS & Co. of Wilmington, Delaware. The great business of this corporation has developed along the self-protective line of co-ordinated industries. It is becoming the newest method in American commercial expansion; the U. S. Steel is a notable example, covering iron, steel, zinc, acids, coal, coke, and a multitude of chemicals coming from the utilization of what would otherwise be waste-products in coking. The Semet-Solvay is another brilliant example of the same system. Most remarkable is the complex development of associated industries built up in recent years by a company that had but a single powder factory 40 years ago. Powder is still the pivotal enterprise, but around it cluster factories for making sulphuric, nitric, hydrochloric, acetic, picric, lactic, and other acids; celluloid, varnish, paints, lithophone, alum, aniline, creosotes, 'fabrikoid', which is a remarkable leather substitute, pyralin, rubber-cloth, an enormous list of chemicals, and every known explosive for which a demand exists. This booklet gives an account of the most commonly used products of the Du Pont corporation, and it contains in addition a list of the various branches of industry under which the articles made by this house and applicable to that industry are enumerated. For example, under 'Tire (Rubber) Makers', are given, "Naphtha, for solvent; benzol, for solvent; nitre-cake, for de-fiberizing rubber scrap; creosotes, for solvent in reclaiming scraps; litharge, a component of rubber-tires; paints and varnishes, for plants, equipment, and offices."

Engineers and Dredge Builders

Agents for Bucyrus Placer Dredges on the  
Pacific Coast, in British Columbia and Alaska

**A** HAPPY NEW YEAR to the mining industry: good prices for metals and such use of them as shall enable the Allies to win a victorious peace!

**T**AXATION is a subject in which everybody is interested at this time. On another page we publish an analysis and a discussion of the excess-profit tax, with suggested modifications, by Mr. Philip Wiseman, the president of the United Eastern Mining Company, the most successful gold-mining enterprise in the Oatman district of Arizona. The fact that this memorandum was not intended originally for publication makes it only the more interesting and convincing. It seems to us to be a sane and reasonable protest, not by a man or by a group of men anxious to evade making their proportionate contribution to the national treasury at a time of crisis, but by citizens having a valid objection to inequitable taxation.

**I**N this issue we publish a description of the Government Railroad in Alaska, an enterprise of the greatest importance to the welfare and development of the North. This article is written by Mr. Theodore Pilger, a mining engineer from Butte, who spent the past summer in a tour of inspection in southern and south-eastern Alaska. The excellent map that goes with the text will indicate the route to be followed by the railway into the heart of the interior, or 'inside,' as the Alaskans call the region across the coast range, in distinction to the 'outside,' meaning the rest of the world. We join with our friends up north in hoping that this railroad will give aid to the exploration and development of a great mineral region. In the news columns of recent issues we have published notes, by Mr. Pilger, describing progress in the Willow Creek, Cache Creek, and Copper River districts.

**T**HEORIES of delicately balanced conservation and utilization of mineral resources are giving way to practical economic development for the welfare of the nation. The plans brewing in Congress for a vast expansion of coal-mining and oil-production on previously withdrawn areas in the West, go so far as the proposal, made by congressmen who hold to the older standards, to recognize again the right of acquiring ownership in fee simple. This marks a return to the historic democratic principles of American development, which is

founded on that sort of individual initiative and strength that actual possession encourages. The Government now seems disposed to take a true forward look toward the effective unfolding of the resources of the West.

**F**ROM Cambridge comes the announcement of Mr. Theodore W. Richards, the president of the American Association for the Advancement of Science, requesting members not to attend the annual meeting at Pittsburgh "unless assured that they can render an important service to the country by doing so." This is said in order to lessen the difficulties of transportation, already acute. It is a wise move. Unnecessary travel is to be deprecated. Tourists are an absurdity in times like these. We read the other day, among a list of hotel arrivals, the name "A. Vandenberg, tourist," as having landed from an incoming Australian steamer. A man that starts to go on a tour at this juncture in the world's history ought to be placed in a lunatic asylum or tied in a sack and dropped in the nearest large body of salt water.

**T**HE threat to place an embargo on freightage to gold mines has been disclaimed by Mr. R. S. Lovett, the chairman of the Priority Board. We are glad of that. The intimation that such freightage would be declared non-essential to the War came to us from such a source as to indicate that it was no false alarm, although now disavowed. To Senator Pittman of Nevada, we believe, is to be given the credit for putting the matter in a proper light before the authorities at Washington. We are amused to learn that sundry gentlemen in San Francisco suggested that the story was concocted to provide a Hindenburg retreat for the promoters of the two unfortunate gold-mining enterprises at Juneau. This is a fallacy, which is punctured further by the letter from Mr. J. Parke Channing dated December 3, on the subject, in our New York contemporary's issue of December 8. The luncheon at the Pacific Union Club given by Mr. F. W. Bradley in honor of Mr. Hennen Jennings and with the purpose of enabling Mr. Jennings to meet a number of representatives of the gold-mining industry in California took place on December 5. Mr. Jennings, in his capacity of consulting engineer to the U. S. Bureau of Mines, had come to San Francisco to obtain data on the status of gold mining in its relation to the War and

to the taxation incident thereto. We take the opportunity of suggesting to managers of gold mines that they put themselves in communication with Mr. Jennings, so as to assist in the gathering of the data required by the Bureau of Mines.

BRET HARTE has said poetically that "the ways of a man with a maid be strange, yet simple and tame to the ways of a man with a mine when buying or selling that same." To the prospectus we owe as many humorous errors as to the school-boy's essays. The latest appears in the advertisement of the Gold Cross Mining Company, which offers stock for sale at St. Louis, to operate a mine near Prescott, Arizona. The general nature of the business includes "to bore, drill, prospect, and mine" for sundry metals, including "steel" and "brass." No wonder that one of our prospector friends writes to say that this is "something new" to him, and inquires if we know of "any books on the geology of brass." He adds that "one of the parties is a mining engineer with a great long handle to his name and knows all about brass." We expect he does. He must be an embodiment of it. As far as we know, no vein or other natural deposits of brass or even 'steel' have been discovered in Arizona or in any other of our rich and varied mineral regions, but both these products are made artificially for the purpose of facilitating the circulation of money, particularly from the pockets of the simple to those of the sophisticated.

DRAFTING of undergraduates in colleges and universities, especially young men dedicated to scientific pursuits, has appeared unwise to us and to many patriotic Americans. We have urged that Congress discriminate in favor of men already matriculated and in line of training for such scientific work as is of economic importance. It is pleasing now to record that the California State Council of Defense has directed attention to this subject, and that this body regards as an ineffectual solution of the problem the request sent from the War Department that students of science continue their studies until drafted, without previous enlistment. Indeed, it is ineffectual. Young men on the draft-list are kept in such uncertainty as to their future movements that it becomes quite impossible to concentrate the mind upon study in a way that can lead to good results. We know of cases where drafted men have been kept dangling for months, with orders to report at a training camp on a certain date, countermanded a few days later by orders to look forward to service next April, followed in a few days by notification to keep in readiness to report on call within 24 hours. Any man who has ever done serious study knows that it is impossible under such conditions of mental distraction as must result from these conflicting orders. Again we insist that our political leaders will ultimately have cause to repent their folly in having depleted the engineering and mining schools of the younger generation of specialists in

case the War should continue a year or two longer. Trained men will be needed in greater numbers for the vitally important industrial ranks that make it possible for other men to fight for country and home on the battle-front. It is not exemption from military service that we advocate; it is the performance of national service in the technical branches where they are peculiarly and urgently required. It is a truism to assert that the scientific army is hardly less important than the army in the trenches. We would soon discover that fact calamitously if we had to recruit incompetents to do the work in our mines, our smelters, our steel works, and our chemical factories. A practical solution of the matter would be to detail training officers to the important universities, enlist the students in the army, and give them daily military training, but under regulations ensuring their continuance in college until graduation, with the outlook thereafter corresponding to their special aptitude and to the Government's greater needs at that particular time. We commend this to the serious consideration of Congress.

## War Minerals

In previous issues we have drawn passing attention to the importance of the work being done by the War Minerals Committee, of which Mr. William Y. Westervelt is chairman, assisted by such representative economists and geologists as Messrs. Alfred G. White, David White, and W. O. Hotchkiss. The good work being done by these gentlemen is to be aided by a bill already drafted and submitted to the Mines Committees of both houses of Congress. This, therefore, is a good time to bespeak the interest of our readers. Even the man in the street is aware that this is a war in which metals are required in enormous amount; our readers, taking part directly or indirectly in the production of metals and minerals, are cognizant of the need for accelerating every effort in creating an adequate supply of the material used in the manufacture of munitions. The War found us unprepared to supply many important ingredients, which we had been accustomed to import, some of them from the enemy countries and others from the allied countries now unable to export to us on account of the scarcity of shipping. Domestic production has been hindered by labor problems, railway congestion, the incidence of new taxation, and other discouragements. In order to overcome these difficulties and to encourage domestic production it is necessary that authority be given to the President whereby he may have wide powers for this particular purpose. The bill to be submitted to Congress is modeled upon that which authorized the formation of the Food and Fuel administrations. The aim is to provide authority for stimulating the production of ores and minerals, and to conserve the supply of them, to assure equitable distribution, to improve and direct utilization, to prevent manipulation, to lessen our dependence upon importation, and to control prices.

In order to strengthen the Government's purchasing power it is necessary that the President shall be enabled to proclaim maximum prices. In order, however, that such action shall be taken wisely it is advisable that an advisory board be created capable of collecting information on which to base such control of production, involving interference with the normal operation of the laws of supply and demand. Mining cannot respond immediately to an increased demand, but it can be crippled suddenly by unwise restrictions; therefore any administrative control required for the War must be exercised judiciously. At first the Government endeavored to assist importation of war minerals, thereby discouraging the development of domestic deposits. The shortage of ships stopped that abruptly and it became evident to everybody that this country had to make intensive effort to find every war mineral within its own borders or in the adjacent friendly territory of Canada. In order to encourage private initiative in the exploration and exploitation of the necessary minerals, it is essential that the Government state its requirements, announce its policy in regard to importation, and guarantee a minimum, as well as a maximum, price over a definite period long enough to justify systematic search and development of mineral deposits. Capital will not be induced to take the risk inseparable from mining adventure unless the basic uncertainties of the market are removed or lessened. Any steps in this direction, in order to be taken intelligently, should be guided by an agency exercising control over the mineral industry of the whole country. It is true we have the Geological Survey and the Bureau of Mines, but neither of these departments has the machinery adequate for the purpose. Such machinery can be made out of the War Minerals Committee, which has already demonstrated its energy and good sense. The Committee includes worthy representatives of both the Geological Survey and the Bureau of Mines, and it can be assumed with confidence that anything that the Committee does will be done with the willing aid of the two existing branches of administration. The head of the Committee, most appropriately, is a mining engineer of wide experience. So a good start has been made. In order to proceed on broader lines and in a more systematic manner, it is expected that provision will be made by Congress for the funds needed to purchase surplus production during a definite period; also that a clause in the bill will adjust the prices of imports after such prices have been established, otherwise the liability of the Government may be unduly increased by its obligation to purchase at guaranteed minimum prices. In order to check profiteering and to protect the miners themselves, it will be necessary to discipline the smelting and refining companies, which, in return for a stable market for their products, will be prevented from imposing unfair contracts on the mineral producers. Any reserves of stock will be put under the control of the Government, in the national interest, and to check speculation or manipulation within the limitation of the minimum and maximum prices. Another

clause will protect the producer by giving the President the power to control the cost of supplies entering into production. Thus, it will be seen, a radical scheme of legislation has been devised to meet the abnormal conditions created by the War. We feel confident that it will be accepted in good spirit as a means to a great end, namely, the waging of war to a victorious peace. Interference with industry is annoying, if casual or unnecessary; regulation of industry in time of war is necessary; we are facing a crisis that justifies unusual measures and we feel confident that all those taking part in mining will accept loyally any enactment that will conduce to national efficiency.

---

## Retrospect

---

The end of another year finds most of us serious, if not anxious. We are living in the midst of events that eclipse the importance of the individual experience. Our thoughts are projected continually beyond the narrow horizon of the individual life to that of the nation and of the world. We have been shaken out of our ordinary petty detachment into an awakened interest in the big things of existence. Many of our hopes and illusions have been shattered. The optimism that had led us to imagine that the jungle period of human evolution has passed forever, the belief that the ape and tiger in man had died with the reading of books has been falsified, the fond expectation that intellectual endowment would terminate savagery on land and sea has proved a delusion. We face a resurgence of brutishness, the appeal to physical strength, and the decision of an ungenerous and unchivalrous mode of fighting. In these winter days the outlook is obscure. The year 1917 had opened cheerfully; in the spring a new democracy came into being out of the ashes of a revolution; we hailed Russia as a comrade in the march of political progress. That hope has proved a Dead Sea apple. The destiny of Russia has passed into the hands of a group of crazy criminals; she has played the poltroon and the imbecile, yielding to cowardice and corruption her virility as a nation and her self-respect as a people. Russia has proved a quitter. If a people gets the kind of government it deserves, then Russia deserves her Germanized I. W. Ws to rule her henceforth. To us, who have known the Russians, their kindly character, their dogged courage, and the keen intelligence of their constitutional reformers, the debacle is a tragedy without mitigation. The Italian reverse is another lamentable event. Undoubtedly the sudden defeat on the Isonzo was due to treachery, to a refusal to fight on the part of those defending the extreme left flank. Poisoned by German propaganda they gave an opening through which the invader forced his way so promptly as to turn the whole battle-front and compel a disastrous retreat. That is now in the record of 1917; so also is the greater event of American participation, an event that goes far to compensate for the Russian collapse. But with the realiza-

tion of the great service already done by the United States in heartening the cause of right there comes an appreciation of the fact that it was done so late as to endanger the result of the War\*and to prolong it by at least two years. The regret that our entry into the conflict should have been delayed is hardly softened by the conviction, which we share, that the United States took action as soon as her people were ready for it, and that earlier interference would have found the President at the head of a distracted people. As we entered late so the greater is the effort that we must now make to bring the War to a decision, the only decision that will allow the unhindered development of liberal ideas and the continued progress of representative government in our own country and in the world at large. We care greatly for the ideals of political freedom, but another feature of the War forces itself upon our attention at this season of supposed peace and goodwill. Increasingly we who are detached by distance from the scenes of carnage and destruction in Europe are coming to understand the blistering pain that afflicts those overwhelmed by the great calamity. This year has seen a splendid awakening of sympathy with the victims of the special frightfulness unloosed by the Huns and of the manifold horrors inseparable from any war. Not only has money in increasing amount gone forward for the alleviation of that suffering, but even those heretofore heedless of the misery across the Atlantic have begun to feel the pathos of it all and the pressing need for doing what is humanly possible to mitigate the fell consequence of invasion and conquest by the beast with the brains of an engineer. We have traveled a long way since our last year's end; as a people we have committed ourselves to the greatest enterprise in which this young republic has ever taken a hand; we have awakened to our real part in the comity of nations; we are about to prove our manhood. Therefore we face 1918 sadly, soberly, but firmly, strong in the purpose to see it through.

## Perils of Inflation

Some years ago the Chinese revolutionary committee in San Francisco offered for sale an issue of paper money on behalf of the party seeking to supplant the dynasty of the yellow dragon with a democracy. At that particular moment there was no democratic Chinese government in existence; there was only the hope of one; so the committee offered the nominal equivalent of 10-dollar bills for five cents. The revolution succeeded and those who had gambled on the Chinese insurrection through the purchase of these bills reaped a handsome reward. That was fiat money, looked at from an end that is not often possible, and leading to a result that is even less frequently realized. No better example could be found to illuminate the fact that beneath fiat money rests nothing tangible. It is national pride that has made so many people in America at so many different times advocate currency inflation. The Government

seems so big, so powerful, so representative of the opulence of a vast productive area, that the national credit appears illimitable. It is difficult for men whose financial experience has not exceeded the simple transactions of buying and selling commodities to comprehend the delicacy of the mechanism of credit in modern industrial life, and people with this simple experience constitute the great majority of the population. They cannot see why the Government might not issue billions of greenbacks to pay for war-supplies as well as to borrow treasury-bills from the people in exchange for another promise to pay in the form of a bond. Mr. Vanderlip has been forced to come to the rescue, and he is expounding the doctrines of sound finance in the Middle West in order to nip the growing heresy in the bud, when, as a matter of fact, his services are urgently needed in Washington for other purposes. Nevertheless the fiat-money craze is a disease so perilous that a prophylactic must be applied instantly; it is a disease as dangerous as typhus; it floats in the air and inoculates the passers-by, once it gets going; no more insidious and damaging germ than this could the Teutons spread throughout the country; it is worse than tetanus or anthrax, because our financial structure would crumble should the greenback fallacy get itself written into law, and the result would be universal distress and suffering. Gold would continue the actual gauge of value, and paper the measure of timid and declining faith. It would not take long, on that basis, before a five-dollar pair of shoes would sell for a hundred paper dollars. The movement of commerce would be blocked by insistence on contracts for payment in gold, while no bank would dare to let the gold escape from its vaults. The advantage of the bond is that the Government defers the date of redemption; it shifts the time for payment to a coming generation, and has to meet no more than current interest. The treasury-note, on the other hand, is a promise to pay on demand. What is it that the Government promises to pay? It is gold! Unless there is a reasonable proportion of gold in the vaults to redeem the issue on the demand of doubting Thomases it will not take long for the fiat-money enthusiasts to realize as keenly as the bankers that the Government cannot pay and that the paper is worthless for all present needs. The end of inflation is the explosion of credit. In the case of China the revolutionary paper grew in value because the revolutionists got possession of the solid metallic resources of the country in time to save the situation. In Mexico the grafters made off with the gold, while the people were forced at the muzzle of the rifle to accept the paper money in exchange for commodities and labor, and in the end, in order to extinguish the last trace of the obligation, the Government decreed that, on the payment of taxes, which were collectible in gold, an additional sum, of an equal face-value, must be paid in the fiat money. Mexico furnishes many instructive lessons in the things to avoid in politics and infinance, yet even Carranza, after sneaking from the duty of redeeming his convenient revolutionary currency, has planted the country squarely on a hard-money basis.

# DISCUSSION

## Physics of Flotation

The Editor:

Sir—On page 535, *Trans. A. I. M. E.*, Vol. LV, R. J. Anderson, in summarizing the electrolytic and electrostatic phenomena of flotation, states that “bubbles in flotation are simply air-spaces, contained by a mantle of oil or of water and there is therefore nothing within to bear the charge. In case it could carry a charge, which would only be possible by the presence of contained ionized gases or water-vapor, the charge would be speedily dissipated by contact with the interfacial boundary.” He then refers to Fahrenwald’s article, ‘The Electro-statics of Flotation,’ *M. & S. P.*, Vol. III, No. II, page 375 (March 11, 1917). He does not refer to James A. Block’s article criticizing certain statements of Mr. Fahrenwald. This article is in the *M. & S. P.* of June 10, 1916.

O. C. Ralston, in the discussion of Mr. Anderson’s paper, brought out some other points of interest, but also stated that “Fahrenwald’s objections to this theory are sound.” In the last paragraph of Mr. Ralston’s discussion, on page 546, he makes this excellent remark: “Too many have been willing to contribute thoughts to the technical press and too few have busied themselves with experimental measurements to prove the theories proposed.”

I therefore take great pleasure in enclosing a copy of some paragraphs from Sir J. J. Thomson’s ‘Discharge of Electricity Through Gases’ (1898). He made a thorough investigation of the electrification of gases over twenty years ago. In all the literature that has been published on flotation, I have yet to see his researches quoted. L. S. Deitz Jr., now with the Bureau of Mines at Cornell, called my attention to these researches, soon after my articles in 1915 were written.

THOS. M. BAINS JR.

Minneapolis, Minn., November 2.

From J. J. Thomson’s ‘Discharge of Electricity Through Gases.’

### COMMUNICATION OF A CHARGE OF ELECTRICITY TO A GAS

One of the most striking phenomena connected with the electrical properties of gases is the difficulty of directly communicating a charge of electricity to a gas in its normal condition. A very simple instance will suffice to show this: let us take the case of a charged metal plate which is insulated so well that there is no leakage of electricity across its supports; let this plate be in

contact with the air or any other gas at a moderate temperature and let it be screened off from ultra-violet light and Röntgen rays, then the evidence of the best experiments we have proves that under these conditions the plate will suffer absolutely no loss of charge, provided the surface density of its electrification is less than a certain value. Thus, though myriads of molecules of the gas strike against the charged surface, they rebound from it without any electrification. To fully appreciate the significance of this result, we must remember the very large charges that can be carried by the gas under other conditions. The phenomena of electrolysis show that the charge on each unit surface of the plate could be carried thousands of millions of times over by a cubic centimetre of hydrogen at normal pressure and temperature. We must, I think, conclude that the inability of a gas (which when in a certain state has such an enormous capacity for carrying electricity) to take up when in its normal condition any of the charge of electricity from a body against which it strikes is very significant and suggestive.

Another fact which exhibits in perhaps even a more striking way the inability of the molecules of a gas to take up an electric charge is that the vapor arising from an electrified liquid is quite free from any charge of electricity. \* \* \* In these experiments the molecules of the unelectrified vapor came from or through an electrified surface and the conditions here seem such that if a molecule could ever get electrified by contact, it would do so in these experiments. Thus we see that when an electrified liquid evaporates the electrified particles are left behind, just as the salt in a salt solution is left behind on evaporation.

### ELECTRIFICATION OF GAS BY CHEMICAL MEANS

Chemical action is so frequently attended by electrical separation that we might expect that the most likely way to electrify a gas would be to make it one of the parties in the chemical reaction. Examples of electrification, apparently in a gas, produced by this method have been known for a long time, though it is only in recent years that experiments have been made to show that the electrification in these cases is not, in all cases, carried by dust which may either be present in the gas to begin with, or produced by the chemical reaction itself. One of the earliest-known cases of electrification produced in a gas by chemical action is that of the combustion of carbon. Pouillet found that when a carbon cylinder was being burnt, the cylinder was negatively electrified, while there was positive electrification in the gas over

the cylinder. Lavoisier and Laplace showed that the same effect takes place with glowing coal. Reiss proved that there was positive electricity in the air near a glowing platinum spiral. Pouillet found that when a jet of hydrogen was burnt in the air there was a negative electrification in the unburnt hydrogen of the jet. Another case was discovered by Lavoisier and Laplace, who found that when hydrogen is rapidly liberated by the action of sulphuric acid on iron, a strong positive electrification comes off. This, with other cases of electrification by chemical means, was investigated by Mr. Enright. As a good deal of spray is produced by the bubbling of the hydrogen through the sulphuric acid, it has been suggested that the spray and not the gas may in this case be the carrier of the electrification. To test this point, Mr. Townsend recently made in the Cavendish laboratory a series of experiments on the electrification produced when a gas is liberated by chemical action. He found that when the hydrogen produced by the action of strong sulphuric acid on iron or zinc was passed through tubes fitted with plugs of tightly packed glass wool it retained after its passage through these plugs a strong positive electrification, thus showing that no ordinary spray could be the carrier of the electrification.

Using an open beaker, Mr. Townsend found that when the mixture of the sulphuric acid and iron was heated to about 94° C., there was at first strong positive electrification at the mouth of the beaker when the chemical action was very vigorous and the gas was coming off with great rapidity. But as the temperature fell and the rate of evolution of hydrogen diminished, the positive electrification diminished, and finally changed to negative. It was found, however, that the negative electrification, unlike the positive, was completely stopped not only by a plug of glass wool, but even by a layer of wire gauze. This seems to indicate that the negative electrification is carried by coarse spray, while the positive on the hydrogen, or at any rate on much smaller carriers. If there is positive electrification in the hydrogen, there must be an equal quantity of negative in the sulphuric acid; if this is dashed into spray, the spray will be negatively charged. The experiments indicate that when the gas is not coming off very vigorously, the negative electrification carried from the vessel exceeds the positive carried off by the gas; while when the gas comes off with great rapidity, the positive electrification carried by it far exceeds the negative carried by the spray. Mr. Townsend investigated several other cases by electrification produced when a gas is liberated by chemical means. He found that when chlorine was liberated by the action of hydrochloric acid on manganese di-oxide, the chlorine had a strong positive electrification, and that when potassium permanganate was heated, there was positive electrification in the oxygen evolved.

#### ELECTRIFICATION OF GASES LIBERATED BY ELECTROLYSIS

Mr. Townsend has also found that when a strong current is sent through a solution of sulphuric acid, so that there is copious liberation of hydrogen at one terminal

and of oxygen at the other, there is positive electrification in the hydrogen, while the oxygen is either apparently unelectrified, or has a small positive charge. It is perhaps to the point to mention that in this case the oxygen is liberated by a secondary process; the negative ion is  $\text{SO}_4$  and the oxygen is liberated by the chemical action of this ion on the water. The positive electrification in the hydrogen is very much influenced by temperature. At the ordinary temperature of the laboratory there is very little electrification; when, however, the temperature is raised to 40 or 50° C., the electrification is very strong. When a solution of caustic potash is electrolyzed, there is, on the other hand, very little electrification in the hydrogen while the oxygen is negatively electrified, though the amount of this electrification is not nearly so large as that on the hydrogen in the preceding experiment. In this case the hydrogen is liberated by secondary chemical action and the great diminution in its electrification as compared with the previous case seems to show that a gas is more likely to be electrified from electrolysis when it forms one of the ions than when liberated by secondary chemical action. The amount of electrification in the oxygen rapidly increases with the temperature. If oil is added to the caustic potash solution, the sign of the electrification in the oxygen changes and the oxygen is positively instead of negatively electrified. The nature of the electrodes has a considerable influence on the amount of electrification which comes off with the gas.

#### ELECTRIFICATION BY THE SPLASHING OF LIQUIDS

One of the most effectual ways of charging a gas with electricity is by means of the splashing of liquids. It has been long known that there was something anomalous in the condition of atmospheric electricity at the feet of waterfalls, where the water fell upon rocks and broke into spray. Lenard investigated the subject with great thoroughness, and found that when a drop of water splashed against a metal plate [note that is what happens in the M. S. machines] a positive charge went to the water, while there was negative electrification in the surrounding air. This electrical separation is even more marked in the case of mercury than in that of water. A very simple way of showing the effect is to shake some mercury up vigorously in a bottle and then draw off the air. This will be found to have a negative charge; this charge is carried neither by dust nor by spray, for it will remain after the air has been sucked through glass wool or even through a coarse porous plate. [Note that this may be applied to the Callow process.] Lord Kelvin has shown that the reciprocal process of bubbling air through water also gives rise to electrification, the air which has bubbled through the water being negatively electrified.

To investigate the laws of electrification produced by splashing, it is often more convenient to measure the positive charge on the drop rather than the negative charge in the air. This can be done conveniently by the arrangement represented in Fig. 1.

A known quantity of the liquid to be investigated is allowed to fall through the funnel *A* and falls on the metal plate and saucer *C*, which is carefully insulated and connected with one pair of quadrants of an electrometer. The blower sends a strong current of air from the neighborhood of the plate, so as to prevent the negative electrification in the air interfering with the indications of the electrometer. The deflection of the electrometer when a given quantity of liquid falls on the plate may be taken as an indication of the electrification produced by the splashing of the liquid. By aid of an instrument of this kind, we can investigate the circum-

Fig. 1.

stances which affect the electrification. This electrification is influenced to a remarkable extent by minute changes in the composition of the liquid. [Note this.]

Lenard found that the electrification in the air in the neighborhood of the splashing plate, which was very marked with the exceptionally pure water of Heidelberg, was almost insensible with the less pure water of Bonn, while the splashing of a weak salt solution electrified the air in the neighborhood positively instead of negatively as when water was pure. Thus, while the splashing of the rain electrifies the air negatively, the breaking of waves on the seashore electrifies it positively.

In some of the experiments which I made on this subject I found that the effects produced by exceedingly minute traces of some substances were most surprisingly large. Rosaniline, for example, is a substance which has very great coloring power, so much so, indeed, that the color imparted to a large volume of water by a small quantity of rosaniline is sometimes given as an instance of the extent to which matter can be subdivided; yet I found that the change produced in the electrification, due to the splashing of drops, was appreciable in a solution so weak as to show no trace of color. The effects of fluorescent solutions on the electrification of drops is especially great, but different kinds of solution act in different ways. Thus rosaniline and methyl violet reverse the effect, that is, they make the electrification on the drop negative in the air; while eosine and fluorescein, on the other hand, increase the normal effect, that is, they make the drop more strongly electrified positively than a drop of pure water, and produce a greater negative electrification in the air.

The electrical effects of weak solutions are much

greater than those of strong ones [Note this]; in fact, strong solutions of all substances tested gave little or no electrical effects by splashing. The effect produced by the addition of foreign substances to water may be represented by curves, in which the abscissae are proportional to the amount of the substance added to the water, and the ordinates to the electrification produced by splashing. We find that these curves are of three types, *a*, *b*, and *c*. Fig. 2.

Fig. 2.

Curves of type (*a*) represent the behavior of solutions of phenol, eosine, fluorescein, where the addition of a small quantity of the substance increases the electrical effect.

Curves of the type (*b*) represent the behavior of solutions of potassium permanganate, chromium dioxide, hydrogen peroxide, rosaniline and methyl violet; here the addition of the substance begins by diminishing the electrification and finally reverses it.

Curves of the type (*c*) represent the behavior of solutions of zinc chloride, hydrochloric acid, and hydriodic acids, and in fact of most inorganic salts and acids; here the addition of the substance produces a diminution but not a reversal of the electrification.

The addition of strong oxidizing agents to the water seems, on the whole, to tend to reverse the normal effect, that is, it tends to make the electrification in the air positive, while the addition of the reducing agents seems to increase the normal effect.

We find that the electrification is produced by splashing of drops of substances as unlike as paraffin-oil [note], water, and mercury.

#### ELECTRIFICATION OF A GAS BY THE AID OF THE RÖNTGEN RAY

Of all the methods by which we can put a gas into a state in which it can receive a charge of electricity, none is more remarkable than that of the Röntgen rays. These rays, when passed through a gas, turn it into a conductor and enable it to receive a charge of electricity and the gas retains its conductivity and its power of being charged for some time after the rays have ceased to pass through it. \* \* \* If the gas in its passage from the aluminum vessel to the tester was made to bubble through water, every trace of the conductivity seemed to disappear. The gas also lost its conductivity when forced through a plug of glass wool. \* \* \* The properties of gases electrified when under the influence of the Röntgen ray differ somewhat from those of gases electrified by other means. Thus the electrification in a gas electrified under the Röntgen rays cannot pass through glass wool or bubble through water. [This nullifies Mr. Fahrenwald's experiments, in M. & S. P., Feb. 26, 1916.] It thus resembles the conducting power conferred on the

gas by these rays. On the other hand, as we have seen when the electrification in the gas is by chemical means [or splashing of liquids], the electrification is able to pass through glass wool or *bubble through conducting liquids*. [Note this.]

## Do We Need Gold?

The Editor:

Sir—Under the above heading, in your issue of December 1, Mr. Lester S. Grant asks "Why is gold mining?" From the context of his letter it appears that he, with many others, wants to know if gold mining, and probably other industries not essential to war, should be continued under the present world crisis.

Above all else, if this nation is to take part in financing the Allies, as well as in manning and financing an army of its own, it is manifestly essential that every dollar of new wealth from Nature's storehouse, should be brought into requisition and added to the financial strength of the nation, by the enrichment of its citizenry. The funds raised come from the citizens, from the profits of their industry, either through the purchase of bonds or through taxation. Again, a natural resource of energy lies dormant in every individual, which can be brought out and converted into new wealth only by its expenditure upon raw material. Are the reasons against the present mining of gold so obvious? The labor employed in the industry might or might not ultimately find its way into other channels; in the meantime, contemplate the loss of wealth to those at present so employed, the loss of purchasing power of the labor with the infinite reaction on production in innumerable lines, the proportionate loss of earning power along these lines, the lowered assessable valuation and the loss of profit, and their consequently lowered bond-purchasing power, to say nothing of the dormant, unprofitable, and untaxable condition of the natural material resources so suspended, and that cannot aid in purchasing bonds. As to the consumption of supplies, powder, machinery, foods—these operatives must live, must eat, must clothe themselves, whether mining gold, or doing something else. The increased wealth makes possible, through the expenditure of but a small percentage of itself, the provision for this additional consumption. Is not this relatively small item justified in the greater good the added wealth will engender? Every added dollar of new wealth lessens the burden on the dollar in circulation; every dollar's worth of new enterprise, of taxable values, lessens the burden of taxation on established industries, and every dollar of new wealth strengthens the arm of Uncle Sam in his fight for liberty and freedom. What of the investor in and the operator of gold mines? He must, in these times of high prices for labor, for explosives, for cyanide, for machinery, be a patriot. If not, he will not stay in the game. His ounce of gold brings not one cent more than it did in the time of peace. As a business proposition, it were wise to shut-down. Will he? But, looking farther,

what can he do with his profits? Will not these compensate, in part at least, for the near-by loss in mining the gold? I believe, judiciously applied, the profits will compensate in full, while the patriotic side is not to be overlooked.

L. S. ROPES.

Helena, Montana, December 3.

## The Threat to Gold Mining

The Editor:

Sir—Your timely editorial on this subject strikes me as particularly worthy of commendation. It certainly seems most short-sighted to do anything, by governmental action, that would decrease the output of gold.

The statement, frequently made in irresponsible publications, that the United States "has all the gold in the world" does not tend to convince the more careful-thinking ones.

In the financial column of the 'Chronicle' this morning it is stated that the public debts of the six leading belligerent nations on January 1, 1917, amounted to \$71,372,000,000, and that the enormous total, on the coming New Year's day, with our United States debt added, "will probably pass the hundred-billion mark." While the argument is made in favor of the re-monetization of silver, it is surely a better argument in behalf of a more liberal treatment of the gold-mine operators. In fact, some governmental stimulation of the production of gold that could be brought about without interference with the production of the other metals would be the more rational course to pursue.

The argument was made, as long ago as the first of last April, that an ounce of gold was worth only \$12 to \$14 because of the decrease in its purchasing power. But, for that reason, should the hungry prospector and impecunious mine-owner be satisfied with an offer for his property, based on specious figures, thus made to the detriment of the yellow metal? Either one of two things: the value of an ounce of gold, above cited, is a case of mistaken judgment, on the part of those so asserting it, or they have an ulterior object in view.

Your question "are we to diminish the foundation of our financial security, at this time of world-crisis" is one that is quite likely to be answered in the near future, by a reversal of the idle talk of shutting-down the gold mines and a substitution of encouragement to the gold-mine operators, who have already suffered by the rise in cost of supplies and the increased scale of wages. If there is anything more fallacious than the attempt to prove that we cannot secure enough gold to pay the annual interest charge, I would like to know what it is.

Since 60% of the world's output of gold is produced under the British flag, and only 20% in the United States, it would seem a clear case of discrimination against ourselves, if now we were to enact any regulations which would still further restrict the production of gold in our country.

F. L. SIZER.

San Francisco, December 17.

ANCHORAGE, ALASKA

## The Government Railroad of Alaska

By THEODORE PILGER

Since the mining business furnishes more than a half of the total freight-tonnage of American railroads, it is altogether fitting that the first railroad to be owned and operated by the Government should be built to tap what is hoped may prove to be one of the greatest undeveloped mining regions of the North American continent. The vast store of wealth that the territory of Alaska has contributed to the nation entitles it to substantial consideration, which can best be put in practical form by providing Alaska with a proper system of transportation.

During the years 1902 and 1903 the Alaska Central Railroad Co. built its line north from Seward. This company, being inadequately financed, was unable to carry out its purpose and soon went into bankruptcy. At later periods the bondholders and successors in interest constructed 71 miles of standard-gauge railroad from Seward north to Kern creek. The interests backing the company at this time were also practically in control of the Matanuska coalfields. In 1906 the Roosevelt order withdrawing the coalfields of Alaska from entry removed the principal source of freight anticipated by the railroad-builders and as they were again in financial straits the idea of building an Alaskan railroad by private capital was finally decided to be impracticable.

Shortly afterward came the Ballinger-Pinchot controversy which frightened capital to such an extent that it soon became apparent that the only capitalist who would build an Alaskan railroad to develop the territory was Uncle Sam. The Government could afford to build a railroad, develop the territory, and wait for the returns on its investment, while the ordinary capitalist would demand dividends from the beginning of operations on the road. However, it might have been that

private capital would have entered into this work had special inducements been offered by the Government, in the way of land-grants, or a guarantee of bond-interest, but neither of these plans are in accord with the policy of the Administration.

It was at this time that the Guggenheims were planning to open their Kennecott mine in the upper Copper River basin by means of a railroad that would also tap the Bering River coalfield, where the Cunninghams had located large areas, and would have its terminal at Katalla bay, which is the nearest harbor to the coalfield. This plan was abandoned because of physical difficulties and also because of the withdrawal from entry of the Bering River coalfield. The Guggenheims then selected Cordova as their terminal port, built 191 miles of railroad from that town to the Kennecott copper mine, and called their railroad the Copper River & Northwestern Railroad.

The first serious agitation for a government-owned and government-operated railroad started in 1911, during the Taft administration, while Walter L. Fisher was Secretary of the Interior. He visited Alaska, and recommended that the coal-lands be leased, also that the Bering River and Matanuska Valley coals be tested by the Navy Department, and that a Government railroad be built from Seward to the Matanuska coalfield, should that coal prove satisfactory. In 1912, a commission, known as the Taft Commission, having examined all the feasible routes, recommended that the Government should build from the station of Chitina on the Copper River & Northwestern railroad to the town of Fairbanks in the interior.

With the Wilson administration came Franklin K.

Lane as Secretary of the Interior. Although he has never visited Alaska, he has taken a keen interest in the development of the territory. He personally pushed the Railroad Act, and the Coal Lands Leasing Act, both of which were passed in 1914. By the Railroad Act, the President of the United States is restricted to cause to be built not more than 1000 miles of railroad, and to expend not to exceed \$35,000,000 thereon. President Wilson created the Alaska Engineering Commission, composed of W. C. Edes, chairman, Fredrick Mears, and Thomas Riggs, Jr., members. These are railroad men of wide experience and capability, having been engaged in engineering and construction work all their lives. They have fully justified the President's choice.\*

This commission first made preliminary surveys of various proposed lines, and finally recommended the Seward-Broad Pass-Fairbanks route, which runs from Seward on the west shore of Resurrection bay, northward through the Kenai peninsula, thence westward along the north shore of Turnagain Arm, along the east shore of Knik Arm, across the Knik and Matanuska rivers, in a north-westerly direction through the Susitna valley, across Broad Pass, down the Nenana river, and up Gold stream to Fairbanks. It also recommended the route of a branch line, designated from a point two miles north from where the main line crosses the Matanuska river, running thence in an easterly direction into the Matanuska coalfield.

These recommendations having been adopted, the Commission then purchased the 71 miles of railroad from Seward to Kern creek for \$1,500,000, although over \$4,000,000 had been expended on this railroad by the original owners; and the 40 miles of narrow-gauge railroad known as the Tanana Valley Railroad was also purchased at a later date for the sum of \$300,000. This bit of railroad goes north from Fairbanks and acts as a feeder to the main line. The reasons for the choice of the Seward-Fairbanks route by the Alaska Engineering Commission was that the railroad could be constructed with the least expense, as there were no great obstacles to overcome, and it was believed that this route would aid the development of the greatest amount of resources with benefit to the greatest number of people.

Broad Pass is a comparatively low and wide crossing, and there are no large streams or big glaciers to traverse. While the cuts and fills in many places are quite heavy, the greatest problems of construction are the securing and distribution of materials in a country that has no industrial development. The distribution of material and supplies for the most part has to be done over the snow in the winter, except where the work can be reached by waterways.

Beginning at Seward, which has an open harbor the

year round, on Resurrection bay, the railroad passes near the placer mines on the Kenai river. There are several quartz mines at various points on the railroad side of the Kenai peninsula, and fairly well-developed placer and lode claims above Sunrise and Hope, two camps on the same peninsula. Passing near placers on Glacier creek, the railroad runs through the agricultural lands around the town of Anchorage that open out into the broad valleys of the Matanuska and Susitna rivers. On the upper Matanuska branch are the seams that, it is hoped, will develop into producers of Pacific Coast coal. The centre of this coal district is the new railroad town of Chickaloon.

Both the Matanuska and Susitna valleys have been eroded by glaciers, and the lower stretches of both are of the 'pot and kettle' topography common to glacially eroded valleys. This topography causes many lakes and swamps in the lowlands, and most of the profitable ranches in these valleys are situated on the benches above the flats. From these agricultural regions on both sides of the Susitna valley, reaching for about 200 miles, are many partly prospected mining districts, such as the Willow Creek district, Kashwitna Creek, Cache Creek, Montana Creek, Sunshine Creek, Yentna River, Talkeetna River, and the Broad Pass district. North of Broad Pass lies first the Nenana coalfield, which has great deposits of a high-grade lignite and farther north are the agricultural lands of the Tanana valley, which has been considerably developed to supply the markets of the interior. Many of the ranches in this region are well-equipped and have been farmed since 1905.

The main line of the railroad is 470 miles long; with the Matanuska branch it will cover a distance of a little more than 500 miles. Acting within the restrictions of the Alaska Railroad Bill, with regard to mileage, this will leave practically 500 miles of railroad that can be built in the territory without further legislation, provided that the total expenditure for the 1000 miles falls within the \$35,000,000 appropriation to which the bill restricts the President. A reconnaissance survey has been made by the Commission, from the point where the main line turns north in the Susitna valley, following the Yentna river, crossing the main Alaskan range, down into the Kuskokwim valley. This valley is widely known for its agricultural and mining possibilities. The original estimate of the cost of the first 500 miles of the railroad was about \$27,000,000, but the War has raised prices so greatly since the estimate was made that it will probably fall 25% short of the mark. This would run the cost of the authorized railroad now being built up to the total appropriation of \$35,000,000, leaving no funds for the branch lines.

All the departments of the Government are working in close harmony with the Alaskan Engineering Commission in an attempt to render the work most fruitful in its results. The Bureau of Mines has an experimental station at Fairbanks and the Department of Agriculture its experimental station at Matanuska. The Federal Road Commission, which is a branch of the War Depart-

\*Mr. Edes prior to his appointment had for many years been in the employ of the Southern Pacific Railway as location and construction engineer. Mr. Mears was formerly general superintendent and chief engineer of the Panama railroad under the supervision of Colonel Goethals, and Mr. Riggs was formerly in charge of the Alaska Boundary Survey.

MAP OF CENTRAL ALASKA, SHOWING THE LINE OF THE GOVERNMENT RAILROAD

ment, is building good wagon-roads from the railroad at many points so that every possible inducement may be given to the development of tributary industries. The Geological Survey is pushing examinations and issuing reports on many new mining districts along the route. The Alaskan Engineering Commission has established a Telephone and Telegraph Department to handle the business along the line of the railroad. It appears that if some department of the Government would cover the territory lying away from the railroad with telephone lines so that dependable methods of communication could be had at all seasons it would do much for the development of the region.

The most difficult work has been in rock for about 30 miles along the north side of Turnagain Arm. Here the cost will be as much as \$100,000 per mile for the grading and bridging alone. This should be completed by the spring of 1918, and the line completed through from Seward early in the summer. Some difficulty is being experienced in crossing the large terminal moraine below Spencer glacier on the Kenai peninsula, but it is not regarded as serious. The Commission has purchased a large amount of equipment, which it will have on its hands when this road is completed, and it is believed that it will be the policy of the Government to build railroad-feeders to the main line from both the east and the west to furnish sufficient tonnage to render the road profitable. No part of the railroad is expected to be endangered by snow-slides, although it is probable that there will be some trouble from the deep snows in the Susitna valley and between Turnagain Arm and Seward. Many snow-sheds will undoubtedly have to be built.

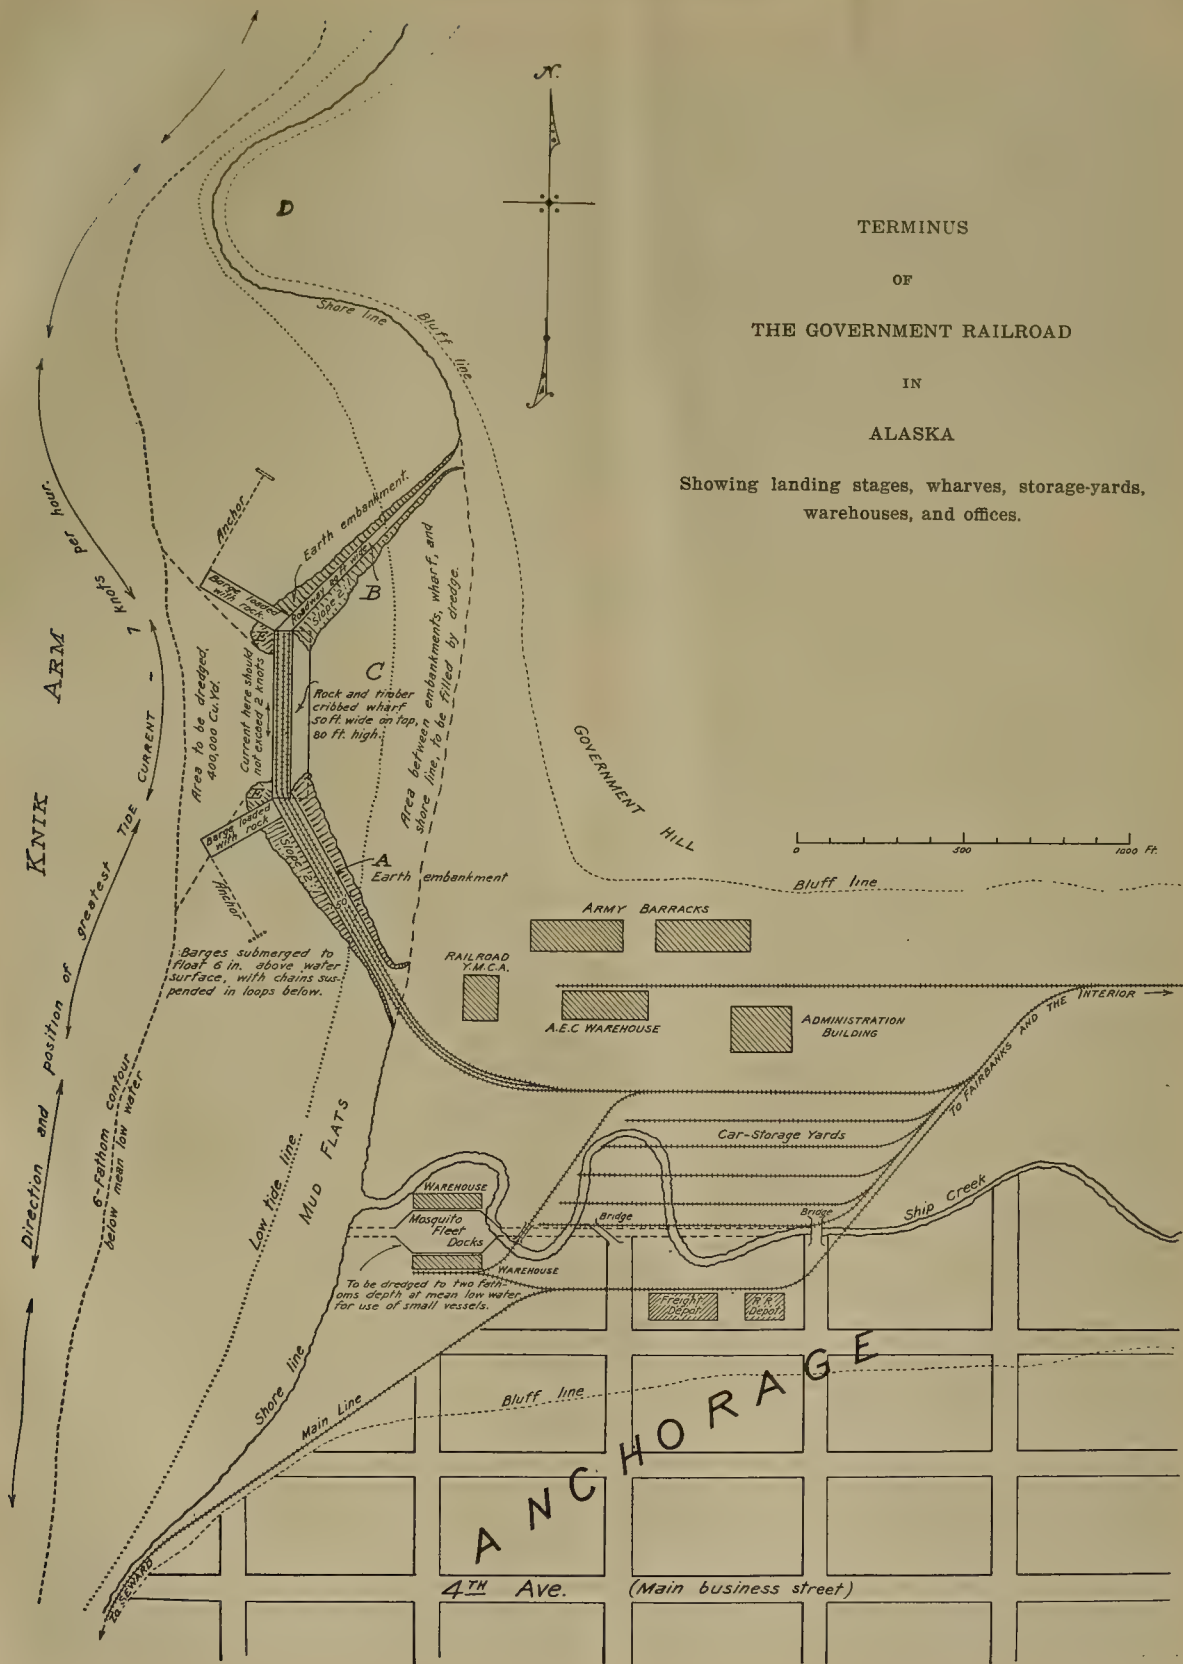

The railroad rates now in force are based on a doubling of the Western States Classification; thus passengers pay 6c. per mile, as against 12c. per mile over the Copper River & Northwestern. At the time that the railroad was before Congress, another bill was introduced to establish a steamship line from Seattle to Alaskan ports, to operate in conjunction with the railroad. This bill was rejected but it yet may be found that in order to develop Alaska rapidly, the Government will be obliged to go further than merely to build railroads. The freight-rates at present prevailing from Seattle to Anchorage on the average class of supplies are about \$20 per ton, while the U. S. transport 'Crook,' which brings up supplies and handles passengers for the A. E. C., lands freight at Anchorage for from \$8 to \$9 per ton. Potatoes when sacked, 100 lb. per sack, will average 3 cu. ft. in volume. The base rate for potatoes is \$14.50 per ton by volume. It being to the advantage of the steamship companies to charge by volume rather than by weight, the \$14.50 rate would apply for 1335 lb. of potatoes instead of 2000 lb. When wharfage is added, the charges for potatoes laid on the dock is \$30 per ton by weight. The first-class passenger fare on the steamship lines is \$60, while the 'Crook' brings its people in for \$30. If an employee of the Commission works three months for it, he will be taken outside for \$15; and

should he work two years for the Commission, he and his entire family will be taken outside and brought in again gratis. Some of the freight for the A. E. C. is brought from Seattle in barges towed by tugs, and but little business is given by the Commission to either the Alaska Steamship Co. or the Pacific Steamship Co., owned respectively by the American Smelting & Refining Co., and the D. C. Jackling interests. The Federal Shipping Board controls these freight-rates but it seems to be deaf to the appeals of Alaskans for relief from such exploitation.

Wages are good; every employee works an 8-hour day and receives time-and-a-half for over time. Ordinary crafts such as machinists, blacksmiths, and electricians receive \$6 per day while their helpers receive \$4.80. Train-men receive from \$150 to \$210 per month. At any place where board is furnished by the A. E. C. the charge is \$1.25 per day. Civil service rules do not apply. Authority is passed from the three members of the Commission, who have charge of the three divisions, respectively, to the heads of the departments, thence to the lower divisions of the departments, and from these in turn to bosses and to the laborers. Each official handles the men under his control with absolute authority with regard to hiring, discharging, and ordering. There is no central point where men are hired or discharged, the men being directly responsible to their immediate superior. An employment office at Anchorage supplies men to the various outlying points, but this office acts more as a registration headquarters for laborers than as a hiring agency. The main portion of the grade is being constructed by small contractors called 'station-men', using hand-work and push-cars. The smaller portions of the road that are being constructed directly by the Commission are being graded by power-shovels and steam-trains. All bridges are constructed by day's pay directly under the authority of the Commission. In contrast to railroad-building in the States, it is noticeable that there are no large contractors, no large construction camps, and no really big piece of work going on at any one point. There is an absence of the general rush and driving work that marks railroad-building outside. This does not mean that efficient work is not being done, but that it is being done in an entirely different manner, and under entirely different circumstances, for an entirely different purpose, and with entirely different difficulties to overcome. The general Federal Compensation Act applies to all employees of the A. E. C., but so far no pension system has been established.

The entire system has been divided into the Anchorage, Fairbanks, and Seward divisions, which employ collectively about 4500 men. Of this number, 2900 are employed on the Anchorage division, about 900 on the Seward division, and about 700 on the Fairbanks division. Seward is considered the terminal of the railroad, and Anchorage the terminal of the Anchorage division, which is, however, the most important division of the three. At Anchorage the Government will attempt to solve the difficulties connected with the maintaining of

city with a population of between 6000 and 7000. It is only a little over two years old. One of its banks, which started with a capitalization of \$25,000, now has deposits of over \$750,000. It is a division point and the second ocean port for the Government railroad. It is certain to be the principal coal-freight terminal for nine months of the year, if not for twelve. The summers are mild and the winters are not severe; being farther back from the Pacific the average temperature is a few degrees lower, and the rain and snow-fall less than at Seward. The summer days never end. Only twilight intervenes between two warm mellow days, but the days of winter are correspondingly brief. It does not resemble any typical Alaskan town, and neither is it like a boom town of a new mining district in the States. The Government has a large and well-appointed hospital, and buildings for all the departments of the railroad's operations. There is a large post-office, a telephone, telegraph, and electric-light office, a fine Masonic temple, several churches, lodge quarters, Y. M. C. A., and club-rooms. It has the largest labor temple in Alaska, a good school, well graded streets, the thoroughfares having concrete and the side streets board walks. The sale of liquor is unlawful, but liberal allowances are made for private use, and it is a very wet 'dry' town. January 1918 will change this, however, for then all Alaska will come under prohibition. The town boasts a large number of pretty and substantial homes, including those built by the Government for its employees, having electric lights and modern sewerage. The surrounding country is remarkably beautiful. In the distance can be seen at all times the splendid stretch of the Alaskan range, and on clear days Mt. McKinley rears its snow-crowned head against the blue, 20,300 ft. high and 175 miles distant.

CANADIUM, a new metal, has been discovered in the Nelson mining district of British Columbia, and has been named for Canada. It is allied to the platinum group and occurs native in the form of grains and short crystalline rods and also as an alloy. Assays give three ounces or less per ton. Canadium has a brilliant lustre, and, like gold, silver, and platinum, does not oxidize when exposed to the air. It is softer than platinum, and its melting point is a great deal lower. The physical and chemical properties of the metal are to be studied at the chemical laboratory of the University of Glasgow.—'Daily Metal Reporter.'

TINNED copper is not superior in any way to tin-plate for roofing material and in view of its greater cost cannot compete with it. This has been shown by tests made by the Bureau of Mines. Tinned sheet copper is used for containing-vessels such as milk-cans and for fittings where corrosion is to be resisted. There seems to be no warrant for its use, and it is probable that such articles would be subject to pitting and corrosion of the same type as that shown in the tests if they were not worn out by abrasion before the corrosion takes place to any extent.

## Foundations for Small Gas-Engines

To obtain the highest efficiency an engine should have a firm heavy foundation. This will reduce wear and tear from vibration, and will result in prolonged and better service. Rigidity and durability in the foundation are best obtained through the use of concrete. It should be mixed in the proportion of 1 part portland cement, 3 parts clean well-graded sand, and 5 parts crushed stone or gravel. The use of accurate measuring-boxes is advisable. The sand should pass a  $\frac{1}{4}$ -in. mesh sieve, and the crushed stone or gravel should pass readily through a  $1\frac{1}{2}$ -in. opening. In no case should bank-run gravel be used without being screened. If the size of the engine warrants the use of a reinforced-concrete footing, a 1:2:4 mix should be used for the reinforced portion of the concrete. Sufficient water should be used to form a plastic mixture, but not enough to cause separation of the cement and aggregates when placed. After the position of the centre-line of the foundation has been determined, a pit two to four feet deep should be excavated, the same size as the footing. The concrete should be deposited to the depth determined in the plan. In order to key the engine foundation to the footing, stones three to four inches in diameter should be embedded in the portion of the footing under the engine so that they will protrude. A box-form eight inches larger in both length and width than the engine-base should be carefully set over the footing. The inside of the forms should be oiled to prevent the concrete from adhering. It is essential that the anchor-bolts for the engine be carefully spaced and so placed as to take care of any small variations in position. A templet should be used, also greased gas-pipes twice the diameter of the bolts. The purpose of the pipes is to provide for such slight adjustments of bolts as may be required. The anchor-bolts should be embedded in the concrete at least 18 in., and should be supplied with cast-iron washers at the lower ends. When the templet has been accurately set over the forms and the bolts so arranged that the tops are at a proper elevation, the concrete is deposited carefully and spaded into the form. The gas-pipes should be turned from time to time, thus preventing them from sticking to the concrete. Sticking may be prevented effectually by wrapping the pipe with oiled manila paper, taking care that it does not become torn while pouring the concrete. The concrete next to the form should be carefully spaded to prevent the formation of air-bubbles or pockets. Damp burlap should be placed over the form after the concrete is poured. This will ensure normal set. After 24 hours the form can be removed. The engine may be set and the bolts adjusted after 48 hours. Before the engine is set the gas-pipes should be removed, and when the engine is finally placed, the space around the bolts should be filled with 1:1 mortar. The engine should not be used until the concrete is at least two weeks old. If necessary to have an exhaust or drain-pipe, this may be set in the form before the concrete is deposited.

# The War Excess-Profit Tax

By PHILIP WISEMAN

**EXCESS PROFITS.** It is evident from the discussions in Congress and in the press that the intent under Title II was to levy a tax upon abnormal profits, due to war conditions. While the text of Title II makes no further reference to 'excess profits,' are not the title and the evident intent sufficient to justify the Treasury department in ruling that its application should be only to cases where abnormal profits have been secured?

If the taxes imposed under Section 201 had not been intended to be applied to abnormal taxes and were to be additional sur-taxes, there would have been no occasion for Title II, as additional sur-taxes would more properly have been added to Title I of the Act.

With this view of the meaning and intent of Title II and its schedules, the first thing necessary is to determine whether or not a corporation has earned a profit in excess of what it would have earned under pre-war conditions, and in case it has done so, whether the additional profit is the result merely of enlarged operations or is due to abnormal prices received for the output.

If the 1917 profit is not in excess of the pre-war profits, the schedules in Title II would not be used. If an excess profit is indicated, the next point to determine is whether the increased, or excess profit, is due to abnormal prices for the products disposed of or merely to the use of additional capital upon which there has been only the pre-war rate of return. If the latter should prove to be the case, the schedules of Title II would not apply. The important thing to be determined is whether or not a profit in excess of pre-war figures has been obtained, and how, and the question of invested capital should be only secondary.

**INVESTED CAPITAL.** This term in some instances may be interpreted fairly by considering only the cash that may have been put into the enterprise, but probably in the great majority of cases other factors should be taken into consideration. There is a recognized relation between earning capacity and market-value and possibly in most cases the market-value may fairly be taken as the 'invested capital.'

That a corporation may not have desired to realize upon an increase in the value of its property over and above the original cash investment (which realizable value may be fairly indicated by the market-value of its shares), should not operate against it in the levying of the excess-profit tax by requiring the company to consider its invested capital to be a less amount than the property is reasonably worth. The purchaser of such a property would be taxed, under the provisions of Title II, upon the basis of the amount paid for the property, and this would result in the purchaser paying a lower

tax than the selling company had been required to pay unless the latter had been permitted to consider the market-value of the property to be its invested capital. The mere transfer of the title of a property should not thus affect the taxes to be paid upon it.

For example: If one were to take up 320 acres of desert land and put water upon it at an expense of \$25 per acre, the invested capital (omitting the small price paid the Government for the land) would be \$8000. With water upon it, this land might be as fully productive as land for which \$200 per acre would readily be paid. The invested capital of the one who had paid \$200 per acre for 320 acres would be \$64,000, while under strict and literal interpretation the one who had had the enterprise, ability, and judgment to develop hitherto worthless land would be allowed only \$8000 as 'invested capital,' even though the improved land were readily salable for eight times that amount, and, assuming a net return of \$50 per acre, the excess-profit tax he would have to pay would be nearly three and a half times that which the purchaser at \$200 per acre would be required to pay. The injustice of such an interpretation of the term 'invested capital' in this or analogous cases seems obvious. The example cited applies with equal force to many industries, and particularly to oil and mining companies. Anyone developing the natural resources of the country is deserving of encouragement and should not be required to pay taxes at what amounts to a higher rate than would be paid by the one who purchases at its market-value property already producing or ready for production.

The Treasury department has recognized the fairness of taking the market-value of the property, rather than the actual cash investment, in the levying of the excise tax, and the same logic should apply, in equity, and the value of the property, as nearly as it can be determined, be considered a necessary factor in arriving at the amount of the invested capital.

The conduct of the business of a corporation may result in an increase of its assets. Its net assets are its invested capital, and the amount of its net assets is the principal factor in the determination by investors of the market-value of its shares.

The invested capital of a bank, or a similar institution, may be wholly cash, or cash and the amount it may have invested in bonds, securities, and loans. The invested capital would, of course, include its accumulated surplus. In other lines of business activity, the invested capital may be represented, in whole or in part, by the accumulation of some commodity, and its selling price determines the invested capital of the enterprise.

In the case of mining properties, the value of the ore-reserve would properly be considered as being a part of the invested capital. This would be the case even though the ore-reserves were regarded as surplus. 'Surplus' is usually thought of in terms of cash, but it may be in any form of property. Even in banking, where the exploitation of cash as a commodity is the principal purpose of the business, the surplus accumulated is not necessarily represented by cash, but may be represented entirely by the value of bonds and securities purchased and loans made. A great deal of the perplexity regarding the interpretation and possible application of Title II is due to the injection of the words 'invested capital.' As the intent of the Act, as was clearly indicated by the discussions in Congress, was to levy additional taxes upon abnormal profits realized, due to war conditions, in excess of pre-war profits, the amount of invested capital is in no sense a factor, excepting in cases where it is necessary to determine whether the excess profits realized are due to abnormal prices received for the output or to the use of additional capital upon which only the pre-war rate of profit was received.

**PAR VALUE OF STOCKS.** In Title II there are several references to the par value of stocks and no provision seems to have been made for valuing stocks at an amount in excess of par. In many instances the adherence to the view that stocks should not be considered as having a value in excess of par would cause great injustice in the levying of this tax, particularly upon oil and mining companies. With a bank, or similar institution, there is a quite direct relation between actual value and par value, for cash is the commodity dealt in, and, at the time of organization, bank stock is usually sold at par, though if it is desired to show a surplus, the stock may be sold above par. After a bank has been engaged in business for some time any further issue of stock it may make may be at a value considerably in excess of par, because the condition and extent of the bank's business justified it. On the other hand, the stock of a bank, for which par may have been paid, may have a value far below par, owing to unwise management. Therefore it has become an axiom with the intelligent investor that he must consider the actual value of the property behind the stock and not the par value ascribed to the stocks. It is the recognition of this fact that has caused many companies to organize in recent years without par value to their shares. While the par value of a stock is unimportant, it is important for the shareholders to know the number of shares issued, because the extent of his ownership in the property is thus defined. With conservative mining companies it has been the practice to capitalize at relatively low figures, and such conservatism has had the commendation of banking institutions and investors. The result is that with a satisfactory development a property may have a market-value far in excess of its capitalization. If a company is to be penalized for conservatism, it is equivalent to placing a premium on gross over-capitalization and the 'watering' of stock, practices that are frowned upon. If a stock is

purchased at its market-price because of the known value of the property, and that price is in excess of the par value, an injustice is done to the holder of the stock if the company is not permitted to value at market-price any shares it may issue. The ultimate value of a mining property is rarely even approximately correctly estimated in the early stages of its development and only in exceptional cases is it deemed advisable to keep more than two or three years' supply of ore ready for extraction; consequently, any disturbance in the ratio between the increase of ore-reserves and their depletion affects the price of the stock.

**DEPLETION.** The net proceeds from the operation of a mining property do not represent the profit, though often so regarded. In the net proceeds of operation are included return of capital, interest on investment, and the profit. Just what percentage of the net proceeds each represents is difficult to determine. With the uncertainties attending further development, it is only equitable that a liberal deduction for depletion should be made from the net proceeds. Some mining properties have ore so low in grade that the success of the enterprise is dependent upon the assurance of an enormous tonnage prior to the installation of reduction plants. In such cases, it is possible to figure a much lower rate of depletion than where the ore-reserve is only a few years in advance of the production rate and the possibility of maintaining the ore-reserve is questionable.

**GOLD-MINING COMPANIES.** The interpretation and application of the provisions of Title II to gold-mining companies is a matter of much concern to such companies. These are required to pay an income tax, but they should not be obliged to pay an excess-profit tax under Title II, for the reason that they obviously cannot gain an 'excess profit.' Gold is the basis of all values. The Government, in establishing our financial system on a gold basis, fixed the price of gold at \$20.67 per ounce, and thus it has become the measure of value for all other commodities. In the case of copper, zinc, lead, and other base metals there has been a great appreciation owing to war conditions, but gold-mining companies receive no more for their output than before the War, while, on the other hand, it has been necessary for them to pay greatly increased prices for labor, material, and supplies, so that in effect, gold has depreciated in value because its purchasing power is less, with the result that gold-mining companies have a less income under existing conditions than they would have had under pre-war conditions. The purchasers of stock in such companies pay the market-price for their stock, and the market-price is considered a fair gauge of the value of the property. If the schedules of Title II are levied against gold-mining companies, it would, for many of the shareholders, amount virtually to confiscation. The individual income-tax schedules under Title I very adequately take care of any large incomes received from gold mining as well as other sources.

Mining is justly regarded as a hazardous enterprise, and as the value of a mining property is reduced by

each ton of ore removed from it, it is difficult to determine just what proportion of a year's production is return of capital, interest on investment, or profit. If the taxes to be imposed upon gold-mining companies practically amount to confiscation, it would seem there was considerable justification in the demand of stockholders that the gold properties cease production so long as the excess-profit tax schedules of Title II are levied.

Considering that gold is the basis of our financial structure, it would seem that the production of gold should be encouraged, rather than discouraged. Every dollar's worth of gold added to the country's supply permits a maximum banking credit of about 20 dollars. Only a few months ago, there was considerable alarm because a comparatively small amount of gold had to be shipped from the United States to other countries. There were suggestions recently that all gold coin should be withdrawn from circulation in order to strengthen our financial position.

The directors and stockholders of gold-mining companies have no desire to shirk the responsibility now resting upon every citizen, but it is desired to call attention to certain inequitable provisions of the War Revenue Act as it now stands, so that they may either be corrected by Congress, or interpreted equitably by the Treasury department, in case Congressional action is unnecessary.

On account of the many diverse businesses and industries in the country and the various manners in which they have originated and have been developed, it is exceedingly difficult to frame a law that will be sufficiently specific to cover equitably all the cases to come up for consideration. Therefore, any changes in the War Revenue Act should be with the idea of stating clearly in general terms the intent of the law, with such exceptions as a more thorough study of the Act would now suggest, and authorizing the Secretary of the Treasury to determine the equity in any cases submitted to him, rather than require him to adhere to a literal interpretation, which may be clearly inequitable. For example:

UNITED EASTERN MINING CO. This company was organized in 1913 with a capitalization of 1,500,000 shares of a par value of \$1. Its orebodies were developed rapidly and the stock soon had a market-value far in excess of par. Production did not commence until January 1917. As the output is gold, with an almost negligible amount of silver, there has been no abnormal or excess profit, because the price for gold has remained at \$20.67 per ounce, although in effect it is less, for its purchasing power has diminished owing to the rise in the price of labor and materials.

The net proceeds are actually less than they would have been under pre-war conditions. The purchase of another property was effected by the delivery of treasury stock. The market-value of this stock at the time was approximately five times par. It would have been perfectly feasible to have sold this stock for cash at the market-price and delivered the cash. The purchase for

the number of shares delivered was only possible because the shares had a market-value, legitimately based upon proved ore, of approximately five times the par value. Is it equitable that it should militate against the company because shares were delivered instead of the cash for which those shares could have been sold? This company, as a gold-producer, should not be required to pay an excess-profit tax, and in no event should it be penalized for delivering its shares instead of the cash that could have been realized from the sale of the shares.

The depletion of the ore-reserve is proceeding at a relatively rapid rate; therefore, a high rate for depletion should be allowed.

SUMMARY. The following suggestions are offered:

1. That the provisions under Title II be amended or interpreted in accordance with the discussions in Congress, so that it will clearly apply only to abnormal profits in excess of pre-war profits due to increased prices received for products.

2. That the provisions under Title II be amended by omitting 'invested capital' as a factor in determining excess profits, except in cases where the additional profit is due to the use of additional capital.

3. That if 'invested capital' be not omitted that it be interpreted to mean the fair market-value of a company's stock or its net assets.

4. That the provisions under Title II be amended so that the value of shares issued for property, etc., shall not be limited by the par value, but be taken at either the market-value of the shares or the market-value of the property for which the shares are exchanged.

5. That the provisions under Title II be amended to exempt gold-mining companies from its provisions until the Government authorizes a price in excess of \$20.67 per ounce.

6. That Title II be amended to permit mining companies (or companies with similar wasting assets) to deduct an equitable amount for depletion in arriving at net profits.

7. That the War Revenue Act be amended so that the Secretary of the Treasury will be empowered to determine the merits of cases arising under its provisions and adjust them equitably.

AN international monetary system based on silver as well as gold, to provide for the expanding credit of the world, due to war exigencies, is under consideration by the Treasury Department, in conjunction with allied and neutral governments. If the scheme is worked out along the line now being discussed, gold and silver would be put upon a ratio of coinage together forming the basis upon which the paper money of the United States and of the allied and neutral countries would be issued. In other words, bi-metallism would be restored in the money standard of the nation, but under such circumstances that the gold would not disappear from circulation, as would happen if the United States were to adopt it without such international agreement. France may view it kindly, but the attitude of Great Britain is doubtful.

## Pig-Iron From Scrap-Steel

The electric furnace has made possible what may be regarded as almost a revolution in the steel industry. It is the conversion of scrap-steel or iron back into pig-iron. What may be called 'synthetic pig-iron' is now a commercial product; in other words, the original constituents of pig-iron are being made to re-unite in the condition originally assumed. This unusual achievement is another evidence of the adaptability of electrical energy to the production of results impossible by any other means. The new process is being applied commercially in a large electric-steel plant in the eastern part of the United States, high-grade or low-phosphorus pig-iron being made directly from ordinary scrap-steel. Not only is pig-iron being produced in large quantities, but wash-metal and iron and steel-castings are made in the same furnaces. The pig-iron sells in the open market as a competitor with regular low-phosphorus blast-furnace iron, the wash-metal goes to crucible-steel makers, and the iron-castings are sold to near-by users, or else are used by the company in its rolling mill.

The idea is not new, but this is the first record of its commercial exploitation in the United States. Late in 1912, Horace W. Lash, of the Garrett-Cromwell Engineering Co., of Cleveland, organized a corporation for the purpose of converting scrap-steel and iron into pig-iron in an electric furnace on the Pacific Coast. Pig-iron being expensive in that part of the country, and the fact that it could be made by this process without the use of coke, charcoal, or coal, which are not cheaply available there, were the impelling reasons. It is not known that the company carried out its plans, but it is understood that Robert Trumbull, an engineer at one time identified with Heroult in his efforts to introduce his electric furnace in America, is now producing pig-iron from scrap in an electric furnace in Canada.

The Eastern concern that has been successfully operating, as stated above, is known as the Sweetser-Bainbridge Metal Alloy Corporation of Watervliet, New York. For several months it has been producing from a Ludlum electric furnace. About 50 tons per day is the present output from two 5-ton furnaces.

There is no secret about the process. It is made possible by the unusual metallurgical feats which the electric furnace can perform. The actual method used by the company is not revealed. In general, however, ordinary scrap-steel of any grade is introduced into the furnace cold. The process is basic. The material is melted and refined if necessary, depending on the quality of the scrap and the degree of refinement desired in the product. These considerations also influence the cost. After the desired refinement is reached, the slag is removed. The necessary amount of ferro-silicon and ferro-manganese is added to bring the iron to the composition desired and

then the carbon is added in the form of fine coke and this is easily absorbed by the hot metal. Five or six 5-ton heats per day in each of two 5-ton furnaces are being regularly produced by the above or a similar process. There is no difficulty in its execution and no question as to the quality of the products. In respect to sulphur and phosphorus, they equal if they do not surpass any blast-furnace or cupola product, as shown by the analyses that follow. Regulation of the temperature or the composition is apparently simple, and a range from high-grade low-phosphorus iron and wash-metal down to the high-phosphorus foundry and other irons is claimed to be possible, and it probably is. The graphitic-carbon content is regulated by the introduction of varying percentages of silicon. The manganese can be made anything desired and the total carbon is not difficult to regulate. The amount of phosphorus and sulphur is readily placed at almost any required percentage, depending on the composition of the scrap charged and the degree of refinement before conversion into pig-iron or iron-castings.

The commercial possibilities of the new process are shown, so far as the composition of the products is concerned, by the following analyses made in ordinary operation:

COMPOSITION OF PIG-IRON MADE FROM SCRAP-STEEL

	Sample No. 1, %	Sample No. 2, %	Sample No. 3, %
Total carbon .....	3.60	3.73	3.38
Manganese .....	0.41	0.35	0.31
Silicon .....	1.77	1.52	0.15
Sulphur .....	0.007	0.008	0.028
Phosphorus .....	0.019	0.030	0.032

The average phosphorus-content of the iron so far made has averaged 0.023%. The graphitic carbon can be whatever is desired, or as high as 3.50%, depending on the silicon content.

COMPOSITION OF WASH-METAL MADE FROM SCRAP-STEEL

	Sample No. 1, %	Sample No. 2, %
Total carbon .....	3.55	3.83
Graphitic carbon .....	none	none
Manganese .....	0.37	0.32
Silicon .....	0.20	0.14
Sulphur .....	0.020	0.012
Phosphorus .....	0.014	0.018

COMPOSITION OF CAST-IRON CASINGS MADE FROM SCRAP-STEEL

	Sample No. 1, %	Sample No. 2, %
Total carbon .....	3.36	3.63
Graphitic carbon .....	...	3.08
Manganese .....	0.36	0.31
Silicon .....	1.30	1.15
Sulphur .....	0.019	0.014
Phosphorus .....	0.024	0.018

AN ELECTRIC FURNACE ABOUT TO BE CHARGED WITH SCRAP-STEEL. A LIFTING-MAGNET IS DELIVERING THE SCRAP

FILES OF PIG-IRON MADE FROM SCRAP-STEEL AND THE MOLDS IN WHICH THE METAL RUNS FROM THE ELECTRIC FURNACE

These analyses show how varied compositions can be controlled. The low-silicon content of the wash-metal permits the carbon to remain almost entirely in the combined state.

The pig-iron is reported to be very tough and strong. As to cast-iron in the form of castings, the experience of the Ludlum Steel Co. is cited. Cast-iron wobblers, for use in the company's rolling mill, which were purchased in the open market, were breaking at the rate of 10 to 12 per day. Wobblers from iron made in the electric furnace have been in use for two or three months without a case of breakage. The company also made the breaking-boxes on the mill of electric cast-iron. These should break easily when performing their normal function, but when made of this iron they were found to be entirely too tough, and their section had to be reduced considerably. It is believed that some explanation for these qualities may be found in the crystalline structure of the iron as well as in its greater purity compared with cupola-iron, this being contrary to cupola-practice, in which the sulphur rises with each re-melting in the electric process. In making steel castings the conversion loss is put at 5%. The cost of production is one of the vital points. So long as low-phosphorus pig-iron is selling at its present war price there can be no question as to the liberal profits obtainable. Whether in normal times such a method of making this grade or any other grade of pig-iron or castings is economically possible depends on several factors. First among these are the consumption of electricity and the grade of scrap used. If a relatively pure scrap-steel is the starting point, practically no refinement is necessary, and the kilowatt-hour consumption is at a minimum. The converse is true if poorer scrap, requiring more refinement, is used. The matter of other materials and the question of labor and electrode-charges are fairly constant in all cases. Owing to the fact that the Sweetser-Bainbridge Co. has been operating this process only for a short time and under rather imperfect conditions, actual data as to the cost of production are not available. Extensive experiments are being made to determine costs under various conditions and in various stages of the process, and these will be known in the near future. It is the estimate of the metallurgists of the company that the kilowatt-hour consumption of electricity per ton of pig-iron produced can be brought below 400 kw-hr. depending upon transformer-capacity, grade of scrap used, and the product desired. Electrode consumption and refractory renewals, it is said, are low, even under the prevailing abnormal costs of these materials. One melter and four men on each shift of eight hours are employed to operate the two furnaces, which, in 24 hours, are reported to produce 5 tons each, or 50 tons in all. With cheaper iron and steel-scrap in normal times it is claimed that the total cost would be lower.

The furnace in which the foregoing products are being made has come to be known as the Ludlum. Besides the two now making pig-iron, there are two 10-ton furnaces producing high-grade special and tool-steels in the new

plant of the Ludlum Steel Co. This concern is a large producer of the new chromium permanent-magnet steel and it also makes chromium roller-bearing steels. There are two fields in which 'synthetic pig-iron' may play an important rôle. It is certainly practical and economical in districts where blast-furnace production is not possible as on the Pacific Coast. It is also likely that its purity and probably superior dynamic and static properties may make it a worthy competitor of charcoal-iron.

## Corrosion of Barbed Wire

As a result of complaints of the short life of fence wire made by users, some 15 years ago, the U. S. Department of Agriculture made an investigation with a view to improving its resisting qualities. Notwithstanding this, there is continuous complaint of the short life of wire procurable today, as compared to some of the older brands of wire, much of which is still in service. A study of the analyses of a number of fence wires that have been in use for a number of years shows that those best resisting atmospheric influences generally contained greater or less quantities of copper, the rust-resisting quality of the wire increasing directly with the copper content. Much of the bessemer steel made 20 to 30 years ago contained copper, while that of more recent manufacture contains but a trace. The reason for this is that metallurgists have objected, and many still do object, to the presence of copper in structural steel, claiming that it makes the metal red-short, so, to meet this objection, care has been taken recently to eliminate copper from manufactured bessemer steel, hence its poor rust-resisting qualities.

The rate of corrosion of fence wire varies with the location. Not only do climatic conditions and the presence of industrial corrosive gases in the atmosphere influence the speed of corrosion but the position of the wire on the fence; whether it be the top or bottom strand, whether shaded, covered by bush, or next to a post or tree, plays a by no means inconsiderable part in the rate of its corrosion. The bottom wire on a fence generally will be found in a better state of preservation than a top wire, and wires shaded by trees and shrubbery, curiously, are less prone to rust than those in the open. All this makes it exceedingly difficult to obtain trustworthy data. The ideal condition for a corrosion test would seem to be in a strand of barbed wire, made by twisting together two wires of different composition, but even here there is the danger of an electrolytic action being set up which might act prejudicially on the wire that, under ordinary conditions, would be the most rust-resisting. Experiments are being conducted at a number of our universities with the view to finding an alloy, that, while not materially increasing the cost of the steel, will make it more resistant against atmospheric influences. Some success has already been attained and it is to be hoped that before long users of wire fences will be provided with a more satisfactory material.

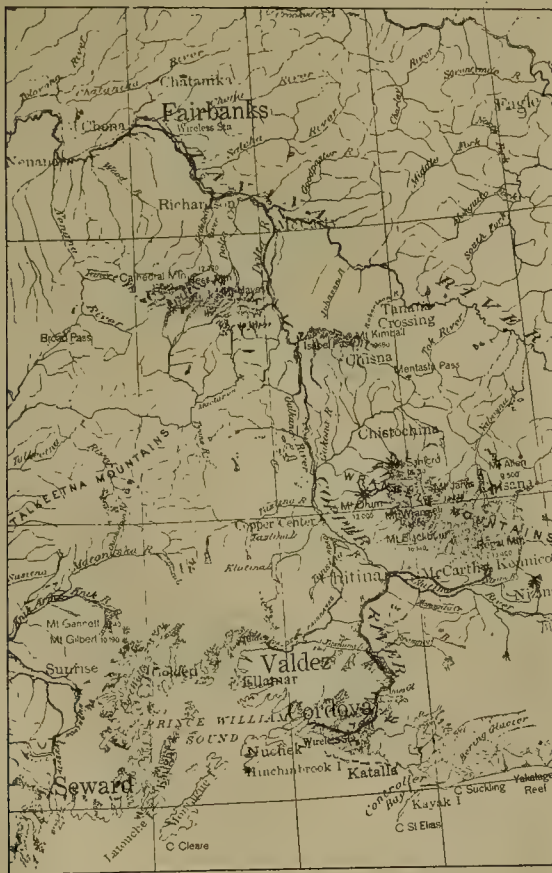

## CORDOVA, ALASKA

DEVELOPMENT IN THE COPPER RIVER DISTRICT.

The Kennecott Copper Co. overcame most of its labor troubles. The strike at Kennecott lasted about a month and at the present time the mine is operated full-handed. During the summer a new bunk-house was built; it has a capacity for 300 men, affords individual rooms, which are steam-heated, electric-lighted, clean, and well ventilated. A dining-room furnishing board at \$1.25 per day is included in the same build-

PART OF ALASKA, SHOWING POSITION OF COPPER RIVER

ing. With copper at 23¢ as set by the Government the miners are paid \$4.75 per day. The company has built a recreation hall, of frame construction, containing card-rooms, pool and billiard-rooms, reading-rooms, together with a moving-picture theatre which is open every Sunday night. The new Bonanza shaft, sunk on an incline of about 45° from the main-haulage adit, was completed to the 900-ft. level; a new electric hoist was installed and is now operating, using skips. The bunk-house at the mill has been enlarged to accommodate from 150

to 200 men, and a recreation hall, similar to the one at the mine, is available to the men. Two 250-hp. Erie City boilers, burning crude oil, and a 500-hp. steam-turbine will generate electric power for mine and mill.

The Mother Lode Copper Mines Co., of which James J. Godfrey is president, has spent the summer in making improvements. The company built about 15 miles of wagon-road from McCarthy, on the C. R. & N. W. R. R., to the mill on McCarthy creek. This 15 miles of automobile road has 16 bridges and two tunnels; it was constructed without Federal or Territorial aid of any kind, without even co-operation with any other mine-owners; it is, therefore, natural that the Mother Lode company should exact a toll. Motor-trucks were used for hauling during the summer, and it is thought they will serve in winter. Two months in the fall and two in the spring will probably be the only periods wherein motor-truck hauling will be impracticable. The timber for the bridges was brought from Puget Sound. Although there is a great quantity of good timber near Cordova, it is found cheaper to pay the freight and steamship rates from Seattle to McCarthy. The combined rate from Seattle to McCarthy is \$25 per M for 100,000-ft. lots, or over, and the freight-rate from Cordova to McCarthy is \$30 to \$35 per M. At Cordova, the lumber costs \$20 per M and at Seattle \$17. This gives a cost of from \$50 to \$55 per M for Alaskan lumber hauled 150 miles by rail, as contrasted with a cost of \$42 for Puget Sound lumber hauled 1000 miles by water plus 150 miles by rail. As a matter of fact, it is merely boycotting Alaskan products and throwing a little freight-tariff into the treasury of the Alaska Steamship Co., which is owned by the benevolent gentlemen that control the C. R. & N. W. R. R., the Kennecott Copper mine, and the A. S. & R. Co. The railroad and steamship rates from McCarthy depend upon the grade of the ore, 60% plus ore bearing a rate of \$32.50 per ton, between 50 and 60% a rate of \$30 per ton, and under 20% a rate of \$10 per ton. A flat smelter-rate, regardless of grade, of \$2.50 is charged at Tacoma on any tonnage. Officials of the C. R. & N. W. R. R. claim that their present revenue is not now sufficient to pay the interest on the bonded indebtedness of the company, and so it is not likely that these freight-rates will be reduced.

At McCarthy station a 300-hp. oil-burning boiler and an Allis-Chalmers turbine generator were installed. From McCarthy to the lower camp, which is 1½ miles below the mine, a 15-mile transmission line was erected of No. 4 hard-drawn copper wire, carrying current at 16,000 volts. At the lower camp this current is transformed to 440 volts, and is then delivered to the mine. A telephone line has been constructed, and is now in use from the lower camp to the mine. A two-story building for the use of officials, with offices for the president and general manager, dining and living quarters, has been erected at the lower camp. The company expects to make a bull-jig product of 50% copper. They expect also to ship a screened product composed of pulverized glance and copper carbonate, which will assay 20% copper. The mine will send down 200 tons of ore per day over the 6000-ft. Leschen aerial tram. The concentrate will be shipped to the smelters and the tailing stacked to run through a leaching-plant at a later time. It is estimated that 24,000 tons of 20% ore is broken and lying in the stopes. The Pringle vertical shaft is

to be sunk 600 ft. below the Pittsburg tunnel. For this purpose an electric hoist, manufactured by S. Flory & Co., of Bangor, Pennsylvania, has been placed underground. This is a second-motion herringbone-gear hoist having a capacity of 100 to 300 ft. per min. At the same time, the Rhodes tunnel is being driven 215 ft. below the Pittsburg tunnel to tap the Priegle shaft. This shaft will have two hoisting and one pump compartment and will be sunk in the orebody. The mine has been equipped with 25 piston and jack-hammer drills, and three electrically driven air-compressors of from 3 to 10-drill capacity. This company plans to build next year a 500-ton mill, installing a set of rolls, three Hancock jigs and Wilfley tables, together with a copper-leaching plant. It may be that a hydro-electric plant will be installed on McCarthy creek in 1919.

On the Kuskolina river the North Midas Copper Co., of which Ole Berg is manager, has developed a promising showing of gold and copper ore. The company has installed a Chicago Pneumatic Tool Co. compressor and will make regular shipments of gold ore 17 miles to Strelina, a station on the C. R. & N. W. R. R. The Chitina Kuskolina Mining Co., 12 miles from Strelina, installed a power-plant burning wood to drive its air-compressor. This company has an excellent copper prospect, but was disappointed during the past year by delayed shipments of machinery. It can do nothing of consequence until spring.

The Alaska Copper Corporation is operating the oldest property out from Strelina. This mine has been making periodic shipments for ten years. It has recently been taken over by Col. Stevenson of the Ladysmith Smelting Co., and will make regular shipments this winter. H. W. DuBois is manager. A considerable tonnage of moderate-grade copper ore has been developed by tunnels and a 300-ft. shaft. The property has been equipped with two Chicago Pneumatic Tool Co. air-compressors. The Alaska Westover Mining Co., of which C. C. Johnson is manager, has developed six feet of ore containing bornite and glance. This deposit occurs in the limestone and there are 3000 tons exposed by tunnels that could be mined during the winter. D. C. Bard made an examination of this property during the summer for the Ladysmith Smelter Co. interest.

## SPOKANE, WASHINGTON

NORTHWEST MAGNESITE.—UNITED COPPER.

The expenditures of the Northwest Magnesite Co. for the development of its quarries and the equipment of its plant at Chewelah will reach \$450,000, according to R. S. Talbot, president, who has just returned from a trip to California. The first appropriation, made more than a year ago, was \$250,000, but the operations and plans have since been expanded. Much of the additional equipment is being installed and will soon be ready for operation. Shipments are proceeding at the rate of six carloads daily; they are confined to the calcined material, which has about half the weight of the crude. H. K. Devereux, a mining engineer of Seattle, has been appointed manager for the company, with headquarters at Chewelah.—The United Copper Mining Co., operating at Chewelah, has purchased the Copper King mine, nearby, from H. S. Wales, who recently bought the property from the receiver for \$75,000. The price paid by United Copper is not given out. The purchase will give the United company a mile and a half on the strike of its vein.

The magnesite industry, employing 400 and 600 men at Valley and Chewelah, has been awarded a decreased payroll premium under the State Industrial Insurance Administration. Until this ruling was made the mining and transportation of magnesite in wagons has all been classed as quarrying, one of the heavy-risk industrial activities, and 5% of the payroll has been collected to care for accidents. The Commission has

segregated the employments in connection with magnesite mining, so that hauling the calcined product from the kilns to the railroad is put in a lower risk-class, and only 2½% of the payroll will be collected hereafter in this department. The remainder of operations are still regarded as in the quarrying class. The Commission has also put hauling of ore from metal mines, and lumber from mills, in the 2½% rate division. The new order complies with a request of the magnesite operators.—Mining men in the North-West are requested to send samples of ore to Spokane for exhibition at the annual North-West mining convention, February 11 to 17. Arrangements have been made for free transportation of these samples. The purpose in asking that ore be sent now is to give plenty of time for arrangement of the displays and also to avoid the likelihood of delayed freight trains which are more frequent later in the winter. Officers of the North-West Mining Association request that ore be sent from all promising prospects as well as from partly developed claims and mines. At previous conventions it has been noted that capital has frequently become interested in a prospect through the showing of ore.

## MAYER, ARIZONA

POCAHONTAS.—CIRCLE PEAK.—JEROME CONGER.—VERDE INSPIRATION.

Half a dozen or more important strikes of copper and silver-lead ore have been made recently in the Mayer district. High-grade chalcopryite has been found in the bottom of the 200-ft. shaft at the Arizona Copper mine, one and a half miles northwest of Mayer. The company has sufficient funds to sink the shaft 1000 ft. This discovery is especially interesting since it is close to the Butternut mine where some excellent ore has recently been found.—In the Copper Mountain district, the Monte de Cobre Mining Co., which recently took over the old Barbara mine, has gone through 40 ft. of ore in a new adit that has been run to tap a known body of copper ore. Indications point to this as one of the largest bodies of ore in the Copper Mountain district. The grade is not high but it is similar to the ore coming from adjoining properties in the schist.—South of the Barbara mine a strike of lead-silver ore has been made at the Pocahontas mine in a cross-cut at the 150-ft. level. The vein is about 12 ft. wide and averages \$15 to \$20 per ton. A carload of lumber has been purchased and a 50-ton flotation-mill will be erected as soon as the machinery can be assembled. This ore is similar to that of the Anderson-Birch mine, west of Humboldt, where flotation has been successful.—Two important strikes have been reported recently from near the old Hidden Treasure mine, south of Mayer. John Slak, of Mayer, has been developing a large group of claims called the Naco. The vein is about three feet with a rich centre, which will run from 60 to 70% copper. Two miles east of the Naco a group of claims is being developed by B. W. Gill. At one place a pit has been sunk 15 ft. on a strong vein carrying considerable glance and native copper. This vein outcrops for over 3000 ft. and is 20 ft. wide.—Between these two properties, J. D. Dillon and associates have opened the extension of the Naco vein with a 75-ft. open-cut which shows a large body of milling ore. These properties are near the railroad and are but a short distance from the Prescott-Phoenix highway.—A new camp will soon be established eight miles west of Mayer in the Pine Flat district by John A. Peacock, of Ft. Worth, Texas, who has organized the Circle Peak Mining Co. and taken over ten claims near the old Cumberlain mine and mill. About 2,000,000 ft. of pine timber covers the property. The ore carries copper, gold, and silver. The company also has an option on the Cumberlain property, which in the early days produced high-grade gold and silver ore. The wagon-road between these properties and Mayer is to be repaired.—Development work will be com-

menced in a few days on the Patton mine, which has been taken over by the recently organized Rio Tonto Copper Mines Co. P. J. McIntyre and W. D. Mahoney of Jerome are the principal owners. This is one of the best developed properties south of the Binghamton and Copper Queen mines.—The change in the officers and management that has been made at the annual meeting of the Big Reef Mining Co. will undoubtedly mean the early financing of the company and the resumption of the development work that, so far, has shown up some strong veins. It is understood that Eastern capital has been secured.—The Schist Belt Copper Co. has been organized by A. W. Davis, H. C. Storey, S. E. Wallace, Charles Hooker, and others. The property is north of the Silver Belt mine, west of Humboldt, and is on the strike of the Jesse and Union veins.—Indications are that there will be general activity in the Cherry Creek district during the coming year. Several new companies are being organized among the best mining men of the State.—J. H. Tribby, who is one of the oldest of the mine-owners in that district, has turned over four of his properties, the Evening Star, Climax, Three Metals, and the Shipper, to men residing at Pasadena, California, the deal having been consummated by W. A. Crawford of that city. The four properties are well developed, showing high-grade gold and copper ore.—In the same district, the Jerome Conger Mining Co. has acquired the old Conger mine. Henry Suder is president, Rudolph Baehr is vice-president, R. T. Belcher is secretary, and W. H. Hoover is treasurer. The company is to be financed by Ohio people. The ore carries gold and copper.—One of the best developed properties in the Cherry district is the Verde Inspiration, of which E. H. Meek is president and A. L. Hammond is secretary, both of Prescott. There are several parallel veins traversing the property; these have been extensively developed. At the Verde Inspiration mine several shafts have been sunk on different portions of the veins. The 20-ton stamp-mill has handled all the ore that has been mined up to now. The capacity of the mill is to be increased and concentration and cyanide equipment added. There is about 20,000 tons of oxidized gold ore blocked out and much ground has not been developed. The ore averages \$15 per ton in gold.

### DEADWOOD, SOUTH DAKOTA

HOMESTAKE.—ORO HONDO.—GILT EDGE-MAID.—TROJAN.

Richard Blackstone, superintendent for the Homestake Mining Co. since November 1914, has tendered his resignation to become effective January 1, 1918; he will be succeeded by B. C. Yates, who is promoted from the assistant superintendency. Mr. Blackstone has been with the Homestake for forty years, his first engagement being as civil engineer. He has had charge of nearly all of the construction done by the company, including the building of a railroad, later sold to the C. B. & Q., the development of water power for electric generation, the construction of the present water system, and numerous minor and incidental changes and improvements. Mr. Blackstone's energy and devotion to duty have been recognized by the board of directors in the substantial form of tendering him a handsome pension. Mr. Yates has been with the Homestake company for twenty years. Like Mr. Blackstone, his start was made in the engineering department. No assistant superintendent will be appointed at present.

John T. Milliken has purchased the Oro Hondo property, south of the Homestake, which he has been developing, under option, for the past three years. Deeds to the acreage were recently recorded in Lawrence county. This enterprise has been financed by Mr. Milliken in a search for the southerly extension of the Homestake orebodies. A shaft has been sunk to a depth of 2000 ft. On both the 1500 and 2000-ft. levels considerable exploratory work has been done, and on the latter extensive diamond-drilling. While Mr. Milliken has at all

times refrained from announcing any of the results of this development, the fact that he has purchased the property and that he has further announced the purchase of a large hoist from the Alaska Treadwell, to be moved to the Oro Hondo and erected, causes the belief locally that he has found ore and that another large mining territory will be opened on the southerly trend of the Homestake ore-zone.—The encouraging prices of lead and silver have stimulated ore extraction in the Galena district, a section which was idle for years. Several properties have been yielding good ore, which, although it occurs in small bodies, forms the basis for payable enterprises.—Construction of a spur to the Gilt Edge-Maid mine, which has been taken over recently by local parties, is a preliminary step to the resumption of operations. The mine is known to contain a large body of low-grade gold-bearing porphyry, which, it is believed, can be profitably treated on a large scale. The ore can be mined economically, either by 'glory-holing' or by steam-shovels, and is in such quantity that large equipment and extensive operation are justified. Taken in connection

PART OF SOUTH DAKOTA

with adjoining and neighboring properties, it promises to develop into a large enterprise. In the past the mine produced a considerable tonnage of smelting grades and later a cyanide mill treated upward of 50,000 tons of ore containing more than \$2 per ton.

Notwithstanding the high cost of materials and supplies and a decreased efficiency of labor, the Homestake during 1917 maintained a normal output and paid its usual monthly dividends regularly. Many of the skilled miners, attracted by higher wages paid in the copper camps and the Wyoming oil-fields, left the company, notwithstanding a wage increase of practically 50c. per day. The Homestake is paying practically \$4 per day to miners, besides furnishing rubber clothes for workers in wet places. The company's tungsten output was large and commanded a good market price. Five stamps are in continuous operation on tungsten ore, preliminary to its concentration. The ore contains some free gold, which is amalgamated, and the tailing is sent to the cyanide plants for further treatment. The gold content of the ores is sufficient to pay all costs of mining and milling, leaving the tungsten

concentrate as a clear gain from the operation. Completion of the second Spearfish hydro-electric plant is announced. This plant secures its water from Spearfish creek at a point above the first plant, and is returned to the stream for the benefit of that plant. This installation will give the company sufficient electric energy to drive all of its machinery in and about Lead, except the hoisting engines, which are steam-driven. This places the company in an enviable position regarding dependence on railroads and coal mines, and with the eventual electrification of hoisting plants coal will only be required for heating, and in emergency wood could be used for that purpose.

The adit being driven by the Mogul and Ofer companies to tap the North Lode, Mark Twain, and neighboring ore-shoots, is practically completed. From the portal of the adit to the Mogul mill, about half a mile, an aerial tram has been erected which will dispense with the necessity of railroad transportation of the ore from a large territory served by adit. For the past two years the Ofer company has been a steady shipper to the Mogul mill; it has a large tonnage of ore in sight.—Work is progressing rapidly on the construction of a loading-bin at Blacktail, where ore from the Republic, leased by the Trojan, will be delivered by team and motor truck, for transportation by the C. & N. W. railroad to the Trojan mill. A good supply of ore is being developed in the Republic; Trojan officials are well pleased with the showing so far made in this property.—Mill construction has been started at the Deadwood Zinc & Lead Co. property. Grading is completed and the stamps of the Lexington Hill mill are being removed to the new site. The company's operations are being financed by people of eastern South Dakota.

### MAMMOTH, UTAH

UTAH ZINC.—TINTIC-DELAWARE.—EUREKA LILY.—  
GRAND CENTRAL.

The Majestic Mining Co., incorporated to take over and operate 13 claims in the Erickson district, will start operations shortly. Considerable development has been done. Two years ago Charles Stauffenberg and associates equipped the mine with machinery and operated on the 100 and 170-ft. levels, mining some good copper, gold, and silver ore.—The Utah Zinc Mining Co. has started to haul the ore from its property in the Erickson district. This company during the past year has been developing ground on which there is a fine showing of lead-silver ore. One carload has been shipped and there is enough ore sacked to load three railroad cars. This ore has to be hauled by team 30 miles, costing \$7.50 per ton. The ore carries 40% lead and is sought by the smelters for fluxing on account of its high iron content.—The No. 1 shaft at the Iron Blossom is down 2000 ft. Frank Birch, the local manager of the Knight mines, says that it is the intention of the company to sink another 100 ft. and then send out drifts to cut the veins that have been developed on the upper levels.—The orebody in the Tintic-Delaware is increasing in size and richness. The two-foot lens of high-grade ore, running 80% lead, on the north side of the adit, has increased five feet, and the orebody, which showed a width of 20 ft. at the adit face, has opened to 25 ft. The road to the mine has been completed, but shipments to the smelter have been delayed because of cold weather. Attempts to make a shipment have been abandoned until sorting-sheds can be erected to protect the workmen.—The bad air condition in the Eureka Lily has been remedied temporarily by the use of a blower. The work in the mine has been handicapped for several weeks past by gases such as those found at the Tintic Standard immediately prior to the time the orebody was discovered. As a permanent relief from the gases, an incline is being run to connect with the old Lily shaft.—Recent development work in the Gold Chain resulted in the discovery

of an orebody which some years ago a prospect drift had missed by only a few inches.—Most of the ore is now coming from the levels above 500 ft.; it carries gold, silver, and copper.—Another dividend of 4c. per share, or \$24,000, has just been declared by the Grand Central Mining Co. at a meeting held recently at Provo. Checks were sent out on December 23 to shareholders of record on December 18. Reports from this mine indicate that one of the best orebodies that has been found in recent years is yielding a good portion of the present output. The ore was first discovered to the south of the shaft on the 2100-ft. level and since then it has been followed by means of a raise to the 2000-ft. level. The ore is low-grade, but the deposit is unusually large. A new piece of development work is to be started on the 2200-ft. level where a drift will be sent toward the north in an effort to find ore that has been developed on levels above.

### TONOPAH, NEVADA

TONOPAH EXTENSION.—TONOPAH BELMONT.—WEST END CON.—  
JIM BUTLER.

The Tonopah Mining Co. milled 11,350 tons of ore during November, averaging \$11 per ton, making a net profit of \$38,000. At the Silver Top, 52 ft. of development has been done, 14 ft. in the Mizpah, and 88 ft. in the Sandgrass. At the Mizpah shaft the stope on the Mizpah vein on the 600-ft. level continues on a 3-ft. face. On the 1100-ft. level of the Sandgrass raise No. 1163 made a connection with the level above and stoping has commenced.—At the No. 2 shaft of the Tonopah Extension Mining Co. 160 ft. of development has been done, and 168 ft. in the Victor. On the 1350-ft. level of the No. 2 the west drift from the 510 cross-cut shows a 4-ft. face of ore, while the drift to the east has a 3-ft. face of ore. Raise No. 567 advanced 22 ft. on a 4-ft. face of ore. At the Victor the 1501 winze continues in a face of ore. On the 1680-ft. level the 1600 south cross-cut advanced 64 ft. toward the extension of the Murray vein. West drift 1600 advanced 26 ft. on the Merger vein. The entire face of the drift is in ore. The production during the past week was 2380 tons.—On the 700-ft. level of the Tonopah Belmont Development Co. east drift No. 721 on the Shoestring vein struck a fault, and a cross-cut is being driven south to cut the faulted segment. On the 800-ft. level east drift No. 8017 and west drift No. 8018 each show a full face of ore. Raise No. 73 on the 1000-ft. level continues on a 1½-ft. stringer of good ore on the North vein. Last week's production was 2582 tons.—At the Ohio shaft of the West End Consolidated Mining Co. drift No. 535 struck a small fault, but recovered the vein. Winze No. 534 continues on excellent ore. On the 555-ft. level drift No. 1 shows a full face of good ore. Raise No. 814 from the 800-ft. level has reached 100 ft. above the level. Drift No. 2 at the West End continues on a face of low-grade quartz. The output during the past week was 859 tons.—At the MacNamara Mining Co. the west cross-cut No. 700 advanced 45 ft. without change. The production the past week was 504 tons.—The Jim Butler Tonopah Mining Co. at the Desert Queen shaft exposed 4 ft. of medium-grade ore in raise No. 653, which was started from the intermediate below the 500-ft. level. At the Wandering Boy raise No. 372 on the 200-ft. level made a connection, proving a large body of good ore. Raise No. 373 at present shows a 3½-ft. face of medium-grade ore. The production during the past week was 936 tons.

The Montana produced 338 tons, the Halifax 55 tons, the Midway 15 tons, and miscellaneous 41 tons, making the week's production at Tonopah 7655 tons with a gross value of \$133,962. As the Tonopah Mining Co., with an average of 2750 tons per week, gave no tonnage report for the week, the total production at Tonopah is not given in full.—The silver vein, recently uncovered by the Tonopah Divide Mining Co. at Gold Mountain, shows considerable molybdenum minerals.

## CALIFORNIA

### ALAMEDA COUNTY

On December 12 Judge Henshaw, with Justice Shaw, Sloss, Melvin, and Angellotti of the Supreme Court of California concurring, upheld the decision of the lower court appointing a receiver to take charge of and operate the mines of the Western Magnesite Co. The receiver was originally appointed because of dissension among the directors of the company, preventing the operation of the magnesite mines. Now that the Supreme Court has confirmed the appointment of L. E. Boyle as receiver, operations at the mines will be resumed. The property of the Western Magnesite Co. is situated at Livermore and is said to contain an extensive deposit of excellent-grade magnesite.

### CALAVERAS COUNTY

(Special Correspondence.)—The Stockton Ridge Consolidated Mining Co., which controls the Hexter gravel claims, has definitely shut-down. There is a 3800-ft. adit on the property, and it will take some time to remove the rails and dismantle the pumps. Everything is for sale, including the mill. When work ceased there was a large body of gravel in sight; the high cost of powder and labor was the cause of shutting-down. H. S. Chapman, the superintendent, connected at one time with the Greenwater boom, is leaving for Chile, South America, shortly. The company has spent in the neighborhood of \$400,000.—The Buffalo gravel mine, situated in Chili gulch, has shut-down after a mill-test of several tons of gravel. The company erected a plant, including transformers, electric hoists, and Deister tables, before ascertaining what was in the ground.—A slight accident to two men in the Crazy Bird mine took place recently, otherwise the mine is running smoothly. The orebodies are proving themselves with depth. This is the only mine in the district offering work to miners.—The Fischer quartz mine has erected a head-frame, and is unwatering and re-timbering the shaft. San Francisco capital, headed by Benjamin F. Lyle, is interested.—A 30-ton mill-run has been made at the Buffalo mill from the Chili gulch claims owned by George Edwards and Frank Bernardi. The return gave a \$12 recovery on the plate and one and a half tons of concentrate that assayed \$1700 per ton.—The Maypole quartz mine, which is temporarily shut-down, has a 6-ft. vein at the face of the adit, which is in 365 ft. Samples have been taken, going as high as \$68.72 per ton. The future of the district is in the quartz, and there are a lot of good prospects and partly developed mines awaiting the magic touch of capital to become steady producers.

Mokelumne Hill, December 17.

### DEL NORTE COUNTY

(Special Correspondence.)—At the different mines within 30 miles of Crescent City, the water-shipping point, 5000 tons of high-grade chrome ore has been developed and 1000 tons mined and on the dump ready for delivery. The mines are situated  $4\frac{1}{2}$  to  $13\frac{1}{2}$  miles from the present wagon-road, but a good road is being constructed to connect them with Crescent City. These mines are owned and operated by George S. Barton of Grants Pass, Oregon.

Crescent City, December 18.

### ELDORADO COUNTY

(Special Correspondence.)—Six miles south of Placerville, where Squaw Hollow creek empties into Martinez creek, just south of the Martinez gold mine, the Pacific Gold Mining Co., of South Dakota, is running a cross-cut west from Martinez creek 1000 ft. to cut the main Mother Lode of California at a vertical depth of 520 ft. The cross-cut is being driven at the rate of 200 ft. per month, by night and day shifts working with air-drills. It is now in more than 600 ft. and will be completed about the middle of February 1918. A 30-ft. vein of free-milling gold quartz, averaging \$1.26 gold per ton, has already been cut. The work is in charge of Anthony Crafton.

Placerville, December 11.

### SHASTA COUNTY

(Special Correspondence.)—The new 5-stamp mill of the Shasta Hills Mining Co. on the Sybil and Accident mines west of French gulch was started this week. E. Hillman is superintendent.—The Crescent Copper Co. has filed its articles of incorporation. The company has mines near Keswick. John E. Baker is general manager.

Redding, December 10.

(Special Correspondence.)—The Victor Power & Mining Co. at Harrison gulch has unwatered the Midas mine to the 600-ft. level.—The Shasta Hills Mining Co. has started up a new 5-stamp mill on the Accident & Sybil mine, four miles west of French Gulch.—Shipments of ore from the Bully Hill mine to the smelter at Kennett have been increased to three carloads per day.—The Yankee John mine, four miles west of Redding, is sinking its shaft 100 ft. deeper.—The Mammoth Copper Co. at Kennett, being unable to get prompt delivery of mining timbers by railroad from the mills up the canyon and in Oregon, is now having material hauled by auto-trucks from Shingle Shanty, eight miles from French Gulch. The haul is 41 miles.

Redding, December 16.

### SIERRA COUNTY

(Special Correspondence.)—The Sierra-Alaska Mining Co., operating at Pike City, has arranged for a survey for a lower adit site on Oregon creek. The adit will be driven to cut the vein at a depth of over 500 ft. below the bottom of the shaft, and will be a mile long. Following its completion the shaft will be also deepened. The adit is designed to drain the property besides becoming the main working level. The vein in the shaft is stated to be yielding excellent ore.—Reese Bros. are developing the Mexican group, near Downieville, under a bond and purchase option. The 10 stamps formerly operated at the Hayes Consolidated have been moved to the Mexican mill, which at present contains five stamps; 15 men are employed and some underground work is proceeding, although the manager is centring work on surface improvements. The Mexican is owned by the Yorke Bros. of Downieville.—H. N. Yates of Pacific Grove and D. C. Smith of Meridian have completed an examination of the Irehan mine, near Alleghany, in which they are heavily interested. The new mill is running steadily on ore of good grade; recent developments have been encouraging.—The Hilda Mining Co. has completed a road from near Milton to its property, and is freighting lumber and supplies with two motor trucks. An excellent camp is

being rushed to completion and, if the buildings can be finished before deep snow sets in, the property will be worked all the winter.—Rich gravel continues to be mined from the new deposit in the Hilo mine, above Downieville.—The Loftus Blue Lead Gravel Co. has everything in readiness for hydraulic mining along Slate creek. The company is also developing large areas of virgin territory in the vicinity of St. Louis, Howland Flat, and other old camps. The water supply for the giants has been greatly improved.

Downieville, December 16.

#### SISKIYOU COUNTY

(Special Correspondence.)—As a result of the closing of Klamath river the past weeks, prospectors had an opportunity to find the gold in the river bed and high-bed points. While no sensational strikes were reported, it is believed the miners were given a chance to find the gold deposits for wing-daming next year.—The placer-mine operators throughout the county are making special plans to save the platinum in gold-bearing gravel during the coming season.—H. J. Barton has leased his Beaver Creek placer mine to Owens, Baldwin & McAllister of Oak Bar, who are operating with a large crew.—The Mercury company recently purchased the Cowgill quicksilver mine, at Cinnabar Springs, and has completed a retorting plant operated by electricity.—Florin and Charles Le May are shipping ore, running 50% chromic oxide, from their Lime gulch mine.—Henry Muskgrave of Oak Bar is opening a large deposit of chrome in the Greenhorn district.—J. W. Dyer and Van Fleet of Yreka are developing the Dyer chrome property below Hamburg on the Klamath river.—Fred Myers and Barney Nelson of Sawyers Bar in a recent clean-up on their Jackson Creek placer mine recovered a \$200 gold nugget.—The Grey Eagle Copper Mining Co., at Happy Camp, is operating with 50 men.—William Might, of Happy Camp, while at Yreka recently, exhibited \$1000 worth of gold nuggets, which he cleaned up during the last three months in his Humburg Creek placer mine.—John Boyle, of Yreka, who is operating the R. S. Taylor quartz mine in that district, reports a rich strike of \$1000 gold ore.

Hornbrook, December 7.

#### COLORADO

##### CLEER CREEK COUNTY

A snow-slide down the sheer side of Red mountain, near the Urad mines, carried away 20,000 ft. of timbers that had been framed for the new concentrator at the Molybdenum mines. The mill-site is safe from snow-slides, but the lumber had been unloaded near the site in a spot where slides often occur.

##### SAN MIGUEL COUNTY

Tonopah Belmont people have taken over the Alta mines in this county and have placed J. M. Fox in control as manager.

##### TELLER COUNTY

Production from the properties of the Granite Gold Mining Co., the Dillon, Granite, Dead Pine, Monument, and Gold Coin mines on Battle mountain, for November, amounted to 145 broad-gauge cars, or 4300 tons, which was the heaviest in the life of the company.—The ore averaged \$21 per ton; it was shipped to the Golden Cycle M. & R. Co.'s plant at Colorado Springs. The company paid its regular bi-monthly dividend of 1c. amounting to \$16,500, on December 10. The sum of \$49,000 has been paid in dividends this year. The report of A. E. Carlton, president of the Cresson Consolidated Gold Mining & Milling Co., accompanying the December dividend checks, announced a new discovery of ore, carrying a gold content of 32.5 oz. or \$650 per ton, in the raise between the 1600 and 1500-ft. levels. The ore shipped in November yielded a net return of \$129,971 above operating cost and the company has cash in bank of \$1,260,000, and 16 cars of ore in transit, of an estimated value of \$16,000.—The November produc-

tion from properties of the Elkton Consolidated Mining & Milling Co., on Raven hill, operated by lessees totaled 425 tons from the main shaft, with a bullion value of \$8500. In addition, lessees on Tornado mine of the company shipped two cars of about \$30 grade.—A five-year lease has been issued to the Patterson-Bradley Leasing Co., H. G. Gones, general manager, on the Specimen and Sacramento mines, Bull Hill, by Stratton's Cripple Creek Mining & Development Co. The new company is adding an electric hoist and compressor.—The Clyde shaft, of the Millasier Mining Co., on Battle mountain, has reached a depth of 1300 ft. Charles Fish, the superintendent, is now cutting stations at the 1100 and 1300-ft. levels and will then continue sinking to the 1500-ft. point.—A new surface discovery has been made on the New Boston, a Stratton Estate property on Womack hill, by Dworsk and Green, lessees. The first shipment was sent out last week and is estimated at \$20 grade.—The annual stockholders meeting of the Free Coinage Gold Mining Co. was held at South Altman, on Bull hill, on December 15, when the following directors and officers were re-elected: J. B. Neville, Denver, president and general manager; Charles Cavendar, Leadville, vice-president and treasurer; and A. S. Neville, Denver, secretary.

#### IDAHO

##### LATAH COUNTY

(Special Correspondence.)—A promising strike of copper ore has been made recently at the Mispah mine, the property of the Merger Mining Co., of Palouse. The mine has been worked for a number of years and some 2000 ft. of development work has been accomplished; during the last two years, however, work has been confined to that required to secure the patent. Last spring Ernest Northrop, one of the principal owners, found some good float between the two adits the company had driven, and a little prospecting uncovered a body of carbonate ore. An adit was started, and has been driven for 50 ft. on a vein ranging from 5 to 15 ft. A second adit was started to cut the vein at a lower level, and this has cut a body of massive chalcopyrite and pyrrhotite in a gangue of micaceous schist. A trial car of the oxidized ore gave a return of 17% copper.

Moscow, December 22.

#### MONTANA

##### SILVER BOW COUNTY

The copper production of the Butte district is at normal or better for the first time since the beginning of the I. W. W. labor troubles in June last, according to a statement issued by the local office of the Anaconda Copper Mining Co., which showed a production of ore of 15,042 tons December 14, while the normal is estimated at 14,300 tons daily, without the ores of the North Butte company, which approximate 1700 tons per day. The production of zinc ore is below normal, but this is chiefly because the Anaconda has a five months stock of zinc concentrate at its electrolytic plant at Great Falls, awaiting reduction, in addition to a large stock of crude ore at the Washoe zinc concentrate, which it is calculated will keep the plant busy for some time. The spelter market is at a low ebb and under the prevailing mart the Anaconda has found it unprofitable to pay custom shippers 1½c. per pound for zinc and has reduced its settlement schedule to ¾c. per pound. The Anaconda also has found it necessary to shut off receiving further zinc ores from the Coeur d'Alene and has effected a drastic curtailment in its own output of zinc ores from the Butte district.

#### NEVADA

##### MINERAL COUNTY

(Special Correspondence.)—Several of the largest mines at Candelaria, including the Chief of the Hills, Northern Belle, Mt. Diablo, and Holmes, have been taken under option by

Charles E. Knox, of the Montana-Tonopah Co., who is reported to be acting for Eastern capital. Large quantities of ore are in the old workings, and some rich shipments have been made recently by lessees. The prospective buyers intend to erect a modern milling plant.—On the 250-ft. level of the Nevada Rand, in the Rand district, No. 2 vein has been cut and shows a wide face of \$130 ore; 16 tons is ready for shipment to the Hazen sampler. Ore shipped from the 180-ft. level of this vein carried \$77 in gold and silver. Preparations are being made to open the vein on the 350-ft. level, and later to seek it on the 450. No. 1 vein has been cut on the 150, 180, and 250-ft. levels, and 35,000 tons, averaging \$15 per ton, is blocked out. Charles Huber, of Tonopah, is president; W. V. Ruderow, Reno, secretary and representative of Eastern interests; S. E. Montgomery, Reno, consulting engineer.—Tests on ore from the Walker River copper group, near Mina, have proved satisfactory in the 20-ton experimental leaching-plant, and it is planned to erect a 100-ton unit in the spring. R. F. Banks is metallurgist, and Joseph Gelder manager. A new compressor has been added to the equipment, and development at the mine is proceeding steadily.—The Empire Nevada, under management of Joseph Gelder, is shipping 40 to 50 tons of first-grade ore daily. The bulk of this is from the Ross, Hart & Hair lease.

Mina, December 15.

#### STOREY COUNTY

(Special Correspondence.)—Two shipments of bullion, aggregating \$40,000 to \$45,000, have been made from the Mexican mill, representing a week's run on ore from the Union Consolidated. Splendid ore continues to develop on the 2300 and 2400-ft. levels, particularly in the southerly workings from the latter. New stopes are being opened and preparations made for prospecting new ground.—From the 2300-ft. level of the Mexican an easterly cross-cut has been started, to prospect territory adjacent to the rich area in the Union Consolidated.—The Sierra Nevada is repairing old workings on the 2500-ft. level and expects soon to reach a point where good ore was exposed 35 years ago.—Driving to the west from the 2700-ft. level of the Consolidated Virginia is progressing.

Silver City is showing activity, and several old properties are worked by lessees. In the Silver Hill, Robohm & Windisch is working several blocks of ground and keeping the Donovan mill supplied with ore running high in silver and gold.—Alex. Armstrong and L. S. Cain are opening a good ore-shoot in the Hayward, and Charles Silva and Harry Cardeu have taken a lease on the Lager Beer.—The Golden is being worked by Simon Conwell and associates, and Hickey & Hardwick are extracting good ore from the Oest group. The Mt. Bullion, Occidental, and other properties are active. With silver at present price much ore in old workings is being profitably extracted.

Virginia City, December 17.

### OREGON

#### JOSEPHINE COUNTY

(Special Correspondence.)—Concentrating machinery is being erected at the Golconda chrome mine. The mine has been producing steadily during the summer.—The Oak Flat mine, leased by the California Chrome Co., has developed 2000 tons of ore, which will be ready for shipping next spring.—G. S. Barton has 400 tons of chrome ore ready for shipment at his mine 14 miles from Grants Pass.—In this county there are a number of deposits, isolated by lack of roads, which would be opened if chrome prices attained a higher level.

Grants Pass, December 17.

### SOUTH DAKOTA

#### FALL RIVER COUNTY

Drilling for oil has commenced in the Ardmore field and

the Hat Creek company has its well down over 500 ft. The Shiloh company and the Des Moines company are drilling also. It is expected that the oil-sands will be reached at a depth of about 2000 ft. and the presence of oil will be determined soon after the first of the year. At the Shiloh well the gas zone has been passed. Other lands have been leased in the same district and additional rigs will be placed in commission next year.

Lead, December 7.

#### LAWRENCE COUNTY

In the issue of December 22 it was stated in error that the Homestake had declared a special dividend of \$1 per share, so that the total dividends paid by the company in 1917 amounted to \$7.80 not \$8.80, as stated, and the total distribution to stockholders to \$1,959,048, not \$2,210,208.

### TEXAS

#### BROWN COUNTY

(Special Correspondence.)—A nine-foot orebody assaying 48% lead, 6% silver, and  $4\frac{1}{2}\%$  copper has been discovered upon the farms of Lee Baker, six miles west of Bangs. The ore is found at a depth of 90 ft. The property has been leased by Mr. Baker to the Knox County Copper Co., and a shaft is being sunk.

Bangs, December 17.

#### EL PASO COUNTY

(Special Correspondence.)—Charles Davis of El Paso has purchased at a receiver's sale the tin mine, situated in the Mt. Franklin range, 14 miles from El Paso, the consideration being \$21,000. Mr. Davis was one of the original stockholders of the company that owned the property. He plans to resume development. This mine was opened in 1883 and more than \$250,000 has been expended in the development of the orebody and the erection of a mill. The property comprises about 3500 acres. Shipments of tin were made from time to time, but on account of a disagreement among the stockholders the company was thrown into the hands of a receiver. An abundant supply of water for all purposes is available, there being three springs upon the property.

El Paso, December 15.

### CANADA

#### BRITISH COLUMBIA

F. A. Starkey, a mining broker, announced on December 11 that one of the largest mining deals in British Columbia has practically been completed, the Utica Mining Co. negotiating with C. F. Caldwell for the purchase of the Sunset and Bell mines for \$70,000 cash and \$800,000 in stock in the new company.

Flotation will be used by the Canada Copper Co. in concentrating the ore of the Copper Mountain mine, for which it is building a concentrator of 3000 tons daily capacity. The concentrate will be nodulized in rotary kilns. Experiments have shown that the fine flotation concentrates can be made suitable for smelting in this way.

The Granby Consolidated Mining & Smelting Power Co. has ordered two large converters for its smelting plant at Anyox, which are expected to increase the capacity by 20%. The production of the Anyox smelter will be 30,000,000 lb. of copper this year. The additional equipment should increase this by 6,000,000 lb. and raise the total to 36,000,000 on the basis of the 1917 production. The production of 1917, however, is not quite representative, being 5,000,000 lb. less than in 1916. The rest of the plant has sufficient capacity to meet the demands of the new converters. It is believed that capacities in other departments are to be increased, as the cost of the converters would not equal the appropriations the Granby company is reported to have made for this smelter in 1917. The dimensions of the new converters are 20 by 20 ft., as compared with 12 by 12 ft., the size of three converters in use. The capacity of a new converter will be more than three times that of the three of

less size. The erection of the first converter will be completed by February 1, it is believed, and the second soon after. One will be used continuously and the other will be held in reserve for emergencies. Anyox is receiving about 75,000 tons per month, of which 10,000 is from its lesser mines and its patrons and the remainder from Hidden Creek. Preparations are proceeding for the erection of a coking plant on Graves Point, Anyox. The ground has been graded for 30 by-product ovens. The coal will be removed by barges from the Vancouver island mine of the Granby company. It is estimated that the cost of the deposit and its development and of the coking plant and transportation equipment will be \$2,500,000.

Mining men are noticing with much concern that there seems no likelihood of the Trail smelter being re-opened. The plant was closed a few weeks ago owing to a strike of the 1600 employees who demanded an all around eight-hour day. Only about 350 men would have been affected by the change. Apparently all negotiations for settlement have broken off. The fires in the furnaces have been drawn.

Production of zinc in British Columbia is steadily becoming more important. The value of zinc produced in 1909 was only \$400,000. For 1910 it was \$192,473, and for 1911, \$129,092. Thereafter there was gradual improvement up to \$346,125 for 1914. Then came a comparatively big increase, to \$1,460,524 for 1915, and a still bigger advance in 1916, to \$4,043,984. The total for zinc to the end of 1916 was \$7,212,759.

The Consolidated Mining & Smelting Co. of Canada has declared its usual quarterly dividend of 2½%. Payment will be made January 2 to stockholders of record on December 15. The aggregate of the disbursement will be \$210,695. This will increase the total payments to \$3,794,121. Payments this year aggregate \$842,780. The declaration of this dividend at a time when the smelter at Trail, B. C., and some of the company's mines are idle created little surprise in mining circles in view of the stability and long standing of the corporation. There is enough lead on hand at Trail to supply the average demand for three months.

#### YUKON

The dredge of the Yukon Gold Co., which is a Guggenheim organization, has given employment to a large force of men for many months under the supervision of A. D. Hughes; it began elevating gravel on December 6. The try-out proved the big machine to be in perfect working order and it is now in steady operation, working two shifts of nine hours. The dredge was assembled a mile below Murray and was launched a month ago; it was used by the company in Alaska. It is of almost solid steel construction and has more the appearance of a battleship than a machine to separate gold from alluvial gravel. The dredge is headed down stream and after working a certain distance in that direction will be turned and worked up stream. The Yukon Gold Co. arranged with the Washington Water Power Co. to extend its transmission line to furnish electric power to drive the big machine. This necessitated the construction of 12 miles of new line, much of it over high mountains, across deep canyons, and through heavy timber. This line will prove of great benefit, as it makes electric power available for other mining operations along the route. The Yukon Gold Co. has acquired all the placer ground along Prichard creek, extending from the mouth of the creek to the source, a distance of 14 miles. Last year the ground was systematically prospected with Keystone drills for a considerable distance below and above Murray, and as a result the engineers of the company estimated the gold to be recovered from the ground prospected at approximately \$2,000,000.

A rich strike in copper ore has been made on Williams creek, near Yukon Crossing, by Dawson men. A tunnel has been run into the hill 180 ft. and splendid ore has been found all the way. The strike is on one of the group of ten copper claims on Williams and Merritt creeks.

## PERSONAL

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

MORTON WEBBER is at Butte.

B. F. BECKWITH, of Anaconda, is here.

J. C. HOPPER is at Silverton, Colorado.

C. F. SHERWOOD, of Salt Lake City, is here.

GEORGE A. FARISH has returned from Salvador.

RENSSELAER H. TOLL is at Berkeley for the holidays.

H. L. MEAD has returned to New York from Alaska.

J. P. NORRIS, of Rome, New York, is at Hamilton, Ontario.

J. K. TURNER was here from Goldfield, Nevada, this week.

ROBERT H. BEDFORD has gone to Cuba on a mine examination.

WALTER KARRT-DAVIES has returned to Berkeley from New York.

D. C. JACKLINE has returned to San Francisco from Washington.

NELSON DICKERMAN has returned to San Francisco from Salt Lake City.

J. ROEBLING JARVIS, of Idaho City, Idaho, has gone to Belmar, New Jersey.

J. C. KENNEDY, of Manhattan, Nevada, spent Christmas in San Francisco.

D. D. MUIR is manager for mines for the U. S. Smelting Co. at Miami, Oklahoma.

WILLIAM G. REYNOLDS is Captain of infantry (U. S. R.) at Fort Sheridan, Illinois.

W. H. SEAMON JR. has joined the 27th Engineers and is at Camp Meade, Maryland.

E. M. ROGERS passed through San Francisco on his way from New York to Los Angeles.

E. J. JENNINGS, formerly foreman of the Chino leaching-plant, has joined the Navy.

HUGH F. MARRIOTT is president elect of the Institution of Mining and Metallurgy, London.

RUSH M. HESS is at St. Louis, on his way to Birmingham, Alabama, from Bouse, Arizona.

ROSCOE H. CHANNING has obtained a commission as Captain in the Field Artillery, U. S. Army.

RICHARD BLACKSTONE has tendered his resignation to the Homestake Mining Co., to become effective on January 1.

FREDERICK LYON, vice-president of the U. S. Smelting, Refining & Mining Co., has been in California on a tour of inspection.

VICTOR C. ALDERSON, president of the Colorado School of Mines, was here before Christmas on his return from Los Angeles to Golden.

BRACE C. YATES, assistant superintendent for the Homestake Mining Co., has been appointed superintendent in succession to Mr. Blackstone.

L. DOUGLAS ANDERSON, superintendent of the Midvale smelter, has been appointed smelter manager for the United States Smelting Co. at Salt Lake City.

L. F. S. HOLLAND, until recently field engineer for the Consolidated Arizona Smelting Co., has been appointed consulting engineer to the Arizona Mines & Reduction Co., with headquarters at Wickenburg, Arizona.

An unsigned letter from Washington, dated December 5, on 'Flotation Physics' has been received. The Editor desires to know the name of the writer.

## Book Reviews

THE COMPOSITION OF TECHNICAL PAPERS. By Homer Andrew Watt, assistant professor of English in New York University. 16mo. Pp. 431. McGraw-Hill Book Co., Inc., New York. Price, \$1.50 net.

This is an elementary book for students and engineers without university training. A little more than a third of the volume is devoted to examples of technical writing. Among the exemplars we recognize John Carty, Charles Going, and the greatest of all scientific expositors, Thomas Henry Huxley. Messrs. Carty and Going are to be felicitated on being in such company. Mr. Watt, like most writers on the subject, illustrates unintentionally the errors against which he preaches. For example, in the preface he says: "The division between the liberal and the professional aims is not, in the case of instruction in English composition, sharp, since any engineering student who receives one type of instruction will receive with it much of the value contained in the other type." This is true, but it is badly expressed. We suggest: "The division between the liberal and the professional aims of instruction in English composition is not sharp, since any engineering student that is helped by one kind of instruction will receive benefit from the other kind." It is well to place modifying words or phrases close to the words that they modify; it is also well to avoid the use of such words as 'case', 'instance', 'nature', and 'character'. See Quiller-Couch 'On Jargon' in 'The Art of Writing'. Immediately after the sentence quoted above we find the statement: "Every engineering student should certainly have a general course in English composition." Surely; and when he has done so he will place his adverb where it is most significant; he will write: "Certainly every engineering student should have a general course in English composition." A few lines lower we find: "But the bulk of whatever writing they will do *will* almost certainly *be* of a professional kind, and a specific course in the composition of technical papers *will*, therefore, also *be* of undoubted service." The disjointed portions of verbs are indicated by italic. Avoid the splitting of verbs. We suggest that the conjunction 'but' is continuative and therefore should not begin a sentence. 'Certainly' is an adverb that does not lend itself to qualification. 'Specific' has taken the place of 'special'. We venture to submit an alternative phrasing: "The larger part of their writing is likely to be done in the exercise of their profession, therefore a special course in the composition of technical papers is sure to be of service." So much for the preface. Chapter I begins with a quotation from "a well-known New York engineer," who is reported to have said: "An engineer who is inarticulate is quite as useless as one who is professionally incompetent." The assertion is nonsense. A competent engineer does not become incompetent because he is inarticulate; it is only his ability to transmit information that suffers. An incompetent engineer becomes pestiferous when he is articulate. Such statements are detrimental to interest in a subject having an importance that needs no exaggeration. As Mr. Watt himself says: "The man who has not the power to give his ideas clearly to others, the man whose thoughts are locked in his brain simply because he has not the ability to communicate them, suffers under a handicap which no amount of professional knowledge can possibly overcome." We believe that to be true and for that reason we rejoice to see the publication of books intended to arouse the engineering profession to an intelligent interest in technical writing. This book may serve that purpose.

T. A. R.

THE LIFE OF ROBERT HARE, AN AMERICAN CHEMIST. By Edgar Fahs Smith. Pp. 508. Ill. Index. Oct. de luxe. J. B. Lippincott Co., Philadelphia, 1917.

If one were to name the fathers of American chemistry, he

would necessarily mention Hare and Silliman. In some way Silliman caught the public eye more than Robert Hare. It would be foolish to attempt to give precedence to either. They were bound to each other by ties of friendship such as seldom exist between men, so that in large measure the work of one was the work of the other, a building up through intercommunication of two of the most progressive scientific intellects of the age. Hare was a Philadelphian, and it is interesting to note that the man of native genius and the stimulus with which to develop him appeared together. Philadelphia was distinctly the centre of scientific culture and progress in the early days of the Republic. It was in Philadelphia that the oldest chemical society in the world, namely, the Chemical Society of Philadelphia, was founded in 1792. It was to Philadelphia that Franklin went to make his home, and where many of his notable scientific achievements were accomplished. Again, it was to Philadelphia that Joseph Priestly, fleeing from persecution in England, came to continue the work of his choice. Here Robert Hare was born in 1781. He was connected with a chemical industry, which, however, was not as acutely chemical in those days as it is in our own, his father being the owner of a brewery. It must be noted, however, that his father, an Englishman by birth, who came to America in 1773, was prominent in the public life of the day, and was no common artisan, as were many brewers of that period. He was a member of the Constitutional Convention of Pennsylvania, serving the State as senator, and he was also one of the trustees of the University of Pennsylvania. It was with this institution that his son's great life-work is associated in the public mind.

The achievements of Robert Hare are traced in this book with the appreciation of a biographer who is a master in the science that Hare did so much to establish, and he is, furthermore, a worthy successor in the chair which Hare occupied in the same university. The most sensational discovery which Hare made was that of the oxy-hydrogen blow-pipe, by which he was enabled to fuse platinum, which was then invested with a certain sanctity because of the inability of man to fuse it in the past. But the invention of the oxy-hydrogen blow-pipe was of vastly more consequence in its demonstration of the real nature of combustion, a phenomenon that previously had not been understood. The account of the activities of Robert Hare from the period of this remarkable discovery in 1801 to his death in 1858 involves passing in review the higher development of physics and the great revelations of the chemical properties and relations of matter from the epoch of the misunderstandings of the alchemists, whose views of matter was just being supplanted at the time when Hare began his work. There is consequently no better way to trace the development of science through the first half of the nineteenth century than by a perusal of this work. Hare was equally distinguished in his directive influence upon the development of electrical knowledge. He devised the first electric furnace, which, however, he called a deflagrator, in which he converted charcoal into graphite, thus anticipating Acheson by about 70 years. Also, with this apparatus, he produced calcium carbide, elemental phosphorus, and calcium. It may be said that if Hare had known how to bring his remarkable discoveries to the attention of the world, or had cared to do so in the way that is now common among scientists, the advancement of practical science would have been much more rapid. Some of his most notable experiments were demonstrated before small groups of appreciative scientific associates, and then forgotten, so that their importance, from the standpoint of general advancement in industry, was overlooked. Ira Remsen, in 1915, called attention to the remarkable fact that work which he was pursuing and considered new at that period, he was astonished to find had been investigated by Robert Hare as early as 1821, and that similar conclusions had been reached at that time by this extraordinary pioneer in

chemistry. The book is so full of valuable information that it will prove a great addition to any chemist's library.

**NOTES ON MILITARY EXPLOSIVES.** By Erasmus M. Weaver. 8vo. Pp. 382. Index. Fourth edition, revised and enlarged. John Wiley & Sons, Inc., New York, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$3.25.

This authoritative treatise on a subject of pronounced importance and of great interest at this moment is enriched by an important discussion on 'The Role of Chemistry in the War', by Allerton S. Cushman, director of Industrial Research, Washington, D. C., in which is given an illuminating discussion of the basic chemical action of nitrogen, carbon, hydrogen, and oxygen in all explosives. It may be said, for the benefit of those who have not seen the book before, that General Weaver, who is chief of Coast Artillery in the U. S. Army, has given an introductory chapter on the principle of chemistry, which is so simple that any man of general education would be prepared for an undertaking of what follows, even though he had not devoted a large amount of attention to chemical subjects. He then discusses the various types of explosives, service-tests of explosives, and proper methods of storage and handling. As a convenient handbook, it is a most commendable treatise.

**EXAMPLES IN BATTERY-ENGINEERING.** By F. E. Austin. Pp. 90. Index. Published by the author. Hanover, N. H., 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.25.

This is another one of the practical little books on electricity for which Professor Austin has already acquired a wide reputation. He has the faculty of giving a clear statement to problems, so that they may be readily comprehended by students who are working their own way. Professor Austin points out that battery-engineering offers an opportunity to develop and to store energy where at present it is allowed to go to waste. For example, he calls attention to the need of gasoline, which is employed chiefly as a generator of power for automobiles. His suggestion is that storage batteries should be employed more generally, and that it would be possible to utilize the wasted energy of the winds by windmills for storing up electric power, which could be drawn upon as needed. He says "Two windmills each 25 ft. diam. properly arranged, would, in many parts of the world, furnish sufficient power for the needs of a fair-sized farm, and the necessary power for transporting farm products to market. \* \* \* Another source of power may be the sun's rays acting upon a thermo-pile that may charge storage cells while the sun is shining. These could then supply low-pressure high-efficiency incandescent lamps during the hours of darkness." It is a suggestive and interesting little book.

**MACHINE DRAWING.** By Ralph W. Hills. Pp. 92. Ill. Index. McGraw-Hill Book Co., Inc., New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.

This valuable little book was prepared for use in the Extension Division of the University of Wisconsin, and is the sort of thing that a student obliged to work his way alone will welcome. It covers the essentials of machine-design in its more simple aspects, and gives practical instruction in draughting and in the production of acceptable high-grade drawings and tracings.

**REVIEW OF THE GEOLOGY OF TEXAS.** By J. A. Udden, C. L. Baker, and Emil Böse. Pp. 164. Inserts and maps. Bulletin of the University of Texas No. 44.

The awakening interest in the mineral resources of Texas makes the re-appearance of this bulletin timely. It gives the geological history, with a special chapter on the economic minerals, aided by small maps as well as by a large colored map of the State, on which are valuable geologic columns.

## Recent Decisions

### MINER'S LIEN—"LABOR" DEFINED

'Labor' within a miner's lien statute means physical labor unequivocally performed on the property. Failure of a mining lien in foreclosure proceedings does not necessarily involve the validity of the defendant's indebtedness to claimants.

*Stuart v. Camp Carson Mining & Power Co. (Oregon)*, 165 Pacific, 359. June 6, 1917.

### COTENANT OF MINERAL GROUND—INJUNCTION DENIED

The taking of minerals from land will not be enjoined at the suit of a party claiming only an undivided one-sixth interest in the land where the injunction might work great injustice upon defendant in its mining operations and there does not appear in the bill grounds for such a drastic proceeding. The remedy by injunction in favor of a co-tenant is to be sparingly exercised.

*Wilmer v. Philadelphia & Reading Coal & Iron Co. (Maryland)*, 101 Atlantic, 538. June 26, 1917.

### OIL AND GAS LEASE—FORFEITURE—CONSTRUCTION

An oil and gas lease which binds the lessor but is optional with respect to the lessee will be construed most strongly in favor of the party bound and against the party not bound. After a lessor has declared an oil lease forfeit and leased to another, the first lessee cannot come in and set up the failure of the second lessee to carry out his contract, in an attempt to re-establish his own right to possession. The lessor alone may avail himself of forfeiture clauses.

*Beerman v. Dux Oil & Gas Co. (Oklahoma)*, 166 Pacific, 199. July 10, 1917.

### MINING CONTRACT—HELD MERE LICENSE

Where, under the contract between the owner of a placer claim and another, that other was to take possession of the mine, furnish machinery and material to work it, and, at the end of the first summer's work, was to have the option of continuing operations on a royalty basis, or in lieu thereof, to be paid the difference between the cost of his plant and operations and the value of the gold obtained by him, it was held that the contract was neither a conveyance nor a lease, but a mere license.

*In re Seward Dredging Co. (Alaska)*, 242 Federal, 225.

### OIL WITHDRAWAL OF 1909—APPLICATION CONSTRUED

The right of oil locators to retain their locations after the petroleum land withdrawal of 1909 depends upon the bona fides of the location and the diligence with which discovery work is prosecuted upon each location taken up. It is not enough that a lessee of an entire section prosecuted discovery work on one-quarter thereof only, with a view to drilling on the remaining quarter sections only if petroleum was found in paying quantities on the first. The withdrawal was effective as to all those sections upon which work was not actually in progress. On the other hand, delay in the work caused by the necessity of first obtaining an adequate water supply for drilling purposes, which latter work was in progress, is excusable and does not work a forfeiture.

*United States v. Brookshire Oil Co. (California)*, 242 Federal, 718.

*United States v. North American Oil Consol. (California)*, 242 Federal, 723.

*United States v. Thirty-two Oil Co. (California)*, 242 Federal, 730.

*United States v. Record Oil Co. (California)*, 242 Federal, 746.

# THE METAL MARKET

## METAL PRICES

San Francisco, December 24

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	17.00
Antimony (wholesale), cents per pound.....	16.25
Electrolytic copper, cents per pound.....	23.50
Pig-lead, cents per pound.....	6.50—7.50
Platinum, soft and hard metal, respectively, per ounce.....	\$105—113
Quicksilver, per flask of 75 lb. ....	115
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	20

The antimony market rules quiet. Business on the spot has been done at 15c., though no business of importance has been reported. Needle antimony is quoted at 9½ to 9¾c. while antimony ore is not offered at any price.

## ORE PRICES

San Francisco, December 24

Antimony, 45% metal, per unit.....	\$1.00
Chrome, 34 to 40%, free SiO <sub>2</sub> limit 8%, f.o.b. California, per unit, according to grade.....	\$0.60—0.70
Chrome, 40% and over.....	\$0.70—0.85
Magnetite, crude, per ton.....	\$8.00—10.00
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.....	26.00
Tungsten, 60% WO <sub>3</sub> , per unit.....	26.00
Molybdenite, per unit MoS <sub>2</sub> .....	\$40.00—45.00

## EASTERN METAL MARKET

(By wire from New York)

December 24.—Copper is unchanged at 23.50c. all week. Lead is quiet and steady at 6.40 to 6.50c. Zinc is inactive at 7.75c. all week. Platinum is unchanged at \$105 for soft metal and \$113 for hard.

The Anaconda Copper Mining Co. is estimated to have a net income of \$30,000,000 for 1917 after all charges and taxes. This would be \$13 per share. Such earnings compare with the net of \$50,828,373, or \$21.81 per share, in 1916. But last year was an exceptional one. There were no labor troubles. Operating costs were normal. Output was unhampered. The price of copper averaged more than 27c. per pound. This year Anaconda, like other mining companies, has had to face serious labor troubles since June. Through July and the greater part of August the properties were operated at about one-third of their capacity. The company's operation in Montana practically ceased August 25. Later the situation changed for the better, and the properties are now operating at 92% of capacity. Meanwhile abnormal costs of operation have prevailed and the peak has not yet been reached. The copper price of 23½c. fixed by the Government has obtained since October. It is estimated that Federal taxes will call for the payment of about \$4,700,000 by Anaconda. Still Anaconda will in all probability return net income within \$9 per share of the 1916 record-breaking profits of \$21.81 per share.

The few hundred holders of Phelps-Dodge Corporation stock will have received \$32 per share in dividends during 1917, comparing with \$32.50 per share last year. Production was materially affected by the shut-down due to strike at the Detroit mine for over four months and the part curtailment of Copper Queen operations early last summer. Despite this interruption production as a whole will probably exceed that of the previous year.

Half of the Inspiration Copper Co.'s mill is at work. Ten of the 22 sections are now active. Others will follow as sufficient labor becomes available. The mine lacks underground men, a dearth of experienced miners being noted since the late strike; in the mill department the company has enough men. Scouts have been sent to various labor centres in search of men.

June ....	40.26	42.07	61.93	Dec. ....	38.71	42.55	

Tin continues scarce and strong. The quotation is only nominal as practically no Straits tin is to be had. For spot 90c. is quoted, with tin for delivery in a month's time offered at prices ranging from 72 to 75c. per pound.

## ALUMINUM

There is no change in condition or demand. No. 1 virgin metal, 98 to 99% pure, is quoted at 36 to 38c. per lb., New York, for early delivery.

## ORES

Tungsten: These ores are now to come under Government regulation so far as their importation is concerned, and the obtaining of licenses and their distribution is to be regulated by the American Iron and Steel Institute, the same as in the case of tin. Considerable business has been done in the past week at \$22 to \$26 per unit in 60% concentrates, depending on the grade of ore. Scheelite has again sold at \$26 per unit. Ferro-tungsten is quoted at \$2.40 to \$2.50 per lb. of contained tungsten.

Molybdenum and antimony: There is more activity reported than in some time in molybdenite at \$2.25 to \$2.30 per lb. of MoS<sub>2</sub> in 90½ concentrates. No antimony ore has been offered.

# Eastern Metal Market

New York, December 19.

Lack of activity in all quarters characterize the markets, and less business is reported than for a long time.

Copper is unchanged at the controlled prices at which a fair business is reported.

Tin was never so scarce and is nominal for nearly all grades for early delivery.

Lead is quiet, and a little easier, and price fixing has been officially abandoned.

Zinc continues lifeless and featureless but unchanged.

Antimony is quiet and a little lower.

In the steel markets production has fallen off considerably, due to lack of fuel, poor transportation facilities, and other causes, such as the severe storms. Work has stopped on Russian locomotives, and many of those already built have not been shipped and may be used on domestic roads. The most interesting general news is that arrangements have been made whereby the American Iron and Steel Institute, representing the War Industries Board, will regulate the issuing of import licenses for ferro-alloys and the ores from which they are made, including principally chrome ore, cobalt, ferro-manganese, manganese ore, molybdenum ore, titanium ore, tungsten ore, and vanadium ore. The object of this arrangement is to secure better co-operation in obtaining imports.

## COPPER

It is generally believed now by the trade that there will be no change in the official price of copper for at least three months, although some seem to have desired an advance from 23.50c. per lb. to 25c. Official information regarding the market in general is hard to obtain, but the foregoing is generally accepted as a fact. Sales are being made to the general trade, even outside of Government work, at 23.50c. per lb., for any deliveries up to April 1, 1918. This is to large buyers. In the jobbing trade there has been considerable business done at the fixed price of 24.67½c. per lb. From one source it is estimated that production of refined copper in 1917 will exceed the total of 1916. For the first 10 months of this year the smelting output is placed at 1,645,187,271 lb., or at the rate of 164,518,727 lb. per month. At this rate it will amount to 1,975,000,000 lb. for the year, which compares with 1,927,850,548 lb. for 1916, according to the data of the U. S. Geological Survey. It seems probable that there will be sufficient metal for all consumers, as it is figured that war-needs do not require more than 75% of the output. Sales and distribution are being made under the direction of the Copper Producers' Committee and the War Trade Board to the apparent satisfaction of the entire trade. There has been no change in the London market in several weeks. Quotations there yesterday were £125 per ton for spot electrolytic, and £121 for futures.

## TIN

In our letter last week the fact was referred to that urgent representation was being made that all import restrictions in the shape of licenses, and the like, be abandoned as superfluous. This movement has failed, and on December 12 the obtaining of import licenses became necessary in order to bring in any metal. Confusion since has been general, due to the fact that it has been difficult to obtain licenses, or else because they have been much delayed. This is illustrated by the fact that tin has commenced to burden the docks since the custom houses are not permitted to accept metal until the importer has obtained his licenses. It is hoped that this serious defect

in the smooth operation of trade soon will be remedied. It is attended also with additional expenses to importers, as these cannot be saddled on to the buyer. There has been no trouble or delay with the arrangement in regard to guarantees as to purchases to be furnished by the American Iron and Steel Institute. The selling of Banca tin by a large consumer, referred to last week, has continued on a small scale to needy users. Inquiries for prompt shipment from England have continued, but there have been very few transactions because of the little metal available. As a whole, the market during the past week has been dull and uninteresting. There have been no offerings of spot Straits, which is quoted nominal at 85 to 86c. per lb., New York. Arrivals to December 16, inclusive, have been 1015 tons, with 4400 tons reported afloat. Spot Straits in London continues to advance, the quotation yesterday having been £6 higher than a week ago, or £305 per ton.

## LEAD

For the present there will be no fixing of lead prices, according to the following statement given out on Tuesday after a meeting of lead producers and the War Industries Board: "The principal lead producers of this country at the invitation of the War Industries Board met with the Board this morning in Washington to discuss the advisability of putting restrictions upon the price and distribution of lead. After a protracted conference, and thorough consideration of the facts brought out in conference, the War Industries Board does not consider that regulatory action is at this time necessary or advisable." This decision comes as entirely unexpected, because a maximum price was regarded as probable. It is generally interpreted as meaning that there is ample lead for all needs and a probability that fair prices will continue. Domestic business the past week has been light, and the tone has been easier, with sales at 6.40c., New York, or 6.25c., St. Louis. The quotation of the leading producer is unchanged at 6.25c., New York. There has been an improvement in export inquiry. It is understood that negotiations are on as to a further supply for the Government.

## ZINC

It is the same old story in the zinc market, with no prospect of any resuscitation. While there has been some buying recently by galvanizers, it has not been large because production of this commodity is at a low mark. Demand from this source, however, has been a little better recently. Nor have brass-makers been over-eager to purchase zinc of any grade. Quotations are low at 7.50c., St. Louis, or 7.75c., New York, for prime Western for early delivery, and the only fact that keeps them from going lower is that they are at or below the cost of production in many cases. Production is gradually lessening, but is still in excess of the demand. Considerable interest attaches to the opening of bids this week, Friday, by the Government on 1000 tons of grade 'C' zinc, which is only a little better than regular prime Western. Reports are persistent to the effect that railroad congestion is seriously interfering with the filling of contracts, especially for export. Price-fixing of zinc is not expected now because of the official decision not to regulate the lead market as announced on Tuesday, December 18.

## ANTIMONY

Chinese and Japanese grades are quoted at 15c. per lb., duty paid, New York, for early deliveries, but demand is not large, and the market is quiet and featureless.

# INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

## K & K FLOTATION MACHINE

The K & K flotation machine, whether constructed of wood or steel, consists of a cylindrical housing about 10 ft. long and 26 in. diam., to the front of which is attached a V-shaped compartment called the frothing-chamber. The frothing-chamber is provided with a lip, over which the concentrate is discharged into a suitable launder. Inside the cylindrical housing or aeration-chamber is the rotor, which consists of a  $3\frac{7}{8}$ -in. steel shaft, on which is mounted four cast-iron spiders, carrying the lagging and riffles of the rotor. The rotor is supported by two main bearings at each end of the machine. Self-

air-slots of the rotor, coming in contact with and thoroughly aerating the revolving pulp in the space between the periphery of the rotor and the inner surface of aeration-chamber. The pulp enters at one end of the machine and is discharged at the opposite, thus passing through the machine for a distance of 10 ft.; it is also caused to revolve through the aeration-chamber. These two movements cause the feed to travel in the path of a helix in the course of which it is thoroughly aerated, forming a froth which carries the mineral, this mineral-laden froth being discharged over the lip of the frothing-chamber, while the tailing is discharged at the other end of the machine. An adjustable device for maintaining the level

is provided, and this insures the correct height of the bubble-column in the frothing-chamber. As may be seen from the foregoing description, the feed enters at one end of the machine, the tailing being discharged at the opposite end, while the concentrate is delivered over the lip of the frothing-chamber into a suitable launder. The machine, therefore, is a complete unit. The operation is continuous, the machine itself furnishing a horizontal and circular path for the feed, during which the aeration takes place, the frothing is produced, and the tailing and concentrate are discharged.

The steel machine is constructed of No. 10 steel-plate with end-pieces of  $\frac{1}{2}$ -in. plate, mounted on a structural-steel base composed of three 5-in. I-beams, on which are fastened the two main bearings. The housing over the rotor is constructed of rolled plate reinforced with angle-bars, and is so arranged that it can be removed for replacing the hardwood riffles. These last from four to six months. The steel machine is recommended for feeds that contain no excessive amount of acid. In cases where much acid is present the wooden type is recommended. Each machine is provided with a pulley for driving from a line-shaft, but may also be driven by direct connection to an electric motor or to other power. The floor-space required is 4 by 14 ft., and the head-room about 3 ft. The capacity of the machine is 80 to 150 tons per 24 hr., and it requires from 6 to 8 hp. to operate. The weight of the steel machine is 3500 lb. and of the wooden type 3300 pounds.

## COMMERCIAL PARAGRAPHS

The SULLIVAN MACHINERY Co.'s offices in Salt Lake City have been removed to new and larger quarters in the Walker Bank building. The Utah agency of the Sullivan company is under the management of Burt B. Brewster.

The BORDEN COMPANY announces its 1918 catalogue of Beaver easy-working die stocks and square-end pipe cutters. Several new tools are shown in this book, which is beautifully printed and illustrates artistically the entire line of Beaver easy-working tools.

WALTER A. ZELNICKER SUPPLY Co. of St. Louis, has just secured the services of L. B. Moses, who has been closely associated with the rail-trade since 1903. He left the position of

GENERAL VIEW OF K & K MACHINE

aligning S. K. F. ball bearings are used and set in a grit-proof housing. The lagging forming the periphery of the rotor is so spaced as to leave a  $\frac{1}{4}$ -in. opening or slot between each piece. There are 21 pieces, and each one is provided with three hardwood riffles, extending the entire length of the rotor, which is about 10 ft. long. The rotor makes 200 r.p.m., and has a clearance of  $\frac{3}{8}$  in. between the periphery and the inner surface of the aeration-chamber. The shaft on which the rotor is mounted passes through the two end-plates of the machine by means of two air-ducts, 14 in. diam. and 13 in. long. These air-ducts are of ample size to furnish all the air from the atmosphere that is necessary to thoroughly aerate the pulp as it is revolved between the outer riffled surface of the rotor and the inner surface of the aeration-chamber. There is no leakage of pulp through the air-ducts, but, on the contrary, a continuous inflow of air from atmosphere. The air is discharged by centrifugal force through the air-slots, between each of the 21 pieces of riffled lagging forming the periphery of the rotor, and it immediately comes into contact with a thin film of pulp, circulated by the revolving rotor.

The frothing-box is provided with suitable partitions and openings which, with the level-control device, result in the skimming of a thin film from the surface of the riffled rotor. This film is supplied with air, which passes in through the air-ducts at each end of the machine and out through the

assistant to the president of the Kansas City Southern Ry., at that time to become sales manager for the Kettle River Co. of Minneapolis. Mr. Moses joins the Zelnicker organization as second vice-president, in charge of the rail department, with headquarters at the company's main offices at St. Louis. The same company has issued bulletin No. 232, listing hoisting engines, wire-rope, locomotives, cars, trucks, derricks, skidders, and loaders, all ready to ship. The hoists are both electric and steam driven.

Cho Ito & Co., of Kobe, Japan, has opened a branch office at Seattle, Washington, and will conduct a general import and export business on a large scale. Mr. Ito, the head of the firm, is the principal director in the Ocean Transport Co. of Kobe, operating a fleet of vessels between Japan and American ports. He is also an owner in many mines in the Orient. The firm desires correspondence with buyers and sellers of antimony, antimony regulus, and ores, zinc dust, manganese and chrome ores, and molybdenum.

The INGERSOLL-RAND Co. has issued an exceedingly attractive bulletin, No. 3118, superseding No. 3018, dealing with compressors and vacuum-pumps for the extraction of gasoline from natural gas. The bulletin gives a simple statement of the method of the gasoline-extraction process, with a description of a gasoline-extraction plant accompanied with plans as well as illustrations. It is a booklet that will be interesting to all producers of oil. The firm has also issued bulletin No. 9024, dealing with steam-condensing plants, also taking up the Beyer barometric counter-current condensers, the Ingersoll-Rand dry air pumps, and Cameron water pumps.

E. I. DU PONT DE NEMOURS & Co. has issued a circular calling attention to nitre-cake, which is a by-product in the manufacture of sulphuric acid. Being an acid sodium sulphate, there is an available acidity which may be stated in terms of equivalent sulphuric acid. The nitre-cake which the Dupont company is offering to the chemical market, when dissolved in hot water, yields an acid solution equivalent approximately to an 18% solution of free sulphuric acid. A long list is given of practical uses for nitre-cake as a substitute for free acid, which will be of interest to a large number of manufacturers and operators. The circular will be mailed on application, and may result in pointing a way to save money.

J. C. Bannister has been made a vice-president of the WALWORTH MANUFACTURING Co. of Boston, Massachusetts, manufacturers of iron-pipe fittings, valves, stillson wrenches, and similar supplies. Mr. Bannister has been connected with the manufacture of products of this class for 26 years, starting as foreman of the tapping department of the Haxtun Steam Heater Co., at Kewanee, in 1891. He advanced to superintendent of the pipe-finishing mill, and then to chief engineer. For three years he was superintendent of the Kewanee Boiler Co., when the National Tube Co. took over the operation of the Kewanee plant, and Mr. Bannister was made the manager. The Walworth Manufacturing Co. purchased the Kewanee works in August 1917 and Mr. Bannister has now been made a vice-president of that company, although his headquarters will still be at Kewanee, Illinois, and no change in the management there is contemplated at present.

MEXICAN BUSINESS IS GROWING. The U. S. Department of State has gone so far as to approve an institution which is called an American Chamber of Commerce of Mexico, S. C. L., which has opened offices in Mexico City. The honorary president is the American ambassador to Mexico, Henry P. Fletcher, while G. A. Chamberlain, our consul general at Mexico City, and John Barrett, director general of the Pan-American Union, are honorary vice-presidents. The active officers are S. W. Rider, president; Frank Sanborn and Arnold Shanklin, vice-presidents; K. M. Van Zandt, Jr., treasurer; and C. B. Parker, acting secretary. The Chamber will publish printed matter

regarding the country and its resources, and plans are being made for issuing a periodical market reporter and news bulletin, which should interest manufacturers and others in this country seeking to do business across the border. The Chamber will maintain a reading-room with American newspapers and magazines on file.

TATE, JONES & Co., Inc., furnace engineers, Pittsburgh, have just issued bulletin No. 160, describing their recuperative gas-oven furnaces, which are made for all industrial purposes where oil and gas-fired furnaces are required, such as annealing, tool dressing, blacksmithing, bolt-heading, drop-forge, rivet-rod, pipe-bending, heat-treating, and hardening furnaces, both large and small, according to the class of work to be done. The furnace is scientifically constructed, and careful consideration has been given to the question of refractories and insulation, so that the fuel-economy is a point that has been thoroughly worked out. With the chamber at 1600°F., and the furnace working under equilibrium, the outside temperature of the brick is 450°, so that such a wall will permit only 5.2 B.t.u. per hour to pass per square inch of surface. The furnaces are equipped with thermo-couples to enable the operator to maintain the exact temperature required, and the company is prepared to guarantee a saving in fuel over the non-recuperative furnace of 20%, even when operating at temperatures as low as 1300° Fahrenheit.

The new editions of the catalogues of the GOULDS MANUFACTURING Co. are No. 100, 105, 107, 114, 115, and 116. Bulletin No. 100 has reached its eighth edition. This relates to single central double-cutting piston pumps. The Goulds pumps are universally known, and include practically every type required in engineering work and in the arts. An interesting feature of the Goulds catalogue is bulletin No. 112. It is devoted exclusively to handy data on power pumping, and constitutes a volume of practical engineering data for figuring the problems involved in pumping, piping, and general hydraulics as related to such problems, together with mathematical and electrical tables, all of which will be most useful for ready reference. One of the notable types of pump is the Gould multi-stage centrifugal, which is described in bulletin No. 120. The performance of a No. 6 three-stage pump is cited as an example, the curves plotted from the tests show that for a capacity of 1000 gal. per minute it will generate a head of 445 ft., with an efficiency of 72%, requiring 156 hp., pumping 700 gal. per minute. The pump is able to produce a pressure of 505 ft., with an efficiency of 65%, requiring 137 hp. By closing the discharge valve entirely, the point of no delivery, called the 'shut-off' of the pump, is reached. The head-curve at this point is 533 ft. in contrast with a reciprocating pump; the discharge valve can be closed entirely, and the pump will produce a 'shut-off' pressure which will be only 10 to 30% greater than the pressure at the rating given to the impeller design. This 'shut-off' point is actually somewhat higher in case the pump is driven by an independent motor or turbine, as with this kind of prime-mover the speed will increase as the load decreases. Pumping against no head gives the maximum capacity of the pump, in this case approximately 1550 gal. per minute. From the b-hp. curve it is seen that the curve reaches its peak at a point coinciding approximately with the maximum efficiency. In other words, if a motor be chosen with about 10% surplus power above that required at its most efficient rating, which, in this case, is between 1000 and 1050 gal. per minute, that motor cannot be overloaded or otherwise damaged by any change in the head against which the pump will operate. This is called a non-overload impeller. Reducing the capacity also decreases the power consumption. Power therefore can be saved by throttling the discharge valve until just the desired quantity of water is obtained. At the point of no delivery about 90% is required to rotate the impellers.
